The ſeeds of this plant ſhould be ſown in ſmall pots filled with light ſandy earth, ſoon after they are ripe, and plunged into a moderate hot-bed, and muſt be frequently but gently watered; ſometimes the ſeeds will lie a long time in the ground, ſo that if the plants do not appear the ſame ſeaſon, the pots ſhould not be diſturbed, but preſerved in ſhelter till the following ſpring, and then plunged into a freſh hot-bed, which will bring up the plants in a ſhort time, if the ſeeds are good. When the plants are fit to remove, they ſhould be tranſplanted into ſmall pots, four or five in each pot; then plunge the pots into a moderate hot-bed, and ſprinkle them with water, and ſhade them every day from the ſun till they have taken new root; after which they muſt have a large ſhare of air in warm weather, to prevent their drawing up weak: when the plants have obtained ſome ſtrength, they muſt be gradually inured to bear the open air; but when they are expoſed abroad, if there ſhould happen much rain, the plants muſt be ſcreened from it, otherwiſe it will cauſe them to rot: when the plants have filled the pots with their roots, they ſhould be parted, and each put into a ſeparate pot filled with light ſandy earth, not rich with dung, placing them in the ſhade till they have taken freſh root; then they may be removed to a warm ſheltered ſituation, and mixed with ſuch other plants as require but little water; in which ſituation they may remain till autumn, when they muſt be placed in a dry airy glaſs-caſe; and in the winter ſhould have very little wet, but muſt enjoy the ſun as much as poſſible; and in mild weather ſhould have freſh air admitted to them, but muſt be protected from froſt: with this management, the plants will thrive and produce flowers the ſecond year from ſeed.

The ſecond ſort riſes with a firmer ſtalk than the firſt, which is round, jointed, and divides upward into a greater number of branches, garniſhed with ſhort narrow leaves, which are pretty thick and ſucculent. The flowers are produced at the end of the branches, in the ſame manner as thoſe of the firſt, which are of a fine red colour, but not half ſo large as the flowers of the firſt; when theſe fall away, they are ſucceeded by oval pulpy berries, in which are included many ſmall ſeeds. This ſort continues flowering great part of ſummer and autumn, and in warm ſeaſons the ſeeds will ripen in England.

It is propagated by ſeeds in the ſame manner as the former ſort, and the plants require the ſame treatment.

CHIVES, as they are by ſome titled, are the ſtamina, which ſupport the ſummits in the center of flowers.

CHIVETS, in French, are the ſmall parts, or little offſets from the roots of bulbous plants, by which they are propagated.

CHONDRILLA. Lin. Gen. Plant. 815. Tourn. Inſt. R. H. 475. tab. 268. [of Χόνδρος, *Gr.* a cartilage.] Gum Succory.

The Characters are,

The common empalement is compoſed of many narrow cylindrical ſcales, which are equal. The flower is compoſed of many hermaphrodite florets, which are uniform, and lie imbricatim, like tiles on a houſe; theſe have one petal, which is ſtretched out on one ſide like a tongue, and are indented at the top in four or five ſegments; they have each five ſhort hairy ſtamina, terminated by cylindrical ſummits. The germen is ſituated under the floret, having a ſtyle the length of the ſtamina, crowned by two reflexed ſtigmas; the germen afterward becomes a ſingle, oval, compreſſed ſeed, crowned with a ſingle down, and incloſed in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia æqualis. The flowers of this ſection are compoſed of only hermaphrodite florets, which are fruitful.

We have but one Species of this genus, viz.

Chondrilla (*Juncea.*) Lin. Hort. Cliff. 383. *Gum Succory.* Chondrilla juncea viſcoſa arvenſis. C. B. P. 30. *Viſcous Field Gum Succory with ruſhy ſtalks.*

This plant grows naturally in Germany, Helvetia, and France, on the borders of the fields, and is ſeldom preſerved in gardens, becauſe the roots are very apt to ſpread, and become troubleſome weeds; and the ſeeds having down on their tops, are carried by the wind to a great diſtance, ſo that the neighbouring ground is filled with the plants; the roots of this ſtrike deep into the ground, and ſpread out with thick fibres on every ſide, each of which, when cut, or broken into many parts, will ſhoot up a plant; ſo that when this plant hath obtained poſſeſſion of the ground, it is very difficult to root out. The root ſends out a great number of ſlender ſtalks, which at their bottom are garniſhed with oblong ſinuated leaves, but thoſe above are very narrow and entire. The flowers are produced from the ſide and top of the branches, which are like thoſe of Lettuce, and are ſucceeded by ſeeds of the ſame form, crowned with down. It flowers in July, and the ſeeds ripen in September.

The other ſpecies of this genus which were enumerated in the former edition, are referred to the Lactuca and Crepis.

CHRISTMAS FLOWER, or Black Hellebore. See Helleborus.

CHRISTOPHORIANA. See Actea.

CHRISANTHEMOIDES OSTEOSPERMON. See Osteospermum.

CHRYSANTHEMUM. Tourn. Inſt. R. H. 491. tab. 280. Lin. Gen. Plant. 866. Leucanthemum. Tourn. Inſt. R. H. 492. [χρυσάνθεμον, *Gr.* from χρυσος, gold, ἄνθεμος, a flowet; that is to ſay, Golden Flower.] Corn Marigold.

The Characters are,

It hath a compound flower, the rays being compoſed of female florets, which are extended on one ſide like a tongue, and are indented in three ſegments at the end; theſe have an oval germen, ſupporting a ſlender ſtyle, crowned by two obtuſe ſtigmas. The hermaphrodite florets which compoſe the diſk, are funnel-ſhaped the length of the empalement, but are divided into five ſegments at the top, which are ſpread open; theſe have five ſhort hairy ſtamina, terminated by tubular cylindrical ſummits, and have an oval germen, with ſtyle and ſtigma like the female; the germen afterward becomes a ſingle, oblong, naked ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia ſuperflua. In this ſection all the central florets which compoſe the diſk, are hermaphrodite and fruitful, and the rays are compoſed of female florets.

The Species are,

1. Chrysanthemum (*Segetum*) foliis amplexicaulibus, ſupernè laciniatis, infernè dentato-ſerratis. Hort. Cliff. 416. *Corn Marigold with leaves embracing the ſtalks, the upper being jugged, and the lower indented like a ſaw.* Chryſanthemum ſegetum. Cluſ. Hiſt. 1. p. 334. *Corn Marigold.*
2. Chrysanthemum (*Leucanthemum*) foliis amplexicaulibus, oblongis, ſupernè ſerratis, infernè dentatis. Hort. Cliff. 416. *Corn Marigold with oblong leaves embracing the ſtalks, the upper ones being ſawed, and the lower indented.* Bellis ſylveſtris caule folioſo major. C. B. P. 261. *Greater wild Daiſy with a leafy ſtalk.*
3. Chrysanthemum (*Serotinum*) foliis lanceolatis, ſupernè ſerratis, utrinque acuminatis. Hort. Cliff. 416. *Corn Marigold with ſpear-ſhaped leaves, thoſe above being ſawed, and pointed on all ſides.* Bellis major, radice repente, foliis latioribus, ſerratis. Mor. Hiſt. 3. p. 29. *Greater Daiſy with a creeping root, and broad ſawed leaves.*
4. Chrysanthemum (*Montanum*) foliis imis ſpathulato-lanceolatis, ſerratis, ſummis linearibus. Sauv. Monſp. 87. *Corn Marigold with lower leaves pointed like a ſpear-ſhaped ſpatula, and ſawed, and the upper ones linear.* Leucanthemum montanum minus. Tourn. Inſt. 492. *Leſſer Mountain Ox-eye.*
5. Chrysanthemum (*Graminifolium*) foliis linearibus, ſubintegerrimis. Sauv. Monſp. 87. *Corn Marigold with narrow leaves, which are entire.* Leucanthemum gramineo folio. Tourn. Inſt. 493. *Ox-eye with a Graſs leaf.*
6. Chrysanthemum (*Alpinum*) foliis pinnatifidis, laciniis parallelis, integris, caule unifloris. Lin. Sp. Plant. 889. *Corn Marigold with many pointed leaves, whoſe ſegments are parallel and entire, and one flower on each foot-ſtalk.* Leucanthemum Alpinum, foliis Coronopi. Tourn. Inſt. R. H. 493. *Alpine Ox-eye with a Hartſhorn leaf.*

7. **Chryſanthemum** (*Corymbiferum*) foliis pinnatis, inciſo-ſerratis, caule multifloro. Prod. Leyd. 174. *Corn Marigold with winged leaves, ſawed ſegments, and many flowers upon a ſtalk.* Tanacetum montanum inodorum, minore flore. C. B. P. 132. *Unſavoury Mountain Tanſy with a leſſer flower.*

. **Chryſanthemum** (*Coronarium*) foliis pinnatifidis, inciſis, extrorſum latioribus. Hort. Cliff. 416. *Corn Marigold with wing-pointed cut leaves, whoſe exterior parts are broadeſt.* Chryſanthemum Creticum. Cluſ. Hiſt. 1. p. 334. *Corn Marigold of Crete.*

9. **Chryſanthemum** (*Monſpelienſium*) foliis imis palmatis, foliolis linearibus, pinnatifidis. Sauv. Monſp. 304. *Corn Marigold, whoſe lower leaves are palmated, and the ſmaller linear, ending in many points.* Leucanthemum montanum foliis Chryſanthemi. Tourn. Inſt. 492. *Mountain Ox-eye with Corn Marigold leaves.*

10. **Chryſanthemum** (*Fruteſcens*) fruticoſum, foliis linearibus dentato-trifidis. Hort. Cliff. 417. *Shrubby Corn Marigold with narrow leaves, having three indented points.* Leucanthemum Canarienſe, foliis Chryſanthemi, Pyrethri ſapore. Tourn. Inſt. 493. *Canary Ox-eye with Corn Marigold leaves, and the taſte of Pellitory.*

11. **Chryſanthemum** (*Floſculoſum*) floſculis omnibus uniformibus, hermaphroditis. Hort. Cliff. 417. *Corn Marigold, whoſe florets are all uniform and hermaphrodite.* Bellis ſpinoſa, foliis Agerati. C. B. P. 262. *Prickly Daiſy with Maudlin leaves.*

12. **Chryſanthemum** (*Pallidum*) foliis linearibus, inferne apice dentatis, ſuperne integerrimis, pedunculis nudis unifloris. *Corn Marigold with narrow leaves, thoſe on the lower part being indented at their points, the upper entire, and naked foot-ſtalks with one flower.* Chryſanthemum pallidum minimis, imiſque, foliis inciſis ſuperioribus integris, capillaribus. Barrel. Icon. 421. *Leaſt Corn Marigold, with the under and leſſer leaves divided, the upper entire.*

The firſt ſort is the common Corn Marigold, which grows naturally amongſt the corn, and the borders of the corn-fields in divers parts of England, ſo is rarely admitted into gardens; but we have inſerted this and the next to introduce the other ſpecies.

The ſecond ſort is the greater Daiſy, which ſtands in the liſt of medicinal plants in the College Diſpenſatory: this grows naturally in moiſt paſtures, almoſt every where in this country. It riſes with ſtalks near two feet high, garniſhed with oblong indented leaves, which embrace the ſtalks with their baſe. The footſtalks are each terminated by one white flower, ſhaped like thoſe of the Daiſy, but four times as large. It flowers in June.

The third ſort grows naturally in North America, but hath been long preſerved in the Engliſh gardens. The roots of this plant creep far under the ſurface, and ſend up ſtrong ſtalks three or four feet high, garniſhed with long ſawed leaves, ending in points; the ſtalks divide upward into many ſmaller, each being terminated by a large, white, radiated flower; theſe appear in September. It multiplies very faſt by its creeping roots, and will thrive in any ſoil or ſituation.

The fourth ſort grows naturally upon the Alps, and other mountainous places. I received this from Verona, near which place it grows in plenty: this ſends up a ſingle ſtalk a foot high, garniſhed with entire leaves above, but the under leaves are ſawed on the edges. The ſtalk is terminated by one large white flower, ſhaped like thoſe of the third ſort. It flowers in June, and the ſeeds ripen in Auguſt. This ſort may be propagated by ſeeds, which, if ſown in a ſhady border, will come up in about ſix weeks; and the plants, when fit to remove, may be tranſplanted into a ſhady border, where they are to remain, and will require no other care but to keep them clean from weeds.

The fifth ſort grows naturally about Montpelier; this hath a perennial root, from which ſprings up many narrow Graſs-like leaves, and, between them, ſtalks which riſe a foot and a half high, garniſhed with leaves of the ſame form as thoſe below. The ſtalks are each terminated by one large white flower, with a yellow diſk or middle. This flowers in June, but rarely perfects ſeeds in England, ſo is propagated only by parting the roots: the beſt time for this is in autumn, that the plants may get good root before winter.

The ſeventh ſort grows naturally on the Alps, and other mountainous places in Germany: this ſends out upright ſtalks, garniſhed with leaves cut into many parallel ſegments, ſomewhat like thoſe of Buckſhorn Plantain. The ſtalks riſe a foot and a half high, and are each terminated by a ſingle flower of the ſame form with thoſe of the laſt: it hath a perennial root, and may be propagated in the ſame manner as the other.

The eighth ſort has been many years cultivated in the gardens for the beauty of its flowers. Of this there are ſingle and double with white, and the ſame with yellow flowers; and as theſe do not differ from each other in any thing except in the colour of their flowers, therefore they are generally eſteemed but one ſpecies; but this difference is conſtant, for I have never found the ſeeds ſaved from the white, produce plants with yellow flowers, nor thoſe of the yellow produce white.

There is alſo a variety of theſe colours with fiſtular florets, which has accidentally riſen from ſeeds of the other; theſe are generally titled Quill-leaved Chryſanthemum; but as the ſeeds ſaved from theſe degenerate to the common ſorts, ſo they do not merit a particular denomination.

Theſe plants are always eſteemed as annual, ſo the ſeeds are uſually ſown upon a ſlender hot-bed in the ſpring, and the plants treated in the ſame manner as the African Marigold, for the culture of which we ſhall refer the reader to that article; but as the plants which riſe from ſeeds, do many of them produce ſingle flowers, although the ſeeds are ſaved from the beſt double flowers, therefore many perſons now propagate theſe plants from cuttings, whereby they continue the double ſorts only; theſe cuttings, taken from the plants the beginning of September, and planted in pots, will readily take root; and if they are placed under a hot-bed frame to ſcreen them from the froſt in winter, letting them have free air in mild weather, they will live through the winter; and in the ſpring theſe plants may be tranſplanted into the borders of the flower-garden, where they will flower in June, and continue in ſucceſſion till the froſt puts a ſtop to them; by this method all the varieties may be continued without variation, but the plants which are propagated this way by cuttings will become barren ſoon, ſo will not produce ſeeds.

The ninth ſort is a perennial plant, ſending out many ſtalks from the root, which divide into branches, garniſhed with pretty thick leaves, deeply cut into many ſegments, like thoſe of the laſt ſort; theſe are of a pale green; the flowers are produced at the end of the branches, ſtanding upon pretty long naked footſtalks; they are very like thoſe of the common Greater Daiſy, in ſize and colour. It flowers in June, and continues till the end of September. This ſort ripens ſeeds every year in England, by which the plant is eaſily propagated; for if the ſeeds are ſown in the ſpring on a common border, the plants will come up in ſix weeks; when theſe are fit to remove, they may be tranſplanted into a nurſery-bed at about a foot diſtance every way, and kept clean from weeds till autumn, when they may be removed to the places where they are deſigned to remain. As theſe plants extend their branches pretty far on every ſide, they ſhould be allowed at leaſt two feet room; therefore they are not very proper furniture for ſmall gardens, where there is not room for theſe large growing plants; but in large gardens, theſe may have a place for the ſake of variety.

If theſe plants are planted in poor dry land, or upon lime-rubbiſh, they will not grow ſo vigorous as in good ground, ſo they will endure the cold better, and continue longer; for when their leaves and branches are replete with moiſture, they are very apt to rot in the winter, ſo are ſeldom of long duration; but where the plants have grown from the joints of old walls, I have known them continue in vigour ſeveral years.

The tenth ſort grows naturally in the Canary Iſlands, from whence it was firſt brought to England, where it has been long an inhabitant in ſome curious gardens. It has been frequently called by the gardeners Pellitory of Spain, from the very warm taſte which it hath, much reſembling the taſte of that plant.

This riſes with a ſhrubby ſtalk near two feet high, dividing into many branches, garniſhed with pretty thick ſucculent leaves, of a grayiſh colour, cut into many narrow ſegments, which are divided into three parts at their extremity. The flowers come out from the wings of the leaves, ſtanding upon naked foot-ſtalks ſingly, which greatly reſemble thoſe of the common Chamomile; there is a ſucceſſion of flowers upon the ſame plants great part of the year, for which it is chiefly eſteemed. This plant will perfect ſeeds in England, when the ſeaſons are favourable; but as the cuttings of it take root ſo eaſily, if planted during any of the ſummer months, the ſeeds are rarely ſown.

As this plant is a native of warm countries, it will not live in the open air in England during the winter ſeaſon; therefore when the cuttings have made good roots, they ſhould be each planted into a ſeparate pot, and placed in the ſhade till they have taken freſh root; then they may be removed to a ſheltered ſituation, where they may remain till autumn, at which time they muſt be removed into the green-houſe to protect them from froſt; but in mild weather they ſhould have plenty of free air, and, during the winter, they ſhould be frequently refreſhed with water, but it muſt not be given them in too great plenty. In ſummer they will require more moiſture, and ſhould be treated in the ſame manner as other hardier kinds of exotic plants.

The eleventh ſort grows naturally at the Cape of Good Hope, from whence the ſeeds were brought many years paſt to Holland, where the plants were firſt raiſed, and from thence all the other parts of Europe have been ſupplied with this plant. It riſes with a ſhrubby ſtalk about two feet high, which divides into many ſlender branches upward, garniſhed with oblong leaves, much indented on their edges, each indenture terminating in a ſoft ſpine; theſe are of a pale green, ſet cloſe to the branches. The flowers are produced on ſhort foot-ſtalks from the wings of the leaves, toward the upper part of the branches; theſe are globular, and formed of a great number of hermaphrodite florets, which are tubular and even, having no rays, ſo are naked, and of a deep yellow colour. The flowers appear in June, and continue in ſucceſſion till the froſt ſtops them. This may be propagated by cuttings in the ſame manner as the laſt, and the plants ſhould be treated in the ſame way.

The twelfth ſort grows naturally about Madrid: this hath a low ſhrubby ſtalk, which ſeldom riſes a foot high, putting out ſeveral ſlender ligneous branches, garniſhed with narrow, pale, green leaves; thoſe on the lower part of the branches are indented at their extremity in ſeveral parts, but the upper leaves are entire; from the end of each branch is produced a naked foot-ſtalk ſix inches long, ſuſtaining one radiated flower, of a ſulphur colour. The flowers come out in June and July, but there is ſeldom any ſeeds ripened in England; this ſort muſt be ſheltered under a common frame in winter, for unleſs the winter proves very favourable, the plants will not live in the open air here. It may be propagated by cuttings in ſummer, as the two laſt ſorts, but theſe cuttings do not ſo readily take root as thoſe do.

CHRYSOBALANUS. Lin. Gen. Plant. 585. Icaco. Plum. Nov. Gen. 44. Cocoa Plumb.

The CHARACTERS are,

The empalement of the flower is of one leaf, divided into five parts, almoſt to the middle. The flower hath five petals, which ſpread open, and ten ſtamina, five of which are longer than the petals; the other are ſhorter, and are terminated by heart-ſhaped ſummits. In the center is ſituated an oval germen, ſupporting a trifid ſhort ſtyle, crowned by obtuſe ſtigmas. The germen afterward becomes an oval fleſhy berry, incloſing a nut with five longitudinal furrows.

This genus of plants is ranged in the firſt ſection of Linnæus's thirteenth claſs, intitled Polyandria Monogynia; but it would be more properly placed in the third ſection of his tenth claſs, for the flowers have ten ſtamina and three ſtyles.

The SPECIES are,

1. CHRYSOBALANUS (*Icaco*) foliis ovatis, emarginatis, floribus racemoſis, caule fruticoſo. *Chryſobalanus with oval indented leaves, flowers growing in bunches, and a ſhrubby ſtalk.* Frutex Cotini ferè folio craſſo, in ſummitate deliquium patiente, fructu ovali cæruleo oſſiculum anguloſum continente. Cateſb. Car. *The Cocoa Plumb.*
2. CHRYSOBALANUS (*Purpurea*) foliis decompoſitis, foliolis ovatis integerrimis. *Chryſobalanus with decompounded leaves, whoſe lobes are oval and entire.* Icaco fructu purpureo. Plum. Nov. Gen. 44. *Icaco with purple fruit.*

The firſt ſort grows naturally in the Bahama Iſlands, and in many other parts of America, but commonly near the ſea. It riſes with a ſhrubby ſtalk about eight or ten feet high, ſending out ſeveral ſide branches, covered with a dark brown bark, ſpotted with white; theſe are garniſhed with oval ſtiff leaves, which are indented at the end, in form of a heart, placed alternately on the branches. From the wings of the leaves, and alſo at the diviſion of the branches, the flowers are produced, which grow in looſe bunches; theſe are ſmall and white, having many ſtamina in each, which are joined to the petals of the flowers, terminated by yellow ſummits. The flowers are ſucceeded by oval Plumbs about the ſize of Damſons; ſome of theſe are blue, ſome red, and others yellow; they have a ſweet luſcious taſte. The Spaniards in the iſland of Cuba, make a conſerve of theſe fruits. The ſtone of the Plumb is ſhaped like a Pear, and hath five longitudinal ridges on it. This grows naturally on moiſt land.

The ſeeds of the ſecond ſort were ſent me from Jamaica, with Plumier's title; the ſtones were exactly the ſame ſhape of thoſe of the former, but the plants have leaves compounded of ſeveral winged lobes, which are branched out oppoſite, each having ſix or ſeven pair of pinnæ (or lobes.) This ſort hath not flowered in England, ſo I can give no farther account of it.

As theſe trees are natives of the warm parts of America, ſo they will not thrive in England, unleſs they are kept in a warm ſtove. They are propagated by ſeeds, which muſt be obtained from the countries where the plants naturally grow; theſe muſt be ſown in the ſpring in ſmall pots filled with light earth, and plunged into a hot bed of tanners bark, obſerving frequently to water the pots; but not let them have much at each time. In ſix weeks the plants will come up, and, if properly managed, will be fit to remove in a month's time after, when they ſhould be carefully ſeparated, and each planted into a ſeparate ſmall pot filled with light kitchen-garden earth, and then plunged into the hot-bed again, obſerving to ſhade them from the ſun till they have taken freſh root; after which they muſt have air every day in proportion to the warmth of the ſeaſon, and their waterings during the ſummer ſhould be frequent, but ſparing. In the autumn the plants muſt be removed into the bark-ſtove, and plunged into the tan-bed; and in winter the plants muſt not have too much water, leſt it occaſions their throwing off their leaves. In ſummer they muſt have a good ſhare of air, and the plants in the ſtove ſhould be conſtantly treated in the ſame manner as other tender plants from the ſame countries.

CHRYSOCOMA. Lin. Gen. Plant. 845. Dillen. Gen. 14. Coma aurea. Boerh. 1. p. 121. Goldylocks.

The Characters are,

The common empalement is imbricated, the ſcales are narrow, the outer being convex and pointed; the flower is compoſed of many hermaphrodite florets, which are tubular, equal, and funnel-ſhaped, cut into five ſegments at the brim, which turn back; theſe have each five ſhort ſlender ſtamina, terminated by cylindrical ſummits; they have an oblong germen, ſupporting a ſlender ſtyle, crowned by two oblong depreſſed ſtigmas. The germen afterward becomes a ſingle, oblong, compreſſed ſeed, crowned with hairy down.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia Æqualis; the plants of this ſection have only hermaphrodite florets, which are fruitful.

The Species are,

1. Chryſocoma (*Linoſyris*) herbacea, foliis linearibus, glabris, calycibus laxis. Lin. Sp. Plant. 841. *Herbaceous Goldylocks with narrow ſmooth leaves, and looſe empalements.* Coma aurea Germanica linariæ folio. Park. Theat. 688. *German Goldylocks.*
2. Chryſocoma (*Biflora*) herbacea paniculata, foliis lanceolatis trinerviis, punctatis, nudis. Lin. Sp. Plant. 841. *Herbaceous Goldylocks with flowers growing in panicles, and ſpear-ſhaped leaves, having three nerves, and yellow flowers growing in umbels.*
3. Chryſocoma (*Coma Aurea*) fruticoſa foliis linearibus dorſo decurrentibus. Hort. Cliff. 397. *Shrubby Goldylocks with very narrow leaves, whoſe back parts run along the ſtalks.* Coma aurea Africana fruticans, foliis linariæ anguſtis, major. Com. Hort. Amſt. 2. p. 89. *Greater ſhrubby African Goldylocks, with narrow Toad-flax leaves.*
4. Chryſocoma (*Cernua*) ſubfruticoſa, foliis linearibus ſubtus piloſis, floribus ante floreſcentiam cernuis. Hort. Cliff. 397. *Shrubby Goldylocks with very narrow hairy leaves, and flowers nodding before they are blown.* Coma aurea foliis linariæ anguſtioribus minor. Hort. Amſt. 2. p. 89. *Leſſer Goldylocks with narrower Toad-flax leaves.*
5. Chryſocoma (*Ciliata*) ſuffruticoſa, foliis linearibus rectis, ciliatis ramis pubeſcentibus. Lin. Sp. Plant. 481. *Shrubby Goldylocks with narrow leaves and downy branches.* Conyza Africana, tenuifolia, ſubfruteſcens, flore aureo. Hort. Elth. 104. tab. 68. *Narrow-leaved, African, ſhrubby Fleabane, with a golden flower.*

The firſt ſort grows naturally in Germany, and alſo in France and Italy; this hath a perennial root; the ſtalks riſe two feet and a half high, are round, ſtiff, and cloſely garniſhed with long, narrow, ſmooth leaves, which come out without any order, of a pale green colour; the upper part of the ſtalk divides into many ſlender foot-ſtalks, each ſuſtaining a ſingle head of flowers, which are compoſed of many hermaphrodite florets, contained in one common empalement, having very narrow ſcales. The flowers are of a bright yellow, and ſtand diſpoſed on the top of the ſtalk, in form of an umbel. Theſe appear in July; and in favourable ſeaſons are ſucceeded by ſeeds, which ripen in September, ſoon after which the ſtalks decay to the root, and new ones ariſe the following ſpring.

This plant is generally propagated by parting of the roots, that being the moſt expeditious method; for the ſeedling plants do not flower till the ſecond or third year. The beſt time to remove the plants and part their roots, is ſoon after the ſtalks decay in autumn, that the plants may get freſh roots before winter. It delights in a dry looſe ſoil, in which it will live in the open air, and propagate by its roots very faſt; but in ſtrong wet land, the roots often rot in winter.

The ſecond ſort grows naturally in Siberia, from whence the ſeeds were ſent to Peterſburgh, part of which I received from the late Dr. Amman, who was profeſſor of botany in that univerſity. This plant hath a perennial creeping root, which ſpreads on every ſide to a conſiderable diſtance, ſending up many erect ſtalks, garniſhed with flat ſpear-ſhaped leaves, ending in points; theſe are rough, and have three longitudinal veins; the upper part of the ſtalks branch out, and form looſe panicles of yellow flowers, which are larger than thoſe of the former ſort. This flowers in June and July, and the ſeeds ripen in autumn.

It propagates too faſt by its creeping roots to be admitted into the flower-garden, for the roots will often extend two or three feet every way in the compaſs of one year, ſo that they will interfere with the neighbouring flowers; but as the plants will grow in any ſoil or ſituation, ſo a few roots may be planted on the ſide of extenſive rural walks round the borders of fields, where they will require no care, and their flowers will make a good appearance, and continue long in beauty.

The third ſort grows naturally at the Cape of Good Hope. This riſes with a ligneous ſtalk about a foot high, dividing into many ſmall branches, which are garniſhed with narrow leaves, of a deep green, coming out on every ſide without order; the back part of each leaf hath a ſmall ſhort appendix, which runs along the ſtalks. The flowers are produced at the end of the branches, on ſlender naked foot-ſtalks; theſe are of a pale yellow, and ſhaped like thoſe of the former ſorts, but are larger. This plant flowers great part of the year, for which it is chiefly eſteemed; the ſeeds ripen very well in autumn, which if ſown on a common border of light earth in the ſpring, the plants will come up, and may be tranſplanted into pots, to be removed into ſhelter in winter, for theſe plants will not live through the winter in the open air in England.

The moſt expeditious method of propagating this plant is by cuttings, which, if planted in a common border in any of the ſummer months, and covered with hand-glaſſes, will eaſily take root, provided they are ſhaded from the ſun and duly watered: when theſe have gotten good roots they ſhould be carefully taken up, and each planted in a ſeparate pot, filled with light earth, placing them in the ſhade till they have taken new root; then they may be expoſed with other hardy exotic plants till autumn, when they muſt be removed into the green-houſe during the winter ſeaſon; they ſhould enjoy a large ſhare of free air in mild weather, for they only require protection from froſt, ſo muſt not be too tenderly treated.

The fourth ſort is a native of the Cape of Good Hope, from whence I received the ſeeds; this is a leſs plant than the former, it hath a ſhrubby ſtalk, branching out in the ſame manner; the leaves are ſhorter, and a little hairy; the flowers are not half ſo large, of a pale ſulphur colour, and nod on one ſide before they are blown. This alſo flowers great part of the year, and ripens ſeeds very well; but this is generally propagated in the ſame manner as the former, and the plants require the ſame treatment.

The fifth ſort is alſo a native of the ſame country as the two former; this hath a low ſhrubby ſtalk, which branches out on every ſide, very narrow, ſhort, rough, and reflexed; the flowers ſtand ſingle on the top of naked foot-ſtalks, which ariſe from the upper part of the branches; theſe flowers are larger than thoſe of the laſt, and ſtand erect. This plant requires the ſame treatment as the two former, and is propagated by cuttings in the ſame manner.

CHRYSOPHYLLUM. Lin. Gen. Plant. 233. Cainito. Plum. Nov. Gen. 9. tab. 9. The Star Apple.

The Characters are,

The empalement is permanent, and conſiſts of five ſmall, roundiſh, concave petals; the flower is compoſed of five petals, which ſpread open, and are cut in the middle into two parts; it hath five ſtamina placed alternate to the ſegments of the petals, terminated by heart-ſhaped ſummits: the oval germen is ſituated in the center, ſupporting

ing a ſhort ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a large, oval, fleſhy fruit, incloſing three or four flat ſeeds, having hard ſhells.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Chrysophyllum (*Cainito*) foliis ovatis, parallele ſtriatis ſubtus, tomentoſo-nitidis. Jacq. Amer. 15. *Chryſophyllum with oval leaves, with parallel veins and neat woolly leaves on their under ſide.* Cainito folio ſubtus aureo, fructu olivæ formi. Plum. Nov. Gen. 10. *The Damſon-tree.*

2. Chrysophyllum (*Glabrum*) foliis utrinque glaberrimis. Jacq. Amer. 15. *Chryſophyllum with very ſmooth leaves.* Cainito folio ſubtus aureo, fructu maliformi. Plum. Nov. Gen. 10. *The Star Apple.*

Theſe trees grow naturally in the Weſt-Indies, where the firſt ſort riſes from twenty to thirty feet high, dividing into many branches, garniſhed with oval leaves, ſmooth above, and of a gold colour on their under ſide; the flowers come out from the ſide of the branches, at the ſetting on of the leaves, in round cluſters, which are ſucceeded by oval, ſmooth, pulpy fruit, incloſing three or four hard flat ſeeds.

The ſecond ſort riſes with an upright trunk to the height of thirty or forty feet, dividing into many ſlender branches, garniſhed with ſpear-ſhaped leaves, coming out without order; from the wings of the leaves, and alſo at the extremity of the branches, the flowers are produced in bunches, which are ſucceeded by round pulpy fruit the ſize of a Golden Pippin, containing many flat hard ſeeds.

The fruit of both theſe trees is very rough and aſtringent at firſt, but by lying ſome time after they are gathered, they become mellow, like the Medlar. The timber of both theſe trees is uſed in buildings, and for ſhingles to cover houſes.

Theſe plants are preſerved in ſeveral curious gardens for the beauty of their leaves, eſpecially the firſt ſort, whoſe under ſides ſhine like ſattin, the upper ſides are of a deep green. The leaves continue all the year, ſo make a very pretty appearance in the ſtove at all ſeaſons.

Theſe trees, being natives of the warmeſt parts of the world, cannot be preſerved in this country, without being kept in the warmeſt ſtoves; and ſhould always remain in a hot-bed of tanners bark, otherwiſe they will make but little progreſs. They are propagated by ſeeds, which muſt be procured from the places of their growth, for they do not produce fruit in Europe. Theſe ſeeds muſt be freſh, otherwiſe they will not grow; and if they are ſent over in ſand, it will preſerve them from drying too much; when the ſeeds arrive, they muſt be ſown as ſoon as poſſible in ſmall pots filled with light freſh earth, and plunged into a good hot-bed of tanners bark. If the ſeeds are good, and the bed in a proper temperature of warmth, the plants will appear in five or ſix weeks; and in about two months after, will be ſtrong enough to tranſplant; in doing of which, the plants, with all the earth, ſhould be ſhaken out of the pots very carefully, and ſeparated with their roots entire, and each planted into a ſingle ſmall pot filled with freſh rich earth, and plunged again into a hot-bed of tanners bark, watering and ſhading them until they have taken freſh root. If the hot-bed in which theſe plants are plunged, is from time to time ſtirred, and a little freſh tan added to it, to renew the heat when it declines, the plants will make good progreſs, and in three or four months will be near a foot high, and may then be ſhifted into pots a ſmall ſize larger than thoſe they before were in. If theſe plants are conſtantly kept in a warm bed in the ſtove, and ſhifted twice a year, to renew the earth to their roots, they will thrive very faſt, and put out their ſide branches, ſo as to make a handſome appearance in the ſtove, with other curious plants of the ſame country; for though they do not produce either flowers or fruit, yet as they keep their leaves through the year, which are ſo very beautiful, they deſerve a place in the ſtove, better than moſt other plants. The chief care they require, is to keep them conſtantly in a proper degree of heat, and never to put them into too large pots; and in winter they ſhould not have too much water, about twice a week will be often enough to water them; and in the depth of winter, they ſhould not have much at each time.

Theſe trees are frequently propagated in the Weſt-Indies, by planting of their branches (as I have been informed by perſons of credit;) but I have not heard of their being propagated in England by that method.

CHRYSOSPLENIUM. Lin. Gen. Plant. 493. [χρυσοσπλήνιον, of χρυσὸς, Gold, and σπλὴν, the ſpleen; q. d. a plant, the flowers of which are of a golden colour, and good againſt diſeaſes of the ſpleen.] Golden Saxifrage.

The Characters are,

The empalement is divided into four or five parts, which ſpread open, are coloured, and permanent. The flower hath no petals, but eight or ten ſtamina, which are ſhort, erect, and ſtand oppoſite to the angles of the empalement, terminated by ſingle ſummits: the germen is immerſed in the empalement, ſupporting two ſhort ſtyles, crowned by obtuſe ſtigma. The germen afterward becomes a capſule with two beaks, opening with two valves, and filled with ſmall ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's tenth claſs, intitled Decandria Digynia, the flowers having ten ſtamina and two ſtyles.

The Species are,

1. Chrysosplenium (*Alternifolium*) foliis alternis. Flor. Suec. 317. *Golden Saxifrage with alternate leaves.* Saxifraga aurea foliis pediculis oblongis inſidentibus. Raii Syn. Hiſt. 206. *Golden Saxifrage with leaves growing upon long foot-ſtalks.*

2. Chrysosplenium (*Oppoſitifolium*) foliis oppoſitis. Sauv. Monſp. 128. *Golden Saxifrage with oppoſite leaves.* Chryſoſplenium foliis amplioribus auriculatis. Tourn. Inſt. 146. *Golden Saxifrage with larger eared leaves.*

Theſe two plants are found growing wild in many parts of England, upon marſhy ſoils and bogs, as alſo in moiſt ſhady woods, and are ſeldom propagated in gardens; where, if any perſon has curioſity to cultivate them, they muſt be planted in very moiſt ſhady places, otherwiſe they will not thrive. They flower in March and April.

CIBOULS, or CHIBOULS. See Cepa.

CICER. Lin. Gen. Plant. 783. Tourn. Inſt. R. H. tab. 210. [This plant is called Cicer, of Κίκυς, ſtrength, becauſe it is ſaid to ſtrengthen: it is alſo called Arietaria, becauſe the ſeeds of it reſemble the head of a ram.] Cicer, or Chich Peaſe.

The Characters are,

The empalement of the flower is cut into five ſegments, four of which lie upon the ſtandard; the two middle, which are the longeſt, are joined, the other is under the keel. The flower is of the butterfly kind; the ſtandard is large, roundiſh, and plain; the wings are much ſhorter and obtuſe, the keel is ſhorter than the wings, and is ſharp-pointed. It hath ten ſtamina, nine of them are joined, and the tenth is ſeparate, terminated by ſingle ſummits. It hath an oval germen ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a turgid ſwelling pod of a rhomboidal figure, incloſing two roundiſh ſeeds, with a protuberance on their ſide.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, from the flower having ten ſtamina joined in two bodies.

There is but one Species of this genus, viz.

Cicer (*Arietinum*) foliolis ſerratis. Hort. Cliff. 370. *Chich Peaſe with ſawed leaves.* Cicer ſativum. C. B. P. 347. *Garden Chich Peaſe.*

There is a variety of this with a red ſeed, which differs from it in nothing but the colour.

It is much cultivated in Spain, being one of the ingredients in their olios, and is there called Garavance; it is alſo cultivated in France, but in England it is rarely ſown.

This plant is annual, ſhooting out ſeveral hairy ſtalks from the root, which are about two feet long; garniſhed with long winged leaves of a grayiſh colour, compoſed of ſeven or nine pair of ſmall roundiſh leaves (or lobes) terminated by an odd one, which are ſawed on their edges. From the ſide of the branches come out the flowers, ſometimes one, at other times two together. They are ſhaped like thoſe of Peaſe, but are much ſmaller and white, ſtanding on long foot-ſtalks; theſe are ſucceeded by ſhort hairy pods, including two ſeeds in each, which are the ſize of common Peaſe, but have a little knob or protuberance on one ſide.

The ſeeds of this plant may be ſown in the ſpring, in the ſame manner as Peaſe, making drills with a hoe, about an inch and a half deep, in which the ſeeds ſhould be ſown at about two inches aſunder, then with a rake draw the earth into the drill to cover the ſeeds. The drills ſhould be made at three feet diſtance from each other, that there may be room for their branches to ſpread, when the plants are fully grown, as alſo to hoe the ground between them, to keep it clean from weeds, which is all the culture theſe plants require.

This plant flowers in June, and the ſeeds ripen in Auguſt; but unleſs the ſeaſon proves warm and dry, the plants decay in this country before the ſeeds are ripe.

CICHORIUM. Lin. Gen. Plant. 825. Tourn. Inſt. R. H. tab. 272. [κιχώριον, or κιχόρειον, of κιχέω, to find, becauſe found every where in walking.] Succory.

The CHARACTERS are,

The flower hath a common ſcaly empalement, which at firſt is cylindrical, but is afterward expanded; the ſcales are narrow, ſpear-ſhaped, and equal. The flower is compoſed of many hermaphrodite florets, which are plain, uniform, and ſtand circularly, each having one petal, which is tongue-ſhaped, and cut into five ſegments. They have five ſhort hairy ſtamina, terminated by five-cornered cylindrical ſummits. The germen is ſituated under the petal, ſupporting a ſlender ſtyle, crowned by two turning ſtigmas: the germen afterward becomes a ſingle ſeed, incloſed with a down, and ſhut up in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia æqualis. The plants of this ſection have only hermaphrodite fruitful florets.

The SPECIES are,

1. CICHORIUM (*Intybus*) floribus geminis ſeſſilibus, foliis runcinatis. Flor. Suec. 650. *Succory with two flowers ſitting cloſe to the ſtalk.* Cichorium ſylveſtre ſive officinarum. C. B. P. 126. *Wild Succory.*
2. CICHORIUM (*Spinoſum*) caule dichotomo ſpinoſo floribus axillaribus ſeſſilibus. Hort. Cliff. 388. *Succory with a prickly forked ſtalk.* Cichorium ſpinoſum. C. B. P. 126. *Prickly Succory.*
3. CICHORIUM (*Endivia*) floribus ſolitariis pedunculatis, foliis integris, crenatis. Hort. Cliff. 389. *Succory with ſingle flowers on foot-ſtalks, and entire crenated leaves.* Cichorium latifolium, ſive endivia vulgaris. C. B. P. 125. *Broad-leaved Succory, or common Endive.*
4. CICHORIUM (*Criſpum*) floribus ſolitariis pedunculatis, foliis fimbriatis, criſpis. *Succory with ſingle flowers on foot-ſtalks, and fringed curled leaves.* Endivia criſpa. C. B. P. 125. *Curled Endive.*

The firſt ſort grows naturally by the ſides of roads and in ſhady lanes, in many parts of England: this has been ſuppoſed to be no other way differing from the garden Succory, but by the latter being cultivated in gardens; indeed, moſt of the writers on botany, have confounded the two ſorts together; for the Garden Succory which is deſcribed in moſt of the old books, I take to be the broad-leaved Endive, which is the third ſort here enumerated, for I have many years cultivated both ſorts in the garden, without finding either of them alter. There is an eſſential difference between theſe, for the wild Succory hath a perennial creeping root, whereas the other is at moſt but a biennial plant; and if the ſeeds of the latter are ſown in the ſpring, the plants will flower and produce ſeeds the ſame year, and periſh in autumn, ſo that it may rather be called annual. The wild Succory ſends out from the roots long leaves, which are jagged to the midrib, each ſegment ending in a point; from between theſe ariſe the ſtalks, which grow from three to four feet high, garniſhed with leaves, ſhaped like thoſe at the bottom, but are ſmaller, and embrace the ſtalks at their baſe. Theſe branch out above into ſeveral ſmaller ſtalks, which have the ſame leaves, but ſmaller and leſs jagged; the flowers are produced from the ſide of the ſtalks, which are of a fine blue colour; theſe are ſucceeded by oblong ſeeds, incloſed in a down. It flowers in June and July, and the ſeeds ripen in September.

The ſecond ſort grows naturally on the ſea-coaſts in Sicily and the iſlands of the Archipelago. This ſends out from the root many long leaves, which are indented on their edges, ſpreading flat on the ground; from between theſe ariſe the ſtalks, which have very few leaves, and thoſe ſmall and entire: the ſtalks are divided in forks upward, from between theſe come out the flowers, which are of a pale blue, and are ſucceeded by ſeeds ſhaped like thoſe of the common ſort; the ends of the ſmaller branches are terminated by ſtar-like ſpines, which are very ſharp. The plant is biennial with us in England, and in cold winters is frequently killed. It flowers and ſeeds about the ſame time with the former ſort, and may be treated in the ſame way as the Endive.

The broad leaved Succory or Endive, differs from the wild ſorts in its duration, the root always periſhing after it has ripened ſeeds: the leaves are broader, rounder at the top, and not laciniated on the ſides as the leaves of the wild; the branches are more horizontal, and the ſtalks never riſe ſo high.

This ſort is not much cultivated in the Engliſh gardens at preſent, for the curled Endive being tenderer, and not ſo bitter, is generally preferred to it. The broad-leaved and curled Endive has been ſuppoſed to be only varieties from each other, which hath accidentally been produced by culture; but from having cultivated both near forty years, I could never find that they ever altered, otherwiſe than by the curled ſort coming more or leſs curled; the leaves of this ſort have only a few ſlight indentures on their edges, and the ſtalks grow more erect, having but few leaves upon them. This, when blanched, has a bitter taſte, which has occaſioned its being generally neglected in England, but in Italy it is ſtill cultivated in their gardens.

All the ſorts of Succory are eſteemed aperitive and diuretic, opening obſtructions of the liver, and good for the jaundice; it provokes urine, and cleanſes the urinary paſſages of ſlimy humours, which may ſtop their paſſage.

The curled Endive is now much cultivated in the Engliſh gardens, being one of the principal ingredients in the ſallads of autumn and winter, for which purpoſe it is continued as long as the ſeaſons will permit. I ſhall therefore give directions for the managing of this plant, ſo as to have it in perfection during the autumn and winter months.

The firſt ſeaſon for ſowing of theſe ſeeds is in May, for thoſe which are ſown earlier in the year, generally run up to ſeed, before they have arrived to a proper ſize for blanching; and it frequently happens, that the ſeeds ſown in May in the rich ground near London, will run to ſeeds the ſame autumn; but in ſituations which are colder, they are not ſo apt to run up, therefore there ſhould be ſome ſeeds ſown about the middle or latter end of that month. The ſecond ſowing ſhould be about the middle of June, and the laſt time in the middle of July. From theſe three different crops, there will be a ſupply for the table during the whole ſeaſon; for there will be plants of each ſowing, very different in their growth, ſo that there will be three different crops from the ſame beds.

When the plants come up they muſt be kept clean from weeds, and in dry weather duly watered, to keep them growing till they are fit to tranſplant, when there ſhould be an open ſpot of rich ground prepared to receive the plants, in ſize proportionable to the quantity intended. When the ground is well dug and levelled, if it ſhould be very dry, it muſt be well watered to prepare it to receive the plants; then the plants ſhould be drawn up from the ſeed-bed carefully, ſo as not to break their roots, drawing out all the largeſt plants, leaving the ſmall ones to get more ſtrength; which, when they have room to grow, by taking away the large ones, they will ſoon do. As the plants are drawn up, they ſhould be placed with their roots even, all the ſame way, and every handful as they are drawn, ſhould have the tops of their leaves ſhortened, to make them of equal length: this will render the planting of them much eaſier, than when the plants are promiſcuouſly mixed, heads and tails: then the ground ſhould be marked out in rows at one foot aſunder, and the plants ſet ten inches diſtant in the rows, cloſing the earth well to their roots, and let them be well watered; and repeat this every other evening, till the plants have taken good root, after which they muſt be kept clean from weeds.

When the plants of the ſeed-bed have been thus thinned, they ſhould be well cleaned from weeds and watered, which will encourage the growth of the remaining plants, ſo that in ten days or a fortnight after, there may be another thinning made of the plants, which ſhould be tranſplanted in the ſame manner. And at about the ſame diſtance of time, the third and laſt drawing of plants may be tranſplanted.

Thoſe plants which were the firſt tranſplanted, will be fit to blanch by the latter end of July at fartheſt; and if they are properly managed, in three weeks or a month, they will be ſufficiently blanched for uſe, which will be as ſoon as theſe ſallads are commonly required; for during the continuance of good Cos Lettuce, few perſons care for Endive in their ſallads; nor, indeed, is it ſo proper for warm weather. If any of the plants ſhould put out flower-ſtems, they ſhould be immediately pulled up and carried away, being good for nothing, ſo ſhould not be left to incommode the neighbouring plants. As the quantity of roots neceſſary for the ſupply of a middling family is not very great, ſo there ſhould not be too many plants tied up to blanch at the ſame time, therefore the largeſt ſhould be firſt tied, and in a week after thoſe of the next ſize; ſo that there may be three different times of blanching the plants, on the ſame ſpot of ground. But as in ſome large families there is a great conſumption of this herb for ſoups, ſo the quantities of plants ſhould be proportionably greater, at each time of planting and blanching. The manner of blanching is the next thing to be treated of, therefore in order to this you ſhould provide a parcel of ſmall Oſier twigs (or baſs mat) to tie up ſome of the largeſt heads to blanch; which ſhould be done in a dry afternoon, when there is neither dew nor rain to moiſten the leaves in the middle of the plants, which would occaſion their rotting ſoon after their being tied up. The manner of doing it is as follows, viz. You muſt firſt gather up all the inner leaves of the plant in a regular order, into one hand, and then take up thoſe on the outſide that are ſound, pulling off and throwing away, all the rotten and decayed leaves which lie next the ground; obſerving to place the outſide leaves all round the middle ones, as near as poſſible to the natural order of their growth, ſo as not to croſs each other: then having got the whole plant cloſe up in your hand, tie it up with the twig, baſs, &c. at about two inches below the top, very cloſe; and about a week after go over the plants again, and give them another tie about the middle of the plant, to prevent the heart leaves from burſting out on one ſide; which they are ſubject to do, as the plants grow, if not prevented this way.

In doing of this you need only tie up the largeſt plants firſt, and ſo go over the piece once a week, as the plants increaſe in their growth; by which means you will continue the crop longer, than if they were all tied up at one time: for when they are quite blanched, which will be in three weeks or a month after tying, they will not hold ſound and good above ten days or a fortnight, eſpecially if the ſeaſon proves wet: therefore it is that I would adviſe to ſow at three or four different ſeaſons, that you may have a ſupply as long as the weather will permit. But in order to this, you muſt tranſplant all the plants of the laſt ſowing under warm walls, pales, or hedges, to ſcreen the plants from froſt; and if the winter ſhould prove very ſharp, you ſhould cover them with ſome Peaſe haulm, or ſuch other light covering, which ſhould be conſtantly taken off in mild weather: theſe borders ſhould alſo be as dry as poſſible, for theſe plants are very ſubject to rot, if planted in a moiſt ſoil in winter.

Although I before directed the tying up of the plants to blanch them, yet this is only to be underſtood for the two firſt ſowings; for after October, when the nights begin to be froſty, thoſe plants which are ſo far above ground will be liable to be much prejudiced thereby, eſpecially if they are not covered in froſty weather; therefore the beſt method is, to take up your plants of the latter ſowings in a very dry day, and with a large flat-pointed dibble, plant them into the ſides of trenches of earth, which ſhould be laid very upright, planting them ſideways, on the ſouth ſide of the trenches, towards the ſun, with the tops of the plants only out of the ground, ſo that the haſty rains may run off, and the plants be kept dry, and ſecured from froſts.

The plants thus planted, will be blanched fit for uſe in about a month or five weeks time, after which it will not keep good more than three weeks, before it will decay; you ſhould therefore continue planting ſome freſh ones into trenches every fortnight or three weeks, that you may have a ſupply for the table; and thoſe which were laſt tranſplanted out of the ſeed beds, ſhould be preſerved till February, before they are planted to blanch; ſo that from this you may be ſupplied until the beginning of April, or later: for at this laſt planting into the trenches, it will keep longer than in winter, the days growing longer; and the ſun, advancing with more ſtrength, dries up the moiſture much ſooner than in winter, which will prevent the rotting of theſe plants; but if the weather ſhould prove froſty, theſe latter plantations of Endive ſhould be covered with mats and ſtraw to preſerve it, otherwiſe the froſt will deſtroy it, but the coverings muſt always be taken off when the weather is favourable.

When your Endive is blanched enough for uſe, you muſt dig it up with a ſpade; and after having cleared it from all the outſide green and decayed leaves, you ſhould waſh it well in two or three different waters to clear it the better from ſlugs, and other vermin, which commonly ſhelter themſelves amongſt the leaves thereof, and then you may ſerve it up to the table with other ſallading.

But in order to have a ſupply of good ſeeds for the next ſeaſon, you muſt look over thoſe borders where the laſt crop was tranſplanted, before you put them into the trenches to blanch; and make choice of ſome of the largeſt, ſoundeſt, and moſt curled plants, in number according to the quantity of ſeeds required: for a ſmall family, a dozen of good plants will produce ſeeds enough; and for a large, two dozen or thirty plants.

Theſe ſhould be taken up and tranſplanted under a hedge or pale, at about eighteen inches diſtance, in one row about ten inches from the hedge, &c. This work ſhould be done in the beginning of March, if the ſeaſon is mild, otherwiſe it may be deferred a fortnight longer. When the flower-ſtems begin to advance, they ſhould be ſupported with a packthread, which ſhould be faſtened to nails driven into the pale, or to the ſtakes of the hedge, and run along before the ſtems, to draw them upright cloſe to the hedge or pale, otherwiſe they will be liable to break with the ſtrong winds. Obſerve alſo to keep them clear from weeds, and about the beginning of July your ſeeds will begin to ripen; therefore, as ſoon as you find the ſeeds are quite ripe, you muſt cut off the ſtalks, and expoſe them to the ſun upon a coarſe cloth to dry; and then beat out the ſeeds, which muſt be dried, and put up in bags of paper, and preſerved for uſe in ſome dry place. But I would here caution you, not to wait for all the ſeeds ripening upon the ſame plant; for if ſo, all the firſt ripe and beſt of the ſeeds will ſcatter and be loſt before the other are near ripe; ſo great a difference is there in the ſeeds of the ſame plant being ripe.

The wild Succory (of which there are ſome varieties in the colour of the flowers) is ſeldom propagated in gardens; it growing wild in unfrequented lanes and dunghills in divers parts of England, where the herb women gather it, and ſupply the markets for medicinal uſe.

CICUTA properly ſignifies an hollow intercepted between two knots, of the ſtalks or reeds of which the ſhepherds uſed to make their pipes, as Virgil ſings;

Eſt mihi diſparibus ſeptem compacta Cicutis
Fiſtula——

CICUTA. Lin. Gen. Plant. 316. Sium. Raii Syn. 212. Water Hemlock.

The Characters are,

It is a plant with an umbellated flower; the principal umbel is compoſed of ſeveral ſmaller (called rays;) theſe are equal, roundiſh, and briſtly: the great umbel hath no involucrum, but the ſmaller have, which are compoſed of many ſhort leaves. The flowers have each five oval petals nearly equal, which turn inward; they have five hairy ſtamina, which are longer than the petals, terminated by ſingle ſummits. The germen is ſituated below the flower, ſupporting two ſlender ſtyles, which are permanent and longer than the petals, crowned by ſtigmas in form of a head. The germen afterward becomes a roundiſh channelled fruit dividing into two parts, containing two oval ſeeds, plain on one ſide and convex on the other.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs of plants, intitled Pentandria Digynia, the flower having five ſtamina and two ſtyles. The title of this genus has been generally applied to the common Hemlock, which grows naturally on the banks by highways, in moſt parts of England. But to that plant Dr. Linnæus has applied the old title of Conium, and added this title to the poiſonous Water Hemlock deſcribed by Webfer.

The Species are,

1. Cicuta (*Viroſa*) umbellis oppoſitis foliis, petiolis marginatis. Lin. Sp. Plant. 255. *Hemlock with umbels oppoſite to the leaves, and obtuſe marginated foot-ſtalks.* Sium erucæ folio. C. B. P. 154. *Sium with a Rocket leaf.* Cicuta aquatica Geſneri. J. B. 111. 2. p. 175. *Water Hemlock of Geſner.*
2. Cicuta (*Maculata*) foliorum ſerraturis mucronatis, petiolis membranaceis, apice bilobis. Lin. Sp. Plant. 256. *Hemlock with pointed ſerratures to the leaves, and membranaceous foot-ſtalks ending in two lobes.* Angelica Virginiana foliis acutioribus, ſemine ſtriato minore, cumini ſapore & odore. Mor. Hiſt. 3. p. 281. *Virginia Angelica with pointed leaves, and a ſmall channelled ſeed, having the taſte and ſmell of Cumin.*
3. Cicuta (*Bulbifera*) ramis bulbiferis. Lin. Sp. 367. *Hemlock, whoſe branches bear bulbs.* Ammi foliorum lacinulis capillaribus, caule angulato. Flor. Virg. 31.

The firſt ſort grows naturally in ſtanding waters in many parts of England, ſo is never propagated in gardens; for unleſs there is a conſiderable depth of ſtanding water for the plants to root in, they will not grow. I have ſeveral times tranſplanted theſe plants into ponds, where they have grown one ſummer, but have not continued through the winter.

It grows near four feet high, with a branching hollow ſtalk, garniſhed with winged leaves. The ſtalks are terminated by umbels of yellowiſh flowers, which are ſucceeded by ſmall channelled ſeeds like thoſe of Parſley. It flowers in June and July, and the ſeeds ripen in autumn.

The ſecond ſort grows naturally in North America, from whence the ſeeds have been brought to England, where the plants are preſerved in botanic gardens for the ſake of variety. This is propagated by ſeeds, which ſhould be ſown in autumn in a ſhady border, where the plants will come up in the ſpring, and require no other care but to keep them clean.

The third ſort is a native of North America. This is ſometimes preſerved in botanic gardens for variety, but being a plant of no great beauty or uſe, is ſeldom allowed a place in other gardens. It is propagated by ſeeds, which ſhould be ſown in autumn, and the plants afterward treated as thoſe of the ſecond ſort.

CICUTARIA. See Ligusticum.

CINARA. See Cynara.

CINERARIA, Sea Ragwort.

The Characters are,

It has a ſimple empalement, compoſed of many ſmall equal leaves. The flower is radiated. The diſk is compoſed of many hermaphrodite florets, which are funnel-ſhaped, cut into five ſegments at the top; theſe have five ſlender ſtamina, crowned by cylindrical ſummits, and an oblong germen, ſupporting a very ſlender ſtyle, crowned by two erect ſtigmas. The germen afterward becomes a narrow four-cornered ſeed, covered with downy hairs. The female florets which compoſe the rays are tongue-ſhaped, indented at their points; theſe have an oblong germen with two ſtyles, and have ſeeds like the hermaphrodite florets, which are included in the empalement.

This genus of plants is ranged in the ſecond order of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia ſuperflua, the flowers being compoſed of hermaphrodite and female florets, which are both fruitful.

The Species are,

1. Cineraria (*Geifolia*) pedunculis ramoſis, foliis reniformibus ſuborbiculatis ſublobatis dentatis petiolatis. Lin. Sp. 1242. *Ragwort with branching foot-ſtalks, kidney-ſhaped, orbicular, indented leaves upon foot-ſtalks.* Jacobæa Africana, hederæ terreſtris folio, repens. Hort. Amſt. 2. p. 145.
2. Cineraria (*Maritima*) floribus paniculatis, foliis pinnatifidis tomentoſis, laciniis ſinuatis, caule fruteſcente. Lin. Sp. 1244. *Sea Ragwort with a ſhrubby ſtalk, woolly wing-pointed leaves, and flowers growing in panicles.* Jacobæa maritima. C. B. P. 131. *Sea Ragwort.*
3. Cineraria (*Amelloides*) pedunculis unifloris, foliis ovatis oppoſitis, caule ſuffruticoſo. Lin. Sp. 1245. *Ragwort with an under ſhrub ſtalk, oval leaves placed oppoſite, and foot-ſtalks with one flower.* After caule ramoſo ſcabro perenne, foliis ovatis ſeſſilibus, pedunculis nudis unifloris. Fig. pl.
4. Cineraria (*Othonnites*) pedunculis unifloris, foliis oblongis indiviſis ſubdentatis petiolatis alternis nudis. Lin. Sp. 1244. *Ragwort with oblong undivided leaves ſlightly indented, and foot-ſtalks with one flower.* Jacobæa Africana fruteſcens, craſſis & ſucculentis foliis. Hort. Amſt. 2. p. 147.
5. Cineraria (*Tomentoſa*) foliis pinnato-ſinuatis dentatis ſubtus tomentoſis, floribus paniculatis, caule fruteſcente. *Ragwort with ſinuated, wing-ſhaped, indented leaves, downy on their under ſide, flowers in panicles, and a ſhrubby ſtalk.* Jacobæa maritima latifolia. C. B. P. 69.

There are ſeveral other ſpecies of this genus than are here enumerated, but being plants of little uſe or beauty are omitted, as they are rarely cultivated in gardens.

The firſt ſort grows naturally at the Cape of Good Hope. The root of this is compoſed of many ſmall fibres; the ſtalks are weak, ſo trail on the ground, if they are not ſupported; but if they are will riſe four feet high, dividing into many branches, garniſhed with roundiſh kidney-ſhaped leaves, crenated on their edges; the flowers are produced at the extremity of the branches in ſmall cluſters; they are yellow, and in ſhape like thoſe of the common Ragwort, which are ſucceeded by ſeeds, crowned with down.

This ſort is eaſily propagated by cuttings, which, if planted in a ſhady border during the ſummer months, and duly watered, will put out roots in a month or five weeks; ſoon after which it will be proper to tranſplant them into pots, becauſe their roots are very apt to ſpread in the full ground; ſo when the plants are taken up, many of their roots are torn off, whereby the plants are endangered. This is alſo often the caſe of the plants in pots. When they are not often removed, their roots will ſhoot through the holes in the bottom of the pots into the ground, and the plants will grow luxuriantly; but when the pots are removed, and thoſe roots torn off, the plants are often killed thereby. As this plant grows naturally at the Cape of Good Hope, it is too tender to live through the winters in England in the open air; yet if it is nurſed tenderly, it is very apt to draw up weak, and thereby is deſtroyed; therefore the ſureſt method to preſerve it, is to make young plants annually from cuttings, and to place them in a common hot-bed frame in winter, where they may enjoy the full air in mild weather, but be ſcreened from the froſt, and in ſummer place them abroad with other of the hardier ſorts of exotic plants.

The ſecond ſort grows naturally on the ſea-coaſts in ſome parts of England and Wales, in particular warm ſpots, but in the ſouth of France and Italy, it is very common. This hath many ligneous ſtalks, which riſe two or three feet high, dividing into many branches, which have a white downy bark, and are garniſhed with very woolly leaves ſix or eight inches long, deeply ſinuated, and jagged on their borders into many winged points; they are downy on both ſides. The ſtalks which ſupport the flowers are a foot or more in length, having two or three ſmall leaves on each, ſhaped like thoſe below, and are terminated by many yellow flowers growing in panicles, ſhaped like thoſe of common Ragwort; theſe appear in June, July, and Auguſt, and are ſucceeded by ſeeds, which ripen the beginning of October.

This ſort is alſo eaſily propagated by planting cuttings or ſlips of it on a ſhady border during the ſummer months, obſerving to water them duly. When theſe are well rooted, they ſhould be planted in a dry rubbiſhing ſoil, where they will reſiſt the cold of our ordinary winters very well, and continue many years; but in rich moiſt ground, the plants are often ſo very luxuriant in ſummer, as to be killed in winter when there is much froſt.

The third ſort grows naturally at the Cape of Good Hope. This hath branching ſtalks, which are ſhrubby, and riſe from two to three feet high, garniſhed with oval leaves placed oppoſite: the foot-ſtalks of the flowers are long, naked, and ſupport one blue flower at the top, whoſe rays are reflexed; theſe appear great part of the year, and thoſe which blow in ſummer are ſucceeded by compreſſed ſeeds crowned with down.

This may be propagated by ſowing the ſeeds on a bed of light earth the beginning of April, and when the plants are fit to remove, they ſhould be part of them planted in pots, that they may be ſheltered in winter under a hot-bed frame; the remainder may be planted cloſe to a warm wall in poor ground, where, if the winter proves favourable, they will live; but if theſe fail, thoſe in the frame will be ſecured. It may alſo be propagated by cuttings, in the ſame manner as the laſt mentioned.

The fourth ſort hath ſhrubby branching ſtalks, which riſe three or four feet high, garniſhed with oblong, thick, undivided leaves, of a glaucous colour. The flowers are produced on branching foot-ſtalks, ariſing toward the end of the branches; they are yellow, ſhaped like thoſe of the other ſorts, but are rarely ſucceeded by ſeeds in England. This is eaſily propagated by cuttings any time in ſummer: the plants, when rooted, muſt be planted in pots, that they may be removed into ſhelter in winter, for they will not live abroad in England. It grows naturally at the Cape of Good Hope.

The fifth ſort grows naturally on the ſea coaſts of Italy and Sicily. This has great reſemblance to the ſecond ſort, but the ſtalks are more woody, riſe higher, and do not branch ſo much. The leaves are broader, not ſo much ſinuated, and are of a black green colour on their upper ſide. The flowers are produced in ſmaller bunches on the top of the foot-ſtalks, and are like thoſe of the ſecond ſort, but are rarely ſucceeded by ſeeds in England, nor are the plants ſo hardy, therefore ſhould be ſheltered in winter. It is eaſily propagated by cuttings during the ſummer months, in the ſame way as the ſecond ſort.

CIRCEA. Lin. Gen. Plant. 24. Tourn. Inſt. R. H. 301. tab. 155. [It is ſaid to be ſo called from Circe, the famous enchantreſs, ſaid to have enchanted Ulyſſes and his companions. Boerhaave ſuppoſes it to be ſo called, becauſe the fruit of this plant takes hold of peoples cloaths, and by this means draws them to it, as the enchantreſs Circe was wont to do by her enchantments.] Enchanter's Nightſhade.

The Characters are,

The empalement of the flower is compoſed of two oval concave leaves: the flower hath two heart-ſhaped petals, which are equal and ſpread open; it hath two erect hairy ſtamina, terminated by roundiſh ſummits. The germen is ſituated under the flower, ſupporting a ſlender ſtyle, crowned by an obtuſe bordered ſtigma. The empalement afterward becomes a rough oval capſule with two cells opening lengthways, each containing a ſingle oblong ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, intitled Diandria Monogynia, the flower having two ſtamina and one ſtyle.

The Species are,

1. Circea (*Lutetiana*) caule erecto, racemis pluribus. Lin. Sp. Plant. 9. *Enchanter's Nightſhade, with an upright ſtalk and many ſpikes of flowers.* Circea lutetiana. Lob. Icon. 266. *Common Enchanter's Nightſhade.*
2. Circea (*Alpina*) caule adſcendente, racemo unico. Lin. Sp. Plant. 9. *Enchanter's Nightſhade, with an aſcending ſtalk and a ſingle ſpike.* Circea minima. Col. p. 2. 80. *Leaſt Enchanter's Nightſhade.*

The firſt ſort grows naturally in ſhady woods, and under hedges, in many parts of England. This plant hath a creeping root, by which it multiplies greatly. The ſtalks are upright, and riſe a foot and a half high, garniſhed with heart-ſhaped leaves placed oppoſite, upon very long foot-ſtalks: theſe are of a dark green on their upper ſide, but are pale on their under ſide. The ſtalks are terminated by looſe ſpikes of flowers, which are branched out into three or four ſmall ſpikes. The flowers are ſmall and white, having but two petals, oppoſite to which are ſituated the two ſtamina. After the flowers fall away, the empalement of the flower becomes a rough capſule, incloſing two oblong ſeeds.

The ſecond ſort grows at the foot of mountains in many parts of Germany. It alſo grows naturally in a wood near the Hague, from whence I brought it to England. This ſort ſeldom riſes more than ſix or eight inches high, with a ſlender ſtalk, garniſhed with leaves ſhaped like thoſe of the former ſort, but ſmaller, and are indented on their edges. The flowers are produced on ſingle looſe ſpikes at the top of the ſtalks, which are ſmaller than thoſe of the former ſort, but of the ſame form and colour. Theſe plants flower in June, and their ſeeds ripen in Auguſt; but they both multiply exceedingly by their creeping roots, ſo are ſeldom kept in gardens, unleſs for the ſake of variety.

If the roots are planted in any ſhady moiſt part of a garden, they will increaſe faſt enough without any care.

CIRCULATION of the ſap. See Sap.

CIRRI are thoſe fine ſtrings or fibres put out from the ſtalks of plants, by which ſome plants faſten themſelves to walls, pales, or trees, in order to their ſupport, as Ivy, &c.

CIRSIUM. See Carduus.

CISSAMPELOS. Lin. Gen. Plant. 993. Caapeba. Plum. Nov. Gen. 33. tab. 29.

The Characters are,

It is male and female in different plants; the male flowers have no empalement; they have four oval plain petals, and a wheel-ſhaped nectarium in the diſk, with four ſmall ſtamina joined together, crowned by plain ſummits. The female flowers have neither empalement or corolla; inſtead of petals, there is a large nectarium, whoſe membranes ſtand round the hairy oval germen, which afterward becomes a ſucculent berry, incloſing a ſingle ſeed.

This genus of plants is ranged in the twelfth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Monodelphia, the male and female flowers being on different plants, and the male flowers have four ſtamina, which are joined in one body.

The Species are,

1. Cissampelos (*Pariera*) foliis peltatis cordatis emarginatis. Lin. Sp. 1473. *Ciſſampelos with target heart-ſhaped leaves which are indented at their top.* Caapeba folio orbiculari, & umbilicato lævi. Plum. Nov. 33. *Caapeba with a round, ſmooth, umbilicated leaf.*
2. Cissampelos (*Caapeba*) foliis baſi petiolatis integris. Lin. Sp. 1473. *Ciſſampelos with leaves having foot-ſtalks, and entire at their baſe.* Caapeba folio orbiculari non umbilicato. Plum. Nov. Gen. 33. *Caapeba with a round leaf not umbilicated, called Velvet Leaf in America.*

Theſe plants grow naturally in the warmeſt parts of America, where they twiſt themſelves about the neighbouring ſhrubs, and riſe to the height of five or ſix feet. The firſt ſort hath round heart-ſhaped leaves, whoſe foot-ſtalks are ſet within the baſe of the leaf, reſembling an ancient target; theſe are hairy on their under ſide, and have pretty long ſlender foot-ſtalks. Toward the upper part of the ſtalks the flowers come out from the wings of the leaves; thoſe of the male plants grow in ſhort ſpikes or cluſters, and are of a pale herbaceous colour; but the female flowers are produced in long looſe racemi from the ſide of the ſtalks, and are ſucceeded by a ſingle pulpy berry incloſing a ſingle ſeed.

The ſecond ſort hath round heart-ſhaped leaves, which are extremely woolly and ſoft to the touch; theſe have their foot-ſtalks placed at the baſe between the two ears; the flowers of this come out in bunches from the ſide of the ſtalks, in the ſame manner as the firſt. The ſtalks and every part of the plant is covered with a ſoft woolly down.

The ſeeds of both theſe plants were ſent me from Jamaica, by the late Dr. Houſtoun, which ſucceeded in the Chelſea garden, where the plants produced their flowers for ſeveral years; and the fruit of the firſt ſort were produced, but theſe would not grow, though they ſeemed to be perfectly ripened; but the plants grew at ſome diſtance from the male, ſo were probably not impregnated.

Theſe plants are propagated by ſeeds, which ſhould be ſown upon a hot-bed in the ſpring; and the plants muſt afterward be treated in the ſame way as other tender exotics, keeping them conſtantly in the bark-ſtove, otherwiſe they will not live in this country.

The firſt ſort is ſuppoſed to be the Pareira, whoſe root has been ſo much eſteemed as a diuretic. But by a ſpecimen which I received from the late Dr. Houſtoun, under the title of Pariera, it ſhould rather be ranged under the genus of Smilax.

CISSUS, Wild Grape.

The Characters are,

It hath a ſmall many-leaved empalement, and four concave petals to the flower, with a large nectarium at the border of the germen, and four ſtamina the length of the corolla inſerted in the nectarium, crowned by roundiſh ſummits. The germen is four-cornered, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by an acute ſtigma. The cover of the flower afterward becomes a berry incloſing one roundiſh ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flowers having four ſtamina and one ſtyle.

The Species are,

1. Cissus (*Cordifolia*) foliis cordatis integerrimis. Lin. Sp. 170. *Wild Grape with entire heart-ſhaped leaves.* Vitis folio ſubrotundo, uva corymboſa cæruleo. Plum. Gen. 18.
2. Cissus (*Sicyoides*) foliis ovatis nudis ſetaceo ſerratis. Lin. Sp. 170. *Wild Grape with oval leaves which are ſawed.* Bryonia alba geniculato, violæ foliis, baccis e viridi-purpuraſcentibus. Sloan. Hiſt. Jam. 1. p. 106.
3. Cissus (*Acida*) foliis ternatis oblongis carnoſis inciſis. Lin. Sp. 170. *Wild Grape with trifoliate leaves, which are oblong, fleſhy, and cut on their edges.* Vitis trifolia minor corymboſa, acinis nigrioribus turbinatis. Plum. Sp. 18.
4. Cissus (*Trifoliata*) foliis ternatis ſubrotundis ſubdentatis. Lin. Sp. 170. *Wild Grape with roundiſh trifoliate leaves, which are ſlightly indented.* Bryonia alba triphylla maxima. Sloan. Hiſt. Jam. 1. p. 106.

Theſe plants all of them grow naturally in the iſland of Jamaica, and in ſome of the other iſlands in the warm parts of America, where they ſend out ſlender branches, having tendrils at their joints, by which they faſten to the neighbouring trees, buſhes, and any other ſupport, mounting to a conſiderable height. The firſt ſort produces bunches of fruit, which are frequently eaten by the negroes, but are chiefly food for birds and wild fowl, as indeed are moſt of the fruit of the other ſorts, as they all grow in the uncultivated parts.

The plants are preſerved in ſome of the European gardens, more for the ſake of variety, than for uſe or beauty, as they rarely produce either fruit or flowers in moderate climates. They are propagated either by laying their flexible branches down in pots of earth, where they will put out roots in four or five months, or by planting cuttings in pots filled with light earth, which ſhould be plunged into a moderate hot-bed of tanners bark, covering the pots cloſely with hand-glaſſes to exclude the outer air: the cuttings muſt be frequently refreſhed with water, but not too much given at each time. When theſe or the layers are well rooted, they ſhould be carefully taken up, and each planted in a ſmall pot filled with light earth, and plunged into the hot-bed of tan, where they ſhould conſtantly remain, being too tender to thrive in England, but with this care. Therefore they ſhould be ſhifted into larger pots when it is neceſſary, and their branches muſt be ſupported with ſtakes, to prevent them from trailing over the neighbouring plants; and in warm weather the plants ſhould have free air admitted to them daily. With this treatment they will thrive very well.

CISTUS. Lin. Gen. Plant. 598. Tourn. Inſt. R. H. 259. tab. 136. [It is ſo called from Κιστὸς, or Κισσὸς, *Gr.* Ivy, becauſe its ſmall ſeminal veſſel is incloſed in a ciſta, or little cheſt.] Rock-roſe.

The Characters are,

The flower hath a five-leaved empalement which is permanent, two of the middle alternate leaves being ſmaller than the other. The flower hath five large roundiſh petals which ſpread open; it hath a great number of hairy ſtamina, which are ſhorter than the petals, and are terminated by ſmall roundiſh ſummits. In the center is ſituated a roundiſh germen, ſupporting a ſingle ſtyle the length of the ſtamina, crowned by a plain orbicular ſtigma. The germen afterward becomes an oval cloſe capſule, having in ſome five, and others ten cells, filled with ſmall roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's thirteenth claſs, intitled Polyandria Monogynia, the flowers having many ſtamina and but one ſtyle.

The Species are,

1. Cistus (*Piloſus*) arboreſcens exſtipulatis foliis ovatis, petiolatis hirſutis. Lin. Sp. 736. *Tree Rock-roſe with oval leaves, whoſe foot-ſtalks are hairy.* Ciſtus mas major, folio rotundiore. J. B. 2. 2. *Greater male Ciſtus, or Rock-roſe, with a rounder leaf.*
2. Cistus (*Incanus*) arboreſcens exſtipulatis foliis ſpatulatis tomentoſis rugoſis, inferioribus baſi vaginantibus connatis. Hort. Cliff. 205. *Tree Rock-roſe with ſpatule-ſhaped, woolly, rough leaves, which are joined at their baſe.* Ciſtus mas 2 folio longiore incano. J. B. 2. 2.
3. Cistus (*Breviorifolius*) arboreſcens, foliis ovato-lanceolatis, baſi connatis, hirſutis, rugoſis, pedunculis florum longioribus. *Tree Rock-roſe with oval ſpear-ſhaped leaves, joined at their baſe, which are hairy and rough, and longer foot-ſtalks to the flowers.* Ciſtus mas folio breviore. C. B. P. 464.
4. Cistus (*Luſitanicus*) arboreſcens, foliis ovatis, obtuſis, villoſis, ſubtus nervoſis rugoſis, floribus amplioribus. *Tree Rock-roſe, with oval, obtuſe, hairy leaves, which are nervous and rough on their under ſide, and larger flowers.* Ciſtus mas Luſitanicus, folio ampliſſimo incano. Tourn. Inſt. 259.
5. Cistus (*Hiſpanicus*) arboreſcens villoſus, foliis lanceolatis, viridibus, baſi connatis, floribus ſeſſilibus, calycibus acutis. *Hairy-tree Rock-roſe with green ſpear-ſhaped leaves joined at their baſe, flowers ſittin cloſe, and ſharp-pointed empalements.*
6. Cistus (*Ladaniferus*) arboreſcens exſtipulatus, foliis lanceolatis, ſuprà lævibus, petiolis baſi coalitis vaginantibus. Hort. Cliff. 205. *Tree Rock-roſe with ſpear-ſhaped leaves, ſmooth on their upper ſide, and their foot-ſtalks joining like ſheaths.* Ciſtus ladanifera Hiſpanica incana. C. B. P. 467.
7. Cistus (*Albidus*) arboreſcens exſtipulatus foliis ovato-lanceolatis tomentoſis incanis, ſeſſilibus ſubtrinerviis. Sauv. Monſp. 150. *Tree Rock-roſe with oval, ſpear-ſhaped, woolly leaves, ſitting cloſe to the ſtalks.* Ciſtus mas folio oblongo incano. C. B. P. 464.
8. Cistus (*Salvifolius*) arboreſcens exſtipulatus, foliis ovatis petiolatis utrinque hirſutis. Hort. Cliff. 205. *Rock-roſe with oval hairy leaves, having foot-ſtalks.* Ciſtus fœmina, folio ſalviæ, ſupina humiſparſa. C. B. P. 466.
9. Cistus (*Creticus*) arboreſcens exſtipulatus, foliis ſpatulato-ovatis petiolatis enerviis ſcabris, calycinis lanceolatis. Lin. Sp. 738. *Tree Rock-roſe with oval ſpatule-ſhaped rough leaves without veins, having foot-ſtalks.* Ciſtus ladanifera Cretica flore purpureo. Tourn. Cor. 19. *Gum-bearing Ciſtus of Crete with a purple flower.*
10. Cistus (*Oleæfolius*) fruticoſus, foliis lineari-lanceolatis, hirſutis, ſeſſilibus, floribus terminalibus. *Shrubby Rock-roſe with narrow, ſpear-ſhaped, hairy leaves, ſitting cloſe to the branches, and flowers terminating the ſtalks.* Ciſtus ~~ledon~~ foliis oleæ ſed anguſtioribus. C. B. P. 167.
11. Cistus (*Laurifolius*) arboreſcens exſtipulatus foliis oblongo-ovatis petiolatis, trinerviis ſupra glabris. *Tree Rock-roſe with oblong oval leaves, having foot-ſtalks, ſmooth above, and the foot-ſtalks joined at their baſe.* Ciſtus ledon foliis laurinus. C. B. P. 476.
12. Cistus (*Cordifolius*) foliis oblongo-cordatis, glabris, petiolis longioribus, caule fruticoſo. *Rock-roſe with oblong, heart-ſhaped, ſmooth leaves, longer foot-ſtalks, and a ſhrubby ſtalk.*
13. Cistus (*Monſpelienſis*) arboreſcens exſtipulatus, foliis lineari-lanceolatis, ſeſſilibus, utrinque villoſis, trinerviis. Hort. Cliff. 205. *Tree Rock-roſe with linear ſpear-ſhaped leaves ſitting cloſe to the branches, hairy on both ſides, having three nerves.* Ciſtus ladanifera Monſpelienſum. C. B. P. 467.
14. Cistus (*Salicifolius*) arboreſcens, foliis lineari-lanceolatis, ſubtus incanis, trinerviis, petalis ſubrotundis. *Tree Rock-roſe with narrow ſpear-ſhaped leaves, hoary on their under ſide, having three nerves with roundiſh petals.* Ciſtus ladanifera Hiſpanica, ſalicis folio, flore albo, maculâ punicante inſignito. Tourn. Inſt. R. H. 260. *Spaniſh Gum-bearing Ciſtus with white flowers ſpotted with purple.*
15. Cistus (*Populifolius*) arboreſcens exſtipulatus, foliis cordatis lævibus acuminatis petiolatis. Hort. Cliff. 205. *Tree Rock-roſe with heart-ſhaped ſmooth leaves, having foot-ſtalks.* Ciſtus ledon foliis populi nigræ major. C. B. P. 467.
16. Cistus (*Criſpus*) arboreſcens exſtipulatus, foliis lanceolatis pubeſcentibus trinerviis undulatis. Hort. Cliff. 206. *Rock-roſe with ſpear-ſhaped, hairy, waved leaves, having three veins.* Ciſtus mas, foliis chamædryos. C. B. P. 464.
17. Cistus (*Halimifolius*) foliis ovatis, incanis, infernè petiolatis, ſupernè coalitis, caule fruticoſo. *Rock-roſe with oval hoary leaves, thoſe beneath having foot-ſtalks, and the upper ones joined at their baſe, and a ſhrubby ſtalk.* Ciſtus Halimi, folio 1. Cluſ. Hiſt. 1. p. 71. *Ciſtus with Sea Purſlane leaves.*
18. Cistus (*Longifolius*) foliis lineari-lanceolatis, incanis petiolatis, floribus racemoſis caule fruticoſo. *Rock-roſe with narrow ſpear-ſhaped leaves, having foot-ſtalks which are hoary, flowers growing in cluſters, and a ſhrubby ſtalk.* Ciſtus folio halimi longiore incano. J. B. 2. 5.

Theſe plants all grow naturally in the ſouth of France, in Spain, and Portugal, from whence their ſeeds have been brought to England, where moſt of the ſorts are now cultivated in the nurſeries for ſale. The firſt ſort hath a ſtrong woody ſtem, covered with a rough bark, which riſes three or four feet high, dividing into many branches, ſo as to form a large buſhy head; garniſhed with oval hairy leaves, placed oppoſite, and ſit cloſe to the branches, having ſeveral ſmaller leaves of the ſame form, riſing from the ſame joint. The flowers are produced at the end of the branches, four or five ſtanding together, almoſt in form of an umbel, but rarely more than one is open at the ſame time; theſe are compoſed of five large roundiſh petals of a purple colour, which ſpread open like a Roſe, having a great number of ſtamina, ſurrounding the oval germen in the center, terminated by ſmall, roundiſh, yellow ſummits; theſe flowers are but of ſhort duration, generally falling off the ſame day they expand; but there is a ſucceſſion of freſh flowers every day for a conſiderable time. After the flowers are paſt, the germen ſwells to an oval ſeed-veſſel, ſitting in the empalement, which is hairy; theſe capſules have ten cells, which are full of ſmall roundiſh ſeeds. This ſort flowers in May and June, and the ſeeds ripen in autumn; and there is generally more flowers produced in September and October, if the autumn proves favourable, and where the plants are protected from froſt, they frequently produce ſome flowers all the winter ſeaſon.

The ſecond ſort differs from the firſt in the ſhape of the leaves, which are longer and whiter; thoſe on the lower part of the branches are oval, and join at their baſe, ſurrounding the ſtalks, but the upper leaves are ſpear-ſhaped and diſtinct; the flowers are larger, and of a paler purple colour. This flowers and ripens ſeeds at the ſame time with the firſt.

The third ſort differs from both the former, in having ſhorter and greener leaves, which are joined at their baſe, and are hairy. The foot-ſtalks of the flowers are much longer, and the flowers are ſmaller, but of a deeper purple. This flowers and ſeeds at the ſame time with the two former, and the ſhrubs grow as large as the firſt ſort.

The fourth ſort hath much larger and rounder leaves than either of the former, which are hairy, and ſmooth on their upper ſide, but rough, and full of veins on their under; the branches are white, hairy, and the flowers are very large, and of a light purple colour. This flowers at the ſame time with the former.

The fifth ſort doth not riſe ſo high as either of the former, but ſends out branches near the root, which are hairy and erect, garniſhed with ſpear-ſhaped leaves, of a dark green colour, which join at their baſe, ſurrounding the ſtalk. At each joint comes out a very ſlender branch, having three pair of ſmall leaves of the ſame ſhape with the other, terminated by a ſingle flower; the ends of the branches have three or four flowers ſitting cloſe without foot-ſtalks. The flowers are of a deep purple colour, and like thoſe of the firſt. This flowers at the ſame time with the other ſorts.

The ſixth ſort riſes to the height of five or ſix feet, with a ſtrong woody ſtalk, ſending out many hairy branches, garniſhed with ſpear-ſhaped leaves, ſmooth on their upper ſide, but veined on their under, having ſhort foot-ſtalks, which join at their baſe, where they form a ſort of ſheath to the branch. The flowers come out at the end of the branches, which are large, of a light purple colour, and reſembling thoſe of the fourth ſort.

The ſeventh ſort hath erect branches, which come out from the lower part of the ſtalk, and are woolly; garniſhed with oblong hoary leaves, covered with a white down, which are ſmooth above, but veined on their under ſide, joining at their baſe where they ſurround the ſtalk; the flowers are produced at the end of the branches, which are of a bright purple colour, and large. This flowers at the ſame time with the other ſorts.

The eighth ſort hath a ſlender ſmooth ſtalk, covered with a brown bark, which never riſes more than three feet high, ſending out many horizontal weak branches, which ſpread wide, garniſhed with ſmall oval leaves, which are hairy, ſtanding upon ſhort foot-ſtalks. The flowers come out at the wings of the leaves, upon long naked foot-ſtalks; theſe are white, and ſomewhat ſmaller than thoſe of the other ſorts. This flowers in June, July, and Auguſt.

The ninth ſort grows naturally in the iſlands of the Archipelago; this is the plant which produces the labdanum, as is hereafter mentioned; it riſes three or four feet high, with a woody ſtalk, ſending out many lateral branches, covered with a brown bark, garniſhed with oval, ſpear-ſhaped, hairy leaves, with waved borders; theſe in warm ſeaſons ſweat a glutinous liquid, which ſpreads on the ſurface of the leaves, is very clammy and ſweet ſcented. The flowers come out at the end of the branches, on ſhort hairy foot-ſtalks; they are of a deep purple colour, and about the ſize of a ſingle Roſe; theſe appear in June and July.

The tenth ſort riſes with a ſhrubby ſtalk about four feet high, the branches are very hairy, glutinous, grow erect, and are garniſhed with long, narrow, hairy leaves, ending in points, of a deep green on both ſides, having a deep longitudinal furrow on their upper ſide, made by the midrib, which is prominent, the flowers ſtand upon long foot-ſtalks at the end of the branches, which are of a pale ſulphur colour, having a bordered empalement, which is cut into five acute parts at the top. This flowers in June, July, and Auguſt, and the ſeeds ripen in autumn.

The eleventh ſort riſes with a ſtrong woody ſtem to the height of five or ſix feet, ſending out many erect branches, garniſhed with ſpear-ſhaped leaves ending in points; theſe are thick, white on their under ſide, of a dark green above, and very glutinous in warm weather. The flowers are produced at the end of the branches, upon long naked foot-ſtalks, which branch on their ſides into ſmall foot-ſtalks, each ſuſtaining one large white flower, having a hairy empalement. This ſort flowers in June and July.

The twelfth ſort riſes with a ſmooth ſhrubby ſtalk four or five feet high, ſending out many ſlender ligneous branches, covered with a ſmooth brown bark; garniſhed with oblong heart-ſhaped leaves, which are ſmooth, and have long foot-ſtalks. The flowers are produced at the end of the branches, ſtanding upon pretty long foot-ſtalks; they are white, and appear in June, July, and Auguſt, but rarely produce any ſeeds in England.

The thirteenth ſort riſes with a ſlender ſhrubby ſtalk, from three to four feet high, ſending out many branches from the bottom upward, which are hairy, garniſhed with ſpear-ſhaped leaves, of a very dark green colour, having three longitudinal veins in each, and in warm weather are covered with a glutinous ſweet-ſcented ſubſtance, which exſudes from their pores. The flower-ſtalks which come out at the end of the branches, are long, naked, and ſuſtain many white flowers, riſing above each other; their empalements are bordered, and end in ſharp points. This flowers at the ſame time with the laſt mentioned.

The fourteenth ſort riſes with a woody ſtem to the height of five or ſix feet, ſending out many ſide branches from the bottom, the whole length; theſe are ſmooth, covered with a reddiſh brown bark, garniſhed with narrow ſpear-ſhaped leaves, whitiſh on their under ſide, of a dark green above, having three longitudinal veins. The flowers are produced at the end of the branches, on ſhort foot-ſtalks, and are compoſed of five very large, roundiſh, white petals, each having a large purple ſpot at their baſe. The whole plant exſudes a ſweet glutinous ſubſtance in warm weather, which hath a very ſtrong balſamic ſcent, ſo as to perfume the circumambient air to a great diſtance. This flowers in June, July, and Auguſt.

There is a variety of this with white flowers, having no purple ſpots, which is in all other reſpects the ſame with this.

The fifteenth ſort hath a ſtiff, ſlender, woody ſtalk, which ſends out many branches the whole length, and riſes to the height of ſix or ſeven feet; the leaves are large, heart-ſhaped, and of a light green colour; theſe ſit cloſe to the branches, having many nerves; the flowers are produced at the end of the branches, upon naked foot-ſtalks; they are white, and ſoon drop off. This flowers in June and July, and is at preſent pretty rare in the Engliſh gardens.

The ſixteenth ſort hath weak, ſlender, woody branches, which ſpread horizontally, ſo ſeldom riſe more than two or three feet high, garniſhed with ſpear-ſhaped hairy leaves, which are indented on their edges, and have three longitudinal veins running through them; the flowers are white, coming out upon naked foot-ſtalks from the wings of the leaves; theſe are ſucceeded by roundiſh blunt ſeed-veſſels, having ſeveral cells, filled with angular ſeeds. This flowers in June and July, and the ſeeds ripen in Auguſt and September.

The ſeventeenth ſort hath an upright ſhrubby ſtalk, which riſes four or five feet high, ſending out many branches from the ground upward, ſo as to form a large buſh. The branches are channelled and hoary. The leaves are oval, ſtanding oppoſite; thoſe on the lower part of the branches have foot-ſtalks, but upward they coaleſce at their baſe, and ſurround the ſtalk; they are very white. The foot-ſtalks of the flowers which riſe at the end of the branches, are a foot in length, naked, hairy, and put out two or four ſhorter foot-ſtalks on the ſide, each ſupporting three or four flowers. The flowers are large, of a bright yellow colour, but of ſhort duration; their empalements are hairy, and ſharp-pointed. This flowers in June and July, and at preſent is but in few Engliſh gardens.

The eighteenth ſort hath been long preſerved in the Engliſh gardens; this riſes with a ſlender woody ſtalk three or four feet high, ſending out many ſlender branches, garniſhed with narrow, ſpear-ſhaped, hoary, waved leaves; from the wings of the leaves come out ſlender branches, which have two or three pair of ſmall leaves, terminated by looſe bunches of flowers, each ſtanding on a ſlender foot-ſtalk. The flowers are of a dirty ſulphur colour, and appear in June and July, but are never ſucceeded by ſeeds in this country.

This ſort will not live abroad in the winter, ſo is always placed in a green-houſe, where, by its hoary leaves, which continue all the year, it makes a variety.

All the various kinds of Ciſtus are very great ornaments to a garden; their flowers are produced in great plenty, which though but of a ſhort duration, yet are ſucceeded by freſh ones almoſt every day for above two months ſucceſſively; theſe flowers are many of them about the bigneſs of a middling Roſe, but ſingle, and of different colours; the plants continue their leaves all the year.

Theſe plants are all of them, except the laſt, hardy enough to live in the open air in England, unleſs in very ſevere winters, which often deſtroys many of them, ſo that a plant or two of each ſort may be kept in pots, and ſheltered in winter, to preſerve the kinds; the reſt may be intermixed with other ſhrubs, where they will make a pretty diverſity; and in ſuch places where they are ſheltered by other plants, they will endure the cold much better than where they are ſcattered ſingly in the borders. Many of theſe plants will grow to the height of five or ſix feet, and will have large ſpreading heads, provided they are permitted to grow uncut; but if they are ever trimmed, it ſhould be only ſo much as to prevent their heads from growing too large for their ſtems; for whenever this happens, they are apt to fall on the ground, and appear unſightly.

Theſe ſhrubs are propagated by ſeeds, and alſo from cuttings; but the latter method is ſeldom practiſed, unleſs for thoſe ſorts which do not produce ſeeds in England; theſe are the twelfth, ſeventeenth, and eighteenth ſorts; all the others generally produce plenty of ſeeds, eſpecially thoſe plants which came from ſeeds; for thoſe which are propagated by cuttings, are very ſubject to become barren, which is alſo common to many other plants.

The ſeeds of theſe plants may be ſown in the ſpring upon a common border of light earth, where the plants will come up in ſix or ſeven weeks, and, if they are kept clear from weeds, and thinned where they are too cloſe, they will grow eight or ten inches high the ſame year; but as theſe plants, when young, are liable to injury from hard froſt, therefore they ſhould be tranſplanted when they are about an inch high, ſome into ſmall pots filled with light earth, that they may be removed into ſhelter in winter, and the others into a warm border, at about ſix inches diſtance each way; thoſe which are potted, muſt be ſet in a ſhady ſituation till they have taken new root; and thoſe planted in the border muſt be ſhaded every day with mats till they are rooted, after which the latter will require no other care but to keep them clean from weeds till autumn, when they ſhould have hoops placed over them, that they may be covered in froſty weather; thoſe in the pots may be removed into an open ſituation, ſo ſoon as they have taken new root, where they may remain till the end of October, but during the ſummer they muſt be ſhifted into larger pots, and be frequently watered; the end of October they ſhould be placed under a hot-bed frame to ſcreen them from the cold in winter, but, at all times, when the weather is mild, they ſhould be fully expoſed to the open air, and only covered in froſts: with this management, the plants will thrive much better than when they are more tenderly treated.

The above method is what the gardeners generally practiſe; but thoſe who are deſirous to have their plants come forward, ſhould ſow the ſeeds on a moderate hot-bed in the ſpring, which will bring up the plants very ſoon; but theſe muſt have plenty of air when they appear, otherwiſe they will draw up very weak; when the plants are fit to remove, they ſhould be each planted into a ſeparate ſmall pot, and plunged into a very moderate hot-bed, obſerving to ſhade them till they have taken freſh root; then they muſt have plenty of air admitted to them every day in good weather, to prevent their drawing up weak; and by degrees they muſt be hardened, ſo as to be removed into the open air the beginning of June, and then they may be treated in the ſame manner as is before directed for the other ſeedling plants. By the bringing of the plants forward in the ſpring in this method, they will grow to the height of two feet, or more, the firſt ſummer, and have many lateral branches, ſo will be ſtrong enough to plant abroad the following ſpring, and moſt of them will flower the ſame ſummer; whereas thoſe which are ſown in the full ground, rarely flower till the year after; nor will they be ſo ſtrong, or capable to reſiſt the cold of the ſecond winter, as thoſe which have been brought forward.

In the ſpring following, theſe plants may be turned out of the pots, with all the earth preſerved to their roots, and planted in the places where they are to remain (for they are bad plants to remove when grown old,) obſerving to give them now and then a little water, until they have taken freſh root; after which time, they will require no farther care than to train them upright in the manner you would have them grow; but thoſe plants which were at firſt planted into a border in the open ground, ſhould be arched over, and covered with mats in froſty weather, during the firſt winter, but may be tranſplanted abroad the ſucceeding ſpring. In removing of theſe plants, you ſhould be careful to preſerve as much earth about the roots as you can; and if the ſeaſon ſhould prove hot and dry, you muſt water and ſhade them until they have taken freſh root, after which they will require no other culture than was before directed.

Theſe plants may alſo be propagated by cuttings, which ſhould be planted in May or June, upon a bed of light earth, keeping them ſhaded with mats, and frequently refreſhed with water, until they have taken root; which will be in about two months time, when you may tranſplant them into pots filled with good freſh light earth, and they ſhould be ſet in a ſhady place until they have taken root, then they may be expoſed to the open ſun until October, when you ſhould remove them into ſhelter the firſt winter; but the ſucceeding ſpring you may plant them abroad, as was before directed for the ſeedling plants.

The fourteenth and fifteenth ſorts are by much the moſt beautiful of all theſe Ciſtus's; the flowers, which are as big as a large Roſe, are of a fine white, with a deep purple ſpot on the bottom of each leaf. Theſe plants alſo abound with a ſweet glutinous liquor, which exſudes through the pores of the leaves in ſo plentiful a manner in hot weather, that the ſurfaces of the leaves are covered therewith; from this plant Cluſius thinks might be gathered great quantities of the ladanum which is uſed in medicine, in the woods in Spain, where he ſaw vaſt quantities of this ſhrub growing.

But it is from the ninth ſort, which Monſ. Tournefort ſays, the Greeks, in the Archipelago, gather this ſweet gum; in the doing of which (Bellonius ſays) they make uſe of an inſtrument like a rake without teeth, which they call ergaſtiri; to this are tied many thongs of raw and untanned leather, which they rub gently on the buſhes that produce ladanum, ſo that the liquid moiſture may ſtick upon the thongs, after which they ſcrape it off with knives; this is done in the hotteſt time of the day, for which reaſon the labour of gathering this ladanum is exceſſive, and almoſt intolerable, ſince they are obliged to remain on the mountains for whole days together, in the very heat of ſummer, or the dog days; nor is there any perſon almoſt that will undertake this labour, except the Greek monks.

Monſ. Tournefort alſo relates the ſame in his travels, where he ſays, that the ſhrubs which produce the ladanum grow upon dry ſandy hillocks; and that he obſerved ſeveral country fellows in their ſhirts and drawers, that were bruſhing the ſhrubs with their whips; the ſtraps whereof, by being drawn over the leaves of the plant, licked up a ſort of odoriferous balſam ſticking upon the leaves, which he ſuppoſes to be part of the nutritious juice of the plant, which exſudes through the pores of the leaves, where it remains like a fattiſh dew, in ſhining drops as clear as turpentine.

When the whips are ſufficiently laden with this greaſe, they take a knife, and ſcrape it clean off the ſtraps, and make it up into a maſs of cakes of different ſizes; this is what comes to us under the name of ladanum, or labdanum. A man that is diligent, will gather three pounds two ounces per day, or more, which they ſell for a crown on the ſpot; this work is rather unpleaſant than laborious, becauſe it muſt be done in the hotteſt time of the day, and in the greateſt calm; and yet the pureſt ladanum is not free from filth, becauſe the winds of the preceding days have blown duſt upon theſe ſhrubs, which, by the glewy ſubſtance upon the ſurfaces of the leaves, is thereby detained and mixed therewith. But to add weight to this drug, they knead it up with a very fine blackiſh ſand, which is found in thoſe parts, as if nature herſelf was minded to teach them how to adulterate this commodity. It is no eaſy thing to diſcover this cheat, when the ſand has been well blended with the ladanum; in order to which you muſt chew it for ſome time, to find whether it crackles between the teeth, and if it doth, you muſt firſt diſſolve it, and then ſtrain it, in order to purify away what has been added to it.

CITHAREXYLUM. Lin. Gen. Plant. 678. Fiddle-wood.

The CHARACTERS are,

The empalement of the flower is bell-ſhaped, of one leaf, indented in five parts. The flower is of one leaf, funnel-ſhaped, divided at the top into five equal parts, which ſpread open. It hath four ſtamina which adhere to the tube, two of them being longer than the other, terminated by oblong ſummits with two lobes. In the center is ſituated the roundiſh germen, ſupporting a ſlender ſtyle, crowned by an obtuſe double-headed ſtigma. The germen afterward becomes a capſule with two cells, each having a ſingle ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia; the plants of this ſection have two long, and two ſhort ſtamina, and the ſeeds are included in a capſule.

The SPECIES are,

1. CITHAREXYLUM (*Cinereum*) ramis angulatis, foliis ovato-lanceolatis venis candicantibus. *Fiddle-wood with angular branches, and oval ſpear-ſhaped leaves, having white veins.* Citharexylum arbor laurifolia Americana, foliorum venis latis candicantibus. Pluk. Almag. 108. *Fiddle-wood with oval ſpear-ſhaped leaves, which are veined, indented, and placed by threes, angular branches, and flowers growing in looſe bunches. This is the common Fiddle-wood of America.*

2. CITHAREXYLUM (*Album*) foliis oblongo-ovatis, integris, oppoſitis, ramis angulatis, floribus ſpicatis. *Fiddle-wood with oblong, oval, entire leaves growing oppoſite, angular branches, and flowers growing in ſpikes.* Berberis fructu arbor maxima baccifera, racemoſa, foliis integris obtuſis, flore albo pentapetalo odoratiſſimo, fructu nigro monopyreno. Sloan. Cat. Jam. 170. *Fiddle-wood, or Fidelle-wood.*

The firſt ſort grows common in moſt of the iſlands in the Weſt-Indies, where it riſes to a great height, and becomes a very large timber-tree; the wood of which is greatly eſteemed for buildings, being very durable.

This hath an upright trunk fifty or ſixty feet high, ſending out branches on every ſide, which have ſeveral angles, or ribs, running longitudinally, garniſhed by three oval ſpear-ſhaped leaves at every joint, ſtanding in a triangle, upon ſhort foot-ſtalks. The leaves are about four inches long, and one or two broad, of a lively green colour, pretty much notched on their edges, having ſeveral deep veins running from the midrib to the edges, which are of a white colour on their upper ſide, and very prominent on their under. The flowers come out from the ſides, and alſo at the end of the branches, in looſe bunches, which are ſucceeded by ſmall pulpy berries, incloſing two ſeeds in each.

The ſecond ſort is a native of the ſame iſlands with the firſt. This is alſo a very large tree, whoſe timber is greatly valued in America, for buildings, being very durable; and from thence I have been informed the French gave it the title of Fidelle-wood, which the Engliſh have rendered Fiddle-wood; and ſome have ſuppoſed that the wood was uſed for making thoſe muſical inſtruments, which is a great miſtake.

This tree riſes with a ſtrong upright trunk to the height of ſixty feet or more, ſending out many angular branches, ſtanding oppoſite, which are covered with a looſe whitiſh bark, (from whence the inhabitants give it the name of white Fiddle-wood,) garniſhed with oval oblong leaves, ſtanding oppoſite, on ſhort foot-ſtalks; theſe are of a lucid green, and are rounded at their ends. The flowers come out in long looſe ſpikes, toward the end of the branches, which are white, and ſmell very ſweet; theſe are followed by ſmall, roundiſh, pulpy berries, each incloſing a ſingle ſeed.

The firſt ſort hath been long preſerved in ſome of the curious gardens in England, for the ſake of variety. The leaves continuing through the year, and being of a fine green colour, make a pretty variety in the ſtove during the winter ſeaſon: this may be propagated either by ſeeds, or cuttings; the latter is the uſual method in England, where the ſeeds are not produced; but when ſeeds can be obtained from abroad, the plants which riſe from them are much better than thoſe raiſed from cuttings.

The ſeeds of this ſort ſhould be ſown in ſmall pots early in the ſpring, and plunged into a freſh hot-bed of tanners bark, and treated in the ſame manner as other exotic ſeeds, which are brought from hot countries. If the ſeeds are freſh, the plants will appear in ſix or ſeven weeks, and in about one month more will be fit to tranſplant; when this is done, the plants ſhould be carefully ſeparated, ſo as not to tear, or break off their roots, and each planted in a ſmall pot filled with light freſh earth, and plunged into the hot-bed again, obſerving to ſhade them till they have taken freſh root; after which they ſhould have a large ſhare of air admitted to them in warm weather, and muſt be frequently watered; in autumn the plants ſhould be removed into the bark-ſtove, where it will be proper to keep them the firſt winter, till they have obtained ſtrength; then they may be afterward kept in a dry ſtove in winter, and in the middle of ſummer they may be expoſed in the open air for two or three months, in a warm ſituation, with which management the plants will make better progreſs than when they are more tenderly treated.

If the cuttings of theſe plants are planted in ſmall pots during the ſummer months, and plunged into a moderate hot-bed, they will take root, and may afterward be treated in the ſame manner as the ſeedling plants.

The ſeeds of the ſecond ſort were ſent me by William Williams, Eſq; from Jamaica, which have ſucceeded in the phyſic garden at Chelſea; but as the plants have not yet flowered, I can give no other account of them, than what is before-mentioned; however, they ſeem to be full as hardy as thoſe of the firſt ſort, and make full as great progreſs. The leaves of this ſort continue all the year, and having a gloſſy green colour, make a pretty appearance in the winter ſeaſon.

CITRUS. Lin. Gen. Plant. 807. Citreum. Tourn. Inſt. R. H. 620. tab. 395, 396. The Citron-tree.

The CHARACTERS are,

The empalement of the flower is of one leaf, indented in five parts. The flower hath five oblong, thick petals, which ſpread open, and are a little concave; it hath ten ſtamina, which are not equal, and join in three bodies at their baſe, terminated by oblong ſummits. The oval germen in the center ſupports a cylindrical ſtyle, crowned by a globular ſtigma; the germen afterward becomes an oblong fruit, with a thick fleſhy ſkin filled with a ſucculent pulp, having many cells, each containing two oval hard ſeeds.

Dr. Linnæus has joined the Aurantium and Limon to this genus, making them only different ſpecies of the ſame genus; but all the varieties of Citron which

I have examined, have but ten ſtamina in their flowers, whereas thoſe of the Orange have more, ſo that theſe may be ſeparated on that difference; but Tournefort adds, as a diſtinguiſhing character to this genus, the appendix which grows to the foot-ſtalk of the leaf. However, I ſhall not ſo cloſely follow Linnæus, in joining thoſe things together, which have by all the writers on botany and gardening been kept ſeparate, leſt I ſhould render this work unintelligible to thoſe who have not made botany their ſtudy.

The Species are,

1. Citrus (*Medica*) fructu oblongo, majori, mucronato, cortice craſſo rugoſo. *Citron with a larger, oblong, pointed fruit, having a thick rough rind.* Malum Citreum dulci medulla. Fer. Heſp. 72. *The Sweet Citron.*
2. Citrus (*Tuberoſa*) fructu oblongo, cortice tuberoſa rugoſo. *Citron with an oblong fruit, having a rough knobbed rind.* Malum Citreum vulgare. Fer. Heſp. 57. *The common Citron.*

There are ſeveral varieties of this fruit, with which the Engliſh gardens have been ſupplied from Genoa, where is the great nurſery for the ſeveral parts of Europe for this ſort, as alſo Orange and Lemon-trees; and the gardeners who cultivate them there, are as fond of introducing a new variety to their collection, as the nurſery-men in England are of a new Pear, Apple, Peach, &c. ſo that the varieties being annually increaſed, as are many of our fruits from ſeeds, there is like to be no end of the vatiety of theſe, nor of the Orange and Lemon-trees.

The fruit of the Citron is ſeldom eaten raw, as thoſe of the Orange, but they are generally preſerved, and made into ſweetmeats, which are by ſome perſons greatly eſteemed; and as theſe are kept till winter and ſpring, when there is a ſcarcity of fruit for furniſhing out the deſert, they are the more valuable; but unleſs the ſeaſons are warm, and the trees are well managed, the fruit rarely ripens in England. Some of the faireſt fruit which I have ſeen growing in England, were in the gardens of his late grace the Duke of Argyle, at Whitton, where the trees were trained againſt a ſouth wall, through which there are flues contrived for warming the air in winter, and glaſs-covers to put over them when the weather begins to be cold. In this place the fruit were as large, and perfectly ripe, as they are in Italy or Spain.

The ſeveral ſorts of Citrons are cultivated much in the ſame manner as the Orange-tree, to which I ſhall refer the reader, to avoid repetition; but ſhall only remark, that theſe are ſomewhat tenderer than the Orange, and ſhould therefore have a warmer ſituation in winter, otherwiſe they are very ſubject to caſt their fruit. They ſhould alſo continue a little longer in the houſe in the ſpring, and be carried in again ſooner in the autumn; as alſo have a warmer and better defended ſituation in the ſummer, though not too much expoſed to the ſun in the heat of the day.

And as their leaves are larger, and their ſhoots ſtronger, than thoſe of the Orange, they require a little more water in the ſummer; but in winter they ſhould have but little water at each time, which muſt be the oftener repeated. The ſoil ought to be much the ſame as for the Orange-tree, but not quite ſo ſtrong.

The common Citron is much the beſt ſtock to bud any of the Orange or Lemon kinds upon, it being the ſtraiteſt and freeſt growing tree. The rind is ſmoother, and the wood leſs knotty, than either the Orange or Lemon; and will take either ſort full as well as its own kind, which is what none of the other ſorts will do: and theſe ſtocks, if rightly managed, will be very ſtrong the ſecond year after ſowing, capable to receive any buds, and will have ſtrength to force them out vigorouſly; whereas it often happens, when theſe buds are inoculated into weak ſtocks, they frequently die, or remain till the ſecond year before they put out; and thoſe that ſhoot the next ſpring after budding, are oftentimes ſo weak as hardly to be fit to remain, being incapable to make a ſtrait handſome ſtem, which is the great beauty of theſe trees.

CITRUL. See Pepo.

CLARY. See Sclarea.

CLAYTONIA. Gron. Flor. Virg. Lin. Gen. Plant. 253.

The Characters are,

The flower hath a two-leaved oval empalement, with a tranſverſe baſe: it hath five oblong oval petals, which are indented at the top, and five awl-ſhaped recurved ſtamina, which are ſhorter than the petals, terminated by oblong ſummits. In the center is ſituated an oval germen, ſupporting a ſingle ſtyle, crowned by a trifid ſtigma. The germen afterward becomes a roundiſh capſule, having three cells, opening with three elaſtic valves, and filled with round ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and but one ſtyle.

The Species are,

1. Claytonia (*Virginica*) foliis linearibus. Lin. Sp. Plant. 294. *Claytonia with very narrow leaves.* Ornithogalo affinis Virginiana, flore purpureo pentapetaloide. Pluk. Alm. 272.
2. Claytonia (*Siberica*) foliis ovatis. Lin. Sp. Plant. 294. *Claytonia with oval leaves.* Limnia. Act. Stockh. 1746.

The firſt ſort grows naturally in Virginia, from whence it was ſent by Mr. Clayton to England, and received its title from him.

It hath a ſmall tuberous root, which ſends out low ſlender ſtalks in the ſpring, about three inches high, which have each two or three ſucculent narrow leaves about two inches long, of a deep green colour. At the top of the ſtalk are four or five flowers produced, ſtanding in a looſe bunch; theſe are compoſed of five white petals which ſpread open, and are ſpotted with red on their inſide; after theſe fall away, the germen becomes a roundiſh capſule divided into three cells, which are filled with roundiſh ſeeds. The flowers appear in April, and the ſeeds ripen in June, ſoon after which the plant decays to the root.

The ſecond ſort grows naturally in Siberia. This is a low plant, ſeldom riſing more than two or three inches high; the root is tuberous, ſending out three or four oval leaves; the foot-ſtalk of the flower ariſes immediately from the root, ſuſtaining two or three ſmall white flowers of the ſame ſhape with thoſe of the firſt ſort, ſo make but little figure in a garden.

The plants are both propagated by ſeeds, and alſo from offſets ſent out from the roots: the ſeeds ſhould be ſown upon a ſhady border of light earth, or in pots filled with the like mould, ſoon after they are ripe; for if they are kept out of the ground till ſpring, the plants will not come up till the next year; whereas thoſe which are ſown early in the autumn, will grow the following ſpring, ſo that a whole year is gained. When the plants come up, they will require no other care but to keep them clean from weeds; and in the autumn, if ſome old tanners bark is ſpread over the ſurface of the ground, it will ſecure the roots from being injured by froſt; which, if it ſhould prove very ſevere, might injure the young plants, but in mild winters they will not require protection.

The beſt time to tranſplant the roots is about Michaelmas, when they are inactive; but as they are ſmall, if great care is not taken in opening the ground, the roots may be buried and loſt; for they are of a dark colour, ſo are not eaſily diſtinguiſhed from the ground.

CLAVICLE [Claviculus, *Lat.*] a claſper or tendril.

CLEMATIS. Lin. Gen. Plant. 616. Clematitis. C. B. P. 300. [Κληματὶς, of Κλῆμα, a twig or claſper, &c. becauſe it climbs up trees with claſpers, like thoſe of Vines. Hence it is called Virgultum ductile, Ranunculus obſequioſus; and alſo Antrogenomene, and Flammula, as though producing a carbuncle; for the leaves being bruiſed, and applied to the ſkin, burn it into carbuncles, as it is in the peſtilence;

lence; and Flammula, becauſe if one leaf be cropped in a hot day in the ſummer ſeaſon, and bruiſed, and preſently put to the noſtrils, it will cauſe a ſmell and pain like a flame.] Virgin's Bower.

The CHARACTERS are,

The flowers have no empalement; they have each four looſe oblong petals, with a great number of ſtamina, which are ſhorter than the petals, and the ſummits adhere to their ſide. They have many germen, which are roundiſh and compreſſed; the awl-ſhaped ſtyle, which is longer than the ſtamina, is crowned by a ſingle ſtigma. The germina afterward become ſo many roundiſh compreſſed ſeeds, with the ſtyle ſitting on their top, and are collected into a head, the ſtyles of the ſeveral ſpecies being of various forms.

This genus of plants is ranged in the ſeventh ſection of Linnæus's thirteenth claſs, intitled Polyandria Polygynia, the flowers of this ſection having many ſtamina and ſeveral ſtyles.

The SPECIES are,

1. CLEMATIS (*Recta*) foliis pinnatis, foliolis ovato-lanceolatis, integerrimis, caule erecto. Hort. Cliff. 225. *Clematis with winged leaves, whoſe lobes are oval, ſpear-ſhaped, entire, and an upright ſtalk.* Clematitis ſive flammula ſurrecta alba. J. B. 2. 127. *Upright white Climber.*
2. CLEMATIS (*Integrifolia*) foliis ſimplicibus, ovato-lanceolatis. Hort. Cliff. 225. *Clematis with ſingle leaves, which are oval and ſpear-ſhaped.* Clematitis cærulea erecta. C. B. P. 300. *Upright blue Climber.*

The firſt ſort grows naturally in the ſouth of France, Italy, Auſtria, and ſeveral parts of Germany, but hath been long cultivated in the Engliſh gardens for ornament. This hath a perennial root. The ſtalks are upright, about three or four feet high, garniſhed with winged leaves ſtanding oppoſite, which are compoſed of three or four pair of lobes, terminated by an odd one; they are oval, ſpear-ſhaped, and entire: the flowers are produced in large looſe panicles at the top of the ſtalks; theſe are compoſed of four white petals, which ſpread open; and the middle is occupied by a great number of ſtamina, ſurrounding five or ſix germen, which afterward become ſo many compreſſed ſeeds, each having a long tail or beard ſitting on the top. It flowers in June, and the ſeeds ripen in September.

The ſecond ſort grows naturally in Hungary and Tartary, but hath been long an inhabitant in the Engliſh gardens. The root of this is perennial, ſending up many ſlender upright ſtalks, from three to four feet high, garniſhed with oppoſite ſingle leaves at each joint, having ſhort foot-ſtalks; the leaves are near four inches long, and an inch and an half broad in the middle, of a bright green, ſmooth, and entire, ending in a point: the flowers come out from the upper part of the ſtalks, ſtanding upon very long naked foot-ſtalks, each ſupporting a ſingle blue flower, compoſed of four narrow thick petals which ſpread open, and many hairy ſtamina ſurrounding the germina in the center. After the flowers are paſt, the germen become ſo many compreſſed ſeeds, each having a tail or beard. It flowers and ſeeds at the ſame time with the former ſort.

The third ſort is very like the firſt, from which it differs in having but two or three pair of lobes in each leaf, which are narrower and ſtand farther aſunder: the ſtalks are ſhorter, and the flowers larger.

The fourth ſort grows naturally in the hedges, in moſt parts of England. This hath a tough climbing ſtalk, ſending out claſpers, by which it faſtens to the neighbouring buſhes and trees, and ſometimes riſes more than twenty feet high, ſending out many ſide branches, ſo as often to cover all the trees and buſhes of the hedge. This puts out many bunches of white flowers in June, which are ſucceeded by ſeveral flat ſeeds joined in a head, each having a long twiſted tail ſitting on the top, which is covered with long white hairs; and in autumn, when the ſeeds are near ripe, they appear like beards, from whence the country people call it Old Man's Beard. The branches of this being very tough and flexible, are uſed for tying up faggots; from whence, in ſome countries, it is called Bindwith.

There are two varieties of this, one with indented leaves, which is the moſt common, and the other hath entire leaves; but as theſe are ſuppoſed to ariſe accidentally from ſeeds, they are not diſtinguiſhed by later botaniſts.

The fifth ſort grows naturally in moſt parts of North America, from whence the ſeeds have been brought to Europe. This is in its firſt appearance very like the laſt ſort, but the leaves are broader, and grow by threes on the ſame foot-ſtalk, whereas thoſe of the former have five or ſeven lobes in each leaf. The flowers appear at the ſame time with the former, but the ſeeds do not ripen in England, unleſs the ſeaſon is very warm. There is little beauty in this ſort.

The ſixth ſort hath a climbing ſtalk like the fourth; the lower leaves of this are winged, and deeply cut on their edges, but the upper leaves are ſingle, ſpear-ſhaped, and entire. The flowers of this ſort are white, and appear in June or July. This grows naturally in the ſouth of France, and in Italy.

The ſeventh ſort grows naturally in Spain and Portugal. This hath a climbing ſtalk, which will riſe to the height of eight or ten feet, ſending out branches from every joint, whereby it becomes a very thick buſhy plant; the leaves are ſometimes ſingle, at other times double, and frequently trifoliate, being indented on their edges. Theſe keep their verdure all the year: oppoſite to the leaves come out claſpers, which faſten themſelves to the neighbouring ſhrubs, by which the branches are ſupported, otherwiſe they would fall to the ground. The flowers are produced from the ſide of the branches; theſe are large, of an herbaceous colour, and appear always about the end of December, or beginning of January, which being a ſeaſon when few perſons viſit gardens for information, theſe flowers have eſcaped their notice, ſo that many have ſuppoſed this ſort doth not produce flowers in England; and the flowers being nearly the ſame colour of the leaves, thoſe who have been more conſtant viſitors of gardens, have paſſed by this plant, without noticing the flowers; but for many years together, it hath produced plenty of flowers in the garden at Chelſea, and always at the ſame ſeaſon.

The ſeventh ſort is cultivated in the nurſery-gardens for ſale, and is known by the title of Virgin's Bower. There are four varieties of it which are preſerved in the gardens of the curious, and have been by ſome treated as ſo many diſtinct ſpecies; but as their only differences conſiſt either in the colour of their flowers, or the multiplicity of their petals, they are now only eſteemed as ſeminal variations; but as they are diſtinguiſhed by the nurſery-gardeners, I ſhall juſt mention them.

1. Single blue Virgin's Bower.
2. Single purple Virgin's Bower.
3. Single red Virgin's Bower.
4. Double purple Virgin's Bower.

Theſe have no difference in their ſtalks or leaves, ſo that the ſame deſcription will fit them all, excepting the colours or multiplicity of petals in their flowers. The ſtalks of theſe plants are very ſlender and weak, having many joints, from whence come out ſide branches, which are again divided into ſmaller. If theſe are ſupported, they will riſe to the height of eight or ten feet, and are garniſhed with compound winged leaves, placed oppoſite at the joints. Theſe branch out into many diviſions, each of which hath a ſlender foot-ſtalk, with three ſmall leaves, which are oval and entire: from the ſame joint, generally four foot-ſtalks ariſe, two on each ſide; the two lower have three of theſe diviſions, ſo that they are each compoſed of nine ſmall leaves or lobes; but the two upper have only two oppoſite leaves on each, and between theſe ariſe three ſlender foot-ſtalks, each ſupporting one flower. The flowers have each four petals, which are narrow at their baſe, but are broad at the top and rounded: in one they are of a dark worn-out purple, in another blue, and the third of a bright purple or red colour. The double ſort, which is common in the Engliſh gardens, is of the worn-out purple colour: but the foreign catalogues mention double flowers of both the other colours, which may probably be found in ſome of their gardens; but as I have not ſeen them myſelf, I have not noticed them. The double flowers have no ſtamina or germen, but in lieu of them, there is a multiplicity of petals, which are narrow, and turn inward at the top.

Theſe plants grow naturally in the woods in Spain and Portugal, but have been long cultivated in the Engliſh gardens for ornament. They flower in June and July, but they ſeldom ripen ſeeds in England, and the double ſort continues to the end of Auguſt.

The ninth ſort grows naturally on the Alps, and other mountains in Italy. I received it from mount Baldus, where it grows in plenty. This hath a ſlender climbing ſtalk, which riſes three or four feet high, ſupporting itſelf by faſtening to the neighbouring plants or ſhrubs. The leaves of this are compoſed of nine lobes or ſmall leaves, three ſtanding upon each foot-ſtalk, ſo that it is what the former writers ſtile a nine-leaved plant. The flowers come out at the joints of the ſtalk, in the ſame manner as the common Travellers Joy, which are white, ſo make no great appearance. This ſort flowers in May.

The tenth ſort grows naturally in Virginia and Carolina, from both of theſe countries I have received the ſeeds. This hath many ſlender ſtalks, garniſhed with compound winged leaves at each joint, and are generally compoſed of nine leaves, ſtanding by threes, like thoſe of the eighth ſort, but the ſmall leaves or lobes of this are nearly of a heart-ſhape. The flowers of this ſtand upon ſhort foot-ſtalks, which come out from the wings of the leaves, one on each ſide the ſtalk. The flowers are compoſed of four thick petals, which are purple on their outſide, and blue within. They appear in July, and if the autumn proves warm, the ſeeds will ripen in September.

The eleventh ſort was diſcovered by Dr. Tournefort in the Levant, from whence he ſent the ſeeds to the royal garden at Paris, where they ſucceeded and perfected ſeeds, ſo that moſt of the gardens in Europe have been furniſhed with the ſeeds from thence: this hath weak climbing ſtalks, which faſten themſelves by their claſpers, to any plants or ſhrubs which ſtand near them, and thereby riſe to the height of ſeven or eight feet, garniſhed with compound winged leaves, conſiſting of nine ſmall leaves (or lobes) which are angular and ſharp-pointed. The flowers come out from the wings of the leaves, which are of a yellowiſh green, and the petals are reflexed backward; they come out in April and May, and in warm ſeaſons the ſeeds will ripen very well, if the plants have a good ſituation.

The twelfth ſort grows naturally in Siberia, from whence the ſeeds were ſent to the imperial garden at Peterſburgh, where they ſucceeded and produced ſeeds, part of which were ſent me in the year 1753. Theſe grew, and the plants have flowered ſeveral years in the Chelſea garden. It hath weak climbing ſtalks which require ſupport, that riſe from four to ſix or eight feet high; the joints are far aſunder; at each of theſe come out two compound winged leaves, whoſe ſmall leaves or lobes are placed by threes; theſe are deeply ſawed on their edges, and terminate in ſharp points. The flowers come out from the wings of the leaves ſingle, ſtanding upon long naked foot-ſtalks, and are compoſed of four broad obtuſe petals, which ſpread open in form of a croſs, of a whitiſh yellow colour. In the center is placed ſeveral germen, ſurrounded by a great number of ſtamina, with flat compreſſed ſummits, of the ſame colour with the petals of the flower; after theſe are paſt, the germen become ſo many compreſſed ſeeds, each having a bearded tail. It flowers in February March and April, and the ſeeds ripen in July or Auguſt.

The thirteenth ſort was ſent me from Jamaica by the late Dr. Houſtoun. This hath ſlender climbing ſtalks, which faſten themſelves to the trees and ſhrubs which ſtand near them, and thereby riſe to the height of ten or twelve feet, garniſhed with trifoliate leaves, coming out on each ſide the ſtalk; the lobes are large, oval, and entire, having three longitudinal veins. The foot-ſtalks of the flowers ariſe at the ſame joints, cloſe to thoſe of the leaves, one on each ſide the ſtalks: theſe are long, naked, and grow horizontally, extending beyond the leaves before they divide and branch; then there comes out three or four pair of ſmall foot-ſtalks from the large one, each of which divides again into three ſmaller, each ſupporting a ſingle flower: the lower pair of theſe are extended four or five inches, the other gradually diminiſh to the top, ſo that they form a pyramidal thyrſe of flowers; theſe are white, and are compoſed of four narrow petals which are reflexed back, but the ſtamina all ſtand erect.

This hath been by ſome perſons ſuppoſed to be the ſame with the common Travellers Joy, but thoſe who have ſeen the two plants, cannot doubt of their being diſtinct ſpecies.

The fourteenth ſort was ſent me from Campeachy by the late Dr. Houſtoun. This hath ſtrong climbing ſtalks, which faſten themſelves by their claſpers to the neighbouring trees, whereby they are ſupported, and riſe to the height of twenty feet or more, garniſhed at each joint by trifoliate leaves, which are heart-ſhaped, pointed, and entire. The flowers come out on long, naked, branching foot-ſtalks, which riſe from the wings of the leaves; they are white, and collected into roundiſh bunches; theſe are ſucceeded by ſeeds ſhaped like thoſe of the common ſort, but have long curling beards to each, which are finely feathered.

The fifteenth ſort grows naturally in Carolina, from whence I received the ſeeds in the year 1726. This hath weak ſtalks which riſe near four feet high, and by their claſpers faſten themſelves to the neighbouring plants, whereby they are ſupported. The leaves come out oppoſite at the joints; theſe are ſometimes ſingle, at others trifoliate, and ſome of the leaves are divided into three lobes. The flowers come out ſingly from the ſide of the branches upon ſhort foot-ſtalks, which have one or two pair of leaves below the flower, which are oblong and ſharp-pointed. The flowers have four thick petals, like thoſe of the tenth ſort; theſe are of a purple colour, and their inner ſurface is curled, and hath many longitudinal furrows. This flowers in July, and the ſeeds ripen in September.

The three firſt ſorts have perennial roots, which multiply pretty faſt, but their ſtalks die down every autumn, and new ones ariſe in the ſpring, in which particular they differ from all the other ſpecies, therefore require different management, and are propagated in a different manner; therefore I ſhall firſt give directions for their culture.

Theſe plants are propagated either by ſeeds, or parting their roots; but the former being a tedious method (the plants ſeldom riſing until the ſecond year after ſowing, unleſs the ſeeds are ſown in the autumn ſoon after they are ripe, and are often two years more before they flower,) the latter is generally practiſed. The beſt ſeaſon for parting theſe roots is in October or February; either juſt before their branches decay, or before they riſe again in the ſpring.

They will grow almoſt in any ſoil or ſituation; but if the ſoil is very dry, they ſhould always be new planted in the autumn, otherwiſe their flowers will not be ſo ſtrong; but if the ſoil be wet, it is better to defer it until the ſpring. The roots may be cut through their crowns with a ſharp knife, obſerving to preſerve to every offſet ſome good buds or eyes; and then it matters not how ſmall you divide them, for their roots increaſe very faſt: but if you part them very ſmall, you ſhould let them remain three or four years before they are again removed, that their flowers may be ſtrong, and their roots multiplied in eyes, which in leſs time cannot be obtained.

Theſe plants are extreme hardy, enduring the cold of our ſevereſt winters in the open air, and are very proper ornaments for large gardens, either to be planted in large borders, or intermixed with other hardy flowers in quarters of flowering ſhrubs; where, by being placed promiſcuouſly in little open places, they fill up thoſe ſmall vacancies, and are agreeable enough. They begin to flower about the beginning of June, and often continue to produce freſh flowers until Auguſt, which renders them valuable, eſpecially ſince they require very little care in their culture; for their roots may be ſuffered to remain ſeveral years undiſturbed, where there is no want to part them, which will not in the leaſt prejudice them.

The fourth ſort is found wild in moſt parts of England, growing upon the ſides of banks under hedges, and extends its trailing branches over the trees and ſhrubs that are near it. This plant in the autumn is generally covered with ſeeds, which are collected into little heads, each of which having, as it were, a rough plume faſtened to it, hath occaſioned the country people to give it the name of Old Man's Beard. It is titled by Lobel and Gerard, Viorna; and by Dodonæus, Vitis alba: in Engliſh it is moſt commonly called Travellers Joy. This ſort is rarely cultivated in gardens, being too rambling, and having but little beauty.

The fifth and ſixth ſorts have no more beauty than the fourth, ſo are ſeldom preſerved in gardens, unleſs for the ſake of variety. They are both as hardy as the common ſort, and may be propagated either by ſeeds or laying down their branches.

The ſeventh ſort retains its leaves all the year, which renders it valuable. This was formerly preſerved in green-houſes in the winter, ſuppoſing it too tender to live in the open air in England; but now it is generally planted in the full ground, where the plants thrive much better than in pots, and produce plenty of flowers, which they never did when they were more tenderly treated; nor have I found that the plants have ſuffered from ſevere froſts; for thoſe which have been growing in the open air at Chelſea, more than fifty years, have reſiſted the greateſt cold without covering.

This ſort doth not produce ſeeds in England, ſo it is propagated by layers, and alſo from cuttings. If they are propagated by layers, it muſt be done in the beginning of October, when the ſhoots of the ſame year only ſhould be choſen for this purpoſe; for the older branches do not put out roots in leſs than two years, whereas the tender ſhoots will make good roots in one year: theſe muſt be pegged down into the ground, in the ſame manner as is uſually practiſed for other layers, to prevent their riſing. If the ſhoots have two inches of earth over them, it will be better than a greater depth; but then, a little old tanners bark ſhould be ſpread over the ſurface of the ground, to keep out the froſt; for as the plants generally begin flowering about Chriſtmas, ſo at the ſame time they are putting out roots, which being but juſt formed, may be injured by ſevere froſts: theſe layers will have ſtrong roots by the following autumn, when they may be taken from the old plant, and tranſplanted where they are deſigned to remain.

When they are propagated by cuttings, they ſhould be planted in March, in pots filled with good kitchen-garden earth, and plunged into a very moderate hot-bed, obſerving to ſhade them from the ſun in the day-time, and gently water them two or three times a week; and in leſs than two months they will have taken root, when they ſhould be gradually inured to the open air. The following ſummer they may be placed in any part of the garden till Michaelmas, and then they ſhould be turned out of the pots and planted in the full ground, either where they are deſigned to remain, or into a nurſery-bed, to grow a year longer to get ſtrength, before they are placed out for good.

All the varieties of Virgin's Bower are propagated by laying down their branches; for although the ſingle flowers ſometimes produce ſeeds in England, yet as theſe ſeeds, when ſown, generally remain a whole year in the ground before they vegetate, ſo the other being the more expeditious method of increaſing theſe plants, is generally practiſed: but in order to ſucceed, theſe layers ſhould be laid down at a different ſeaſon from the former ſort; for when they are laid in the autumn, their ſhoots are become tough, ſo rarely put out roots under two years; and after lying ſo long in the ground, not one in three of them will have made good roots; ſo that many have ſuppoſed theſe plants were difficult to propagate, but ſince they have altered their ſeaſon of doing it, they have found theſe layers have ſucceeded as well as thoſe of other plants.

The beſt time for laying down the branches is in the beginning of July, ſoon after they have made their firſt ſhoots, for it is theſe young branches of the ſame year, which freely take root; but as theſe are very tender, there ſhould be great care taken not to break them in the operation: therefore thoſe branches from which theſe ſhoots were produced, ſhould be brought down to the ground, and faſtened to prevent their riſing; then the young ſhoots ſhould be laid into the earth, with their tops raiſed upright, three or four inches above ground; and after the layers are placed down, if the ſurface of the ground be covered with moſs, rotten tanners bark, or other decayed mulch, it will prevent the ground from drying, ſo that the layers will not require watering above three or four times, which ſhould not be at leſs than five or ſix days interval; for when theſe layers have too much wet, the tender ſhoots frequently rot; or when the young fibres are newly put out, they are ſo tender, as to periſh by having much wet: therefore where the method here directed is practiſed, the layers will more certainly take root, than by any other yet practiſed.

As moſt of theſe plants have climbing branches, they ſhould be always planted where they may be ſupported, otherwiſe the branches will fall to the ground and appear unſightly; ſo that unleſs they are properly diſpoſed, inſtead of being ornaments to a garden, they will become the reverſe. Where there are arbours or ſeats, with trellis work round them, theſe plants are very proper to train up againſt it; or where any walls or other fences require to be covered from the ſight, theſe plants are very proper for the purpoſe; but they are by no means proper for open borders, nor do they anſwer the expectation, when they are intermixed with ſhrubs; for unleſs their branches have room to extend, they will not be productive of many flowers.

The ſort with double flowers is the moſt beautiful, ſo that ſhould be preferred to thoſe with ſingle flowers, of which a few only ſhould be planted for variety. They are all equally hardy, ſo are ſeldom injured by froſt, excepting in very ſevere winters, when ſometimes the very tender ſhoots are killed; but if theſe are cut off in the ſpring, the ſtems will put out new ſhoots.

The tenth, eleventh, and fifteenth ſorts are alſo very hardy plants, and have climbing branches, ſo may be diſpoſed in the ſame manner as the other: they are alſo propagated by layers, which will ſucceed, if performed at the ſame time, and in the ſame manner as is directed for them.

The other ſorts are natives of the warmeſt parts of America, ſo will not thrive in this country, unleſs they are preſerved in ſtoves; but as theſe are great ramblers and plants of no great beauty, they are ſeldom preſerved in Europe, but in botanic gardens for the ſake of variety. Theſe may be propagated by layers, in the ſame manner as the other ſorts; or may be raiſed from ſeeds, obtained from the countries where they naturally grow; but theſe muſt be treated in the ſame manner as other exotic plants from the ſame country.

CLEOME. Lin. Gen. Plant. 740. Sinapiſtrum. Tourn. Inſt. R. H. 231. tab. 116.

The Characters are,

The flower hath a four-leaved empalement which ſpreads open: it hath four petals which are inclined upward and ſpread open, the two lower being leſs than the other; in the bottom there are three mellous glands which are roundiſh, and are ſeparated by the empalement. It hath ſix or more ſtamina which are incurved, having riſing ſummits fixed to their ſide: it hath a ſingle ſtyle, ſupporting an oblong germen, which is of the ſame length as the ſtamina, and crowned by a thick ſtigma. The germen afterward becomes a long cylindrical pod, ſitting upon the ſtyle, having one cell, opening with two valves, and filled with roundiſh ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliquoſa; the plants of this ſection have in the flowers four long and two ſhort ſtamina, and their ſeeds are included in long pods.

The Species are,

1. Cleome (*Pentaphylla*) floribus gynandris, foliis quinatis caule inermi. Lin. Sp. 938. *Cleome with flowers having male and female parts, five leaves, and ſmooth ſtalks.* Sinapiſtrum Indicum, pentaphyllum flore carneo, minus, non ſpinoſum. H. L.
2. Cleome (*Ornithopodoides*) floribus hexandris, foliis ternatis, foliolis ovati-lanceolatis. Lin. Sp. Plant. 940. *Cleome with flowers having ſix ſtamina, trifoliate leaves, and ſpear-ſhaped lobes.* Sinapiſtrum Orientale, triphyllum, ornithopodii ſiliquis. Tourn. Cor. 17.
3. Cleome (*Luſitanica*) floribus hexandris, foliis ternatis, foliolis lineari-lanceolatis, ſiliquis bivalvibus. *Cleome with flowers having ſix ſtamina, trifoliate leaves, narrow ſpear-ſhaped lobes, and pods having two valves.* Sinapiſtrum Luſitanicum triphyllum, flore rubro. Tourn. Inſt. R. H. 231.
4. Cleome (*Viſcoſa*) floribus dodecandris, foliis quinatis ternatiſque. Flor. Zeyl. 241. *Cleome with flowers having twelve ſtamina, trifoliate and quinquefoliate leaves.* Sinapiſtrum Zeylanicum, triphyllon & pentaphyllon viſcoſum, flavo flore. Mart. Dec. 3.
5. Cleome (*Triphylla*) floribus hexandris, foliis ternatis, foliolo intermedio majori. *Cleome with flowers having ſix ſtamina, and trifoliate leaves, whoſe middle lobe is the largeſt.* Sinapiſtrum Indicum triphyllum, flore carneo non ſpinoſum. H. L.
6. Cleome (*Erucago*) floribus hexandris, foliis ſeptenis, caule ſpinoſo, ſiliquis pendulis. *Cleome with flowers having ſix ſtamina, leaves with ſeven lobes, a prickly ſtalk, and hanging pods.* Sinapiſtrum Ægyptiacum heptaphyllum, flore carneo, majus ſpinoſum. H. L.
7. Cleome (*Spinoſa*) floribus hexandris, foliis quinatis ternatiſque, caule ſpinoſo. *Cleome with flowers having ſix ſtamina, leaves compoſed of five and three lobes, and a prickly ſtalk.* Sinapiſtrum Indicum ſpinoſum, flore carneo, folio trifido vel quinquefido. Houſt. MSS.
8. Cleome (*Monophylla*) floribus hexandris, foliis ſimplicibus, petiolatis ovato-lanceolatis. Flor. Zeyl. 243. *Cleome with ſix ſtamina to the flowers, and ſix leaves, which are ovally ſpear-ſhaped.* Sinapiſtrum Zeylanicum viſcoſum, folio ſolitario, flore flavo, ſiliquâ tenui. Burm. Theſ. 217.

The firſt ſort grows naturally in Aſia, Africa, and America; I have received the ſeeds of it from Aleppo, and the coaſt of Guinea, and in the earth which came from the Weſt-Indies with other plants; this hath come up as a weed. It riſes with an herbaceous ſtalk about a foot high, garniſhed with ſmooth leaves, compoſed of five ſmall leaves or lobes, joining at their baſe to one center, and ſpread out like the fingers of a hand. The leaves on the lower part of the ſtalk ſtand upon long foot-ſtalks, which are gradually ſhortened to the top of the ſtalk, where they almoſt join it: the flowers are produced in looſe ſpikes at the end of the ſtalks and branches; theſe have four petals of a fleſh colour, which ſtand erect, ſpreading from each other; and below theſe are placed the ſtamina and ſtyle, which coaleſce at the bottom, and are ſtretched out beyond the petals, where they ſpread open; after the flower is paſt, the germen which ſits upon the ſtyle, becomes a taper pod, about two inches long, filled with round ſeeds. This is an annual plant, which dies ſoon after the ſeeds are ripe.

The ſecond ſort grows naturally in the Levant, from whence Dr. Tournefort ſent the ſeeds to the royal garden at Paris, and from thence moſt of the botanic gardens in Europe have been furniſhed with it: this riſes with an upright ſtalk about the ſame height as the firſt, garniſhed with leaves compoſed of three ſpear-ſhaped lobes, ſtanding upon ſhort foot-ſtalks; the flowers come out ſingly from the ſide of the ſtalks, and have four red petals, which ſtand in the ſame form as thoſe of the former ſort: theſe are ſucceeded by ſlender pods two inches long, which ſwell in every diviſion, where each ſeed is lodged, ſo as to appear like joints, as thoſe do of the Bird's-foot Trefoil; when the ſeeds are ripe, the whole plant decays. If the ſeeds of this are ſown in autumn the plants will flower in June, and their ſeeds will ripen in Auguſt, but thoſe which are ſown in the ſpring do not flower till July; ſo that unleſs the ſeaſon proves favourable, the ſeeds will not ripen: if the ſeeds of this ſort are permitted to ſcatter, the plants will come up without care, and require only to be thinned and kept clean from weeds, for they will not bear tranſplanting.

The third ſort grows naturally in Portugal and Spain, from whence I have received the ſeeds. This riſes with an herbaceous ſtalk about a foot and half high, ſending out a few ſhort ſide branches, which are garniſhed with leaves compoſed of three narrow lobes, ſtanding upon ſhort foot-ſtalks. The flowers come out ſingly from the ſide of the ſtalks, are of a deep red colour, and are ſucceeded by thick taper pods, filled with round ſeeds. This is an annual plant, which will thrive in the open air, and requires the ſame treatment as the former.

The fourth ſort grows naturally in the iſland of Ceylon, from whence the ſeeds were brought to Holland, where they ſucceeded, and the ſeeds were ſent me by the late Dr. Boerhaave; this riſes near two feet high, ſending out ſeveral ſide branches, garniſhed with leaves, ſome of which have five, and others three roundiſh lobes ſtanding upon ſhort hairy foot-ſtalks. The flowers come out ſingly at the foot-ſtalks of the leaves, they are of a pale yellow, and are ſucceeded by taper pods between two and three inches long, ending in a point, which are full of round ſeeds. The whole plant ſweats out a viſcous clammy juice. This is alſo an annual plant.

The fifth ſort was ſent me from Jamaica by the late Dr. Houſtoun, in the year 1730. This is an annual plant which riſes two feet high, ſending out many ſide branches, garniſhed with leaves, with one large ſpear-ſhaped lobe in the middle, and two very ſmall ones on the ſide; theſe ſit cloſe to the branches. The flowers come out ſingly from the ſide of the branches, upon long foot-ſtalks: theſe have four large fleſh-coloured petals, and ſix long ſtamina, which ſtand out beyond the petals; when the flowers fade, the germen which ſits upon the ſtyle becomes a taper pod four inches long, filled with round ſeeds.

The ſixth ſort was ſent me from Jamaica by the late Dr. Houſtoun, who found it growing naturally there in great plenty. It alſo grows naturally in Egypt. This riſes with a ſtrong thick herbaceous ſtalk two feet and a half high, dividing into many branches, which are garniſhed with leaves compoſed of ſeven long ſpear-ſhaped lobes, joining in a center at their baſe, where they ſit upon a long ſlender foot-ſtalk: juſt below the foot-ſtalk comes out one or two ſhort, thick, yellow ſpines, which are very ſharp. The flowers come out ſingly from the ſide of the branches, forming a long looſe ſpike at their extremities; this ſpike hath ſingle broad leaves, which half ſurround the ſtalks at their baſe, from the boſom of which, come out the foot-ſtalks of the flowers, which are two inches long, each ſuſtaining a large fleſh-coloured flower, whoſe ſtyle and ſtamina are extended two inches beyond the petals. After the flower is paſt, the germen, which ſits upon the ſtyle, becomes a thick taper pod five inches long, which hangs downward, and is filled with round ſeeds. This is alſo an annual plant, which periſhes ſoon after the ſeeds are ripe.

The ſeventh ſort was ſent me from the Havannah in the year 1731, by the late Dr. Houſtoun. This is alſo an annual plant, which riſes near two feet high, branching out on every ſide: the lower leaves are compoſed of five oblong lobes ſtanding upon long foot-ſtalks, but thoſe on the ſtalks and branches have but three lobes, and have ſhort foot-ſtalks: the main ſtalk and alſo the branches, are terminated by looſe ſpikes of purple flowers, each ſitting upon a ſlender foot-ſtalk, at the baſe of which is placed a ſingle oval leaf. The ſtalks are armed with ſlender ſtiff ſpines, which are ſituated juſt under the foot-ſtalks of the leaves; when the flowers fade, the germen becomes a taper pod, two inches long, filled with round ſeeds.

The eighth ſort grows naturally in Ceylon; this is an annual plant, which riſes with an herbaceous ſtalk a foot and half high, garniſhed with long, narrow, ſingle leaves, ſtanding alternately on the ſtalks; from the wings of the leaves come out the foot-ſtalks of the flower, each ſuſtaining a ſingle yellow flower, which is ſucceeded by a very ſlender taper pod.

All theſe plants except the ſecond and third ſorts, are natives of very warm countries, ſo will not thrive in England without artificial heat; therefore their ſeeds muſt be ſown upon a good hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be planted in ſeparate ſmall pots, filled with freſh light earth, and plunged into a freſh hot-bed, obſerving to ſhade them until they have taken freſh root; after which they ſhould have air admitted to them every day in proportion to the warmth of the ſeaſon, and their waterings ſhould be frequently repeated, but not given in too great plenty; when the plants have filled theſe ſmall pots with their roots, they ſhould be put into larger, and plunged again into a hot-bed to bring them forward; and in July, when they are too tall to remain longer in the hot-bed, they ſhould be removed into an airy glaſs caſe, where they may be ſcreened from cold and wet, but in warm weather may enjoy the free air. With this management the plants will flower ſoon after, and perfect their ſeeds in autumn. The ſecond and third ſorts may be ſown in the open borders of the garden, where they are deſigned to remain, for they do not require any artificial warmth.

CLEONIA, Portugal Self-heal.

The CHARACTERS are,

It hath a bilabiated empalement of one leaf, which is tubulous and angular; the upper lip is broad, plain, and indented in three parts; the under is ſhort and divided into two. The flower is of the grinning kind, with one petal; the upper lip is erect and divided into two parts, the lower is trifid, the middle ſegment having two lobes, the two lateral ſpread aſunder; it hath four ſtamina, the two lower being the longeſt, whoſe outer top of their ſummits form a croſs. It hath four germen, ſupporting a ſlender ſtyle with four ſtigma, having four equal briſtles; the germen afterward become four ſeeds, incloſed in the hairy empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, the flower having two long and two ſhort ſtamina, and are ſucceeded by naked ſeeds filling in the empalement.

This plant grows naturally in Spain and Portugal; it is annual, periſhing ſoon after it has ripened its ſeeds. It was formerly ranged under the genus of Bugula, Tournefort afterward titled it Clinopodium, and father Barrelier placed it with the Prunella, to which genus it is nearly related.

It is propagated by ſeeds, which, when ſown in the autumn the plants will come up the following ſpring: but the ſeeds which are ſown in the ſpring, frequently lie in the ground till the following autumn, and ſometimes till the next ſpring before they vegetate. When the plants come up and are fit to tranſplant, a few of them may be planted into a border where they may remain to produce their flowers and ſeeds, as they require but little culture; ſo a few plants may be allowed to have place in ſmall gardens, where they will not take much room.

CLETHRA. Gron. Fl. Virg. 43. Lin. Gen. Plant. 489.

The CHARACTERS are;

The flower hath a permanent empalement of one leaf, which is cut into five parts; it hath five oblong petals, which are longer than the empalement; it hath ten ſtamina which are as long as the petals, and are terminated by oblong erect ſummits; in the center is ſituated a roundiſh germen ſupporting a permanent erect ſtyle, crowned by a trifid ſtigma. The germen afterward becomes a roundiſh capſule incloſed by the empalement, having three cells, which are full of angular ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, the flowers having ten ſtamina, and one ſtyle.

We know but one SPECIES of this genus at preſent, viz.

CLETHRA (*Alnifolia*) Gron. Virg. 47. *There is no Engliſh title to this plant*, it is the Alnifolia Americana ſerrata, floribus pentapetalis albis in ſpicam diſpoſitis. Pluk. Alm. 18. *American Shrub with an Alder ſawed leaf, and white five-leaved flowers, diſpoſed in a ſpike.*

This ſhrub is a native of Virginia and Carolina, where it grows in moiſt places, and near the ſides of rivulets, riſing to the height of eight or ten feet, but in this country it rarely riſes to half that height: the leaves are in ſhape like thoſe of the Alder-tree, but are longer; theſe are placed alternately upon the branches: the flowers are produced at the extremity of the branches, in cloſe ſpikes: they are compoſed of five leaves, are white, and have ten ſtamina in each, which are nearly of the ſame length with the petals, this plant flowers in July, and when the autumn proves favourable, there are often ſome ſpikes of flowers again in October.

This is hardy enough to bear the open air in England, and is one of the moſt beautiful ſhrubs at the ſeaſon of its flowering; which is very little later than in its native country, being commonly in flower here by the beginning of July; and if the ſeaſon is not very hot, there will be part of the ſpikes in beauty till the beginning of Auguſt; and as moſt of the branches are terminated with theſe ſpikes of flowers, ſo when the ſhrubs are ſtrong, they make a fine appearance at that ſeaſon.

This will thrive much better in moiſt land than in dry ground, and requires a ſheltered ſituation, where it may be defended from ſtrong winds, which frequently break off the branches, where they are too much expoſed to its violence. It is propagated by layers, but they are generally two years before they get root, ſo that at preſent it is rare in England. The fineſt ſhrubs of this kind, which I have yet ſeen, are in the curious garden of his grace the late duke of Argyle, at Whitton near Hounſlow, where they thrive as well as in their native country. They may alſo be propagated by ſuckers, which are ſent out from their roots; if theſe are carefully taken off with fibres in the autumn, and planted into a nurſery-bed, they will be ſtrong enough in two years to tranſplant where they are to remain.

It may alſo be propagated by ſeeds, which muſt be procured from the countries where it grows naturally, for the ſeeds are not perfected in England. But as theſe ſeldom arrive here till ſpring, ſo when they are ſown at that ſeaſon, the plants will not come up till the following ſpring. Therefore the ſeeds ſhould be ſown in pots, and placed in a ſhady ſituation till autumn, then placed under a frame in winter; the plants will come up the next ſpring, and in autumn may be tranſplanted into a nurſery-bed, to get ſtrength before they are placed to remain for good.

CLIFFORTIA. Lin. Gen. Plant. 1004.

The name was given to this genus of plants by Dr. Linnæus, in honour of Mr. George Clifford of Amſterdam; a great collector of plants, and a patron of botaniſts, who has printed a folio book of the plants in his garden, with ſeveral copper-plates, exhibiting the figures of many of the moſt curious plants. We have no Engliſh name for it.

The CHARACTERS are;

It hath male and female flowers in different plants: the male flowers have a ſpreading empalement, compoſed of three ſmall, oval, concave leaves. It hath no petals, but a great number of hairy upright ſtamina, which are the length of the empalement, terminated by compreſſed, oblong, twin ſummits. The female flowers have a permanent empalement, compoſed of three leaves which are equal, ſitting upon the germen; theſe have no petals, but the oblong germen which is ſituated below the empalement, ſupports two long, ſlender, feathered ſtyles, terminated by a ſingle ſtigma; the germen afterward becomes an oblong taper capſule, with two cells crowned by the empalement, including one narrow taper ſeed.

This genus of plants is ranged in the tenth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Polyandria; the plants of this ſection and claſs have male and female flowers on different plants, and the male flowers have a great number of ſtamina.

The SPECIES are,

1. CLIFFORTIA (*Ilicifolio*) foliis ſubcordatis, dentatis. Lin. Sp. Plant. 1308. *Cliffortia with heart-ſhaped indented leaves.* Arbuſcula Afr. folio acuto ilicis caulem amplexo rigido. Boerh. Ind. alt. 2.
2. CLIFFORTIA (*Trifoliata*) foliis ternatis, intermedio tridentato. Prod. Leyd. 253. *Three-leaved Cliffortia, whoſe middle leaf is cut in three parts.* Myrica foliis ternatis, intermediis cuneiformibus tridentatis. Hort. Cliff. 456.
3. CLIFFORTIA (*Ruſcifolia*) foliis lanceolatis, integerrimis. Hort. Cliff. 463. *Cliffortia with ſpear-ſhaped leaves which are entire.* Frutex Æthiopicus conifer, fructu parvo, ſparſim intra folia ruſci, ſeminibus cylindraceis.

The firſt ſort grows naturally at the Cape of Good Hope, but hath been long cultivated in many of the Engliſh gardens; however it was not reduced to any genus, till Dr. Linnæus eſtabliſhed this, and gave it the title. By ſome former writers it was called Camphorata, to which genus it had no relation.

It riſes with a weak ſhrubby ſtalk four or five feet high, ſending out many diffuſed branches, which ſpread out on every ſide, requiring ſome ſupport: theſe are garniſhed with leaves, which are heart-ſhaped at their baſe, but broad at their ends, where they are ſharply indented. They are very ſtiff, of a grayiſh colour, and cloſely embrace the ſtalks with their baſe, and are placed alternate on the branches; from the boſom of theſe ariſe a ſingle flower, ſitting cloſe to the branch, having no foot-ſtalk. Before the empalement is ſpread open, it forms a bud, in ſhape and ſize of thoſe of the Caper; this empalement is compoſed of three green leaves, which afterwards ſpread open, and then the numerous ſtamina appear ſtanding erect; theſe, as alſo the inner ſurface of the empalement, are of a yellowiſh green colour. The flowers appear in June, July, and Auguſt, but the leaves continue in verdure through the year.

All the plants which I have ſeen of this ſort, either in the Engliſh or Dutch gardens, were male, nor have I heard of any female plants being in any of the European gardens.

This plant is eaſily propagated by cuttings, which may be planted in any of the ſummer months; if theſe are planted in ſmall pots filled with light earth, and plunged into a very moderate hot-bed they will ſoon take root, provided they are ſcreened from the ſun and duly watered; when they have taken root, they muſt be gradually inured to bear the open air, to which they ſhould be expoſed, to prevent their drawing up weak: therefore they ſhould be placed abroad till they have obtained ſome ſtrength, then they may be each tranſplanted into a ſeparate ſmall pot, and placed in the ſhade until they have taken freſh root; after which they may be placed with other of the hardy kinds of exotic plants in a ſheltered ſituation till October, when they ſhould be removed into the greenhouſe, or placed under a common hot-bed frame, where they may be ſcreened from the hard froſt, but enjoy the free air at all times when the weather is mild.

When the plants advance in height, their ſtems and branches muſt be ſupported, otherwiſe they will trail upon the ground. In ſummer they muſt be placed in the open air, with Myrtles and other hardy green-houſe plants; and in winter the plants may be treated in the ſame manner as thoſe, but muſt have little water in winter. This plant has endured the cold of our ordinary winters, when planted near a ſouth-weſt wall without covering, but in ſevere winters they are always deſtroyed.

The ſecond ſort is a native of the ſame country as the firſt; this hath very ſlender ligneous ſtalks, which muſt be ſupported, otherwiſe they will fall to the ground. Theſe ſend out ſlender branches on every ſide, which are cloſely garniſhed with trifoliate leaves ſtanding cloſe to the branches; the middle lobes of theſe are much larger than the two ſide, and are indented in three parts. The flowers of this come out from the boſom of the leaves, having very ſhort foot-ſtalks, and are ſhaped like thoſe of the firſt, but are ſmaller; theſe appear in July and Auguſt. Of this ſort we have only male plants in the Engliſh gardens, which can only be propagated by layers; and as theſe are two years before they take root, the plants are at preſent very rare in England. This ſort requires the ſame management as the firſt, and is equally hardy, but muſt not be over watered in winter. The leaves of this ſort continue green all the year, and being ſingularly ſhaped, they make a variety in the green-houſe during the winter ſeaſon.

The third ſort riſes with a weak ſhrubby ſtalk about four feet high, ſending out lateral branches, which are covered with a whitiſh bark, and are garniſhed with leaves, placed in cluſters without order; theſe are ſtiff, of the conſiſtence and colour of the Butchers Broom, but are narrower, and run out to a longer point. Between theſe cluſters of leaves the flowers come out in looſe bunches, theſe have a great number of yellowiſh ſtamina, included in a three-leaved empalement. We have only the male plant of this ſort, which is very difficult to propagate, ſo is very rare in Europe at preſent.

This plant is tenderer than either of the former ſorts, ſo ſhould be placed in a warm green-houſe in winter, and during that ſeaſon, they muſt have but little water. In the ſummer they may be expoſed to the open air in a ſheltered ſituation, but they ſhould not remain abroad too late in the autumn; for if there ſhould be much rain at that ſeaſon, it would endanger theſe plants if they are expoſed to it.

CLIMATE [of Κλίμα, *Gr.* an inclination,] is a part of the ſurface of the earth bounded by two circles parallel to the equator; ſo that the longeſt day in that parallel, neareſt to the pole, exceeds the longeſt day in that parallel neareſt to the equator by ſome certain ſpace of time, viz. half an hour, till you come to places ſituate nearly under the arctic circle; and a whole hour, or even ſeveral days when you go beyond it.

The antient Greek geographers reckoned only ſeven climates from the equator towards the north pole, and denominated them from ſome noted place, through which the middle parallel of the climate paſſed; but the moderns reckon up twenty-four.

The beginning of the climate is the parallel circle, wherein the day is the ſhorteſt.

The end of the climate is that wherein the day is the longeſt.

The climates therefore are reckoned from the equator to the pole; and are ſo many bands or zones, terminated by lines parallel to the equator; though in ſtrictneſs there are ſeveral climates in the breadth of one zone.

Each climate only differs from its contiguous ones, in that the longeſt day in ſummer is longer or ſhorter by half an hour in one place than the other.

As the climates commence from the equator, the firſt climate at its beginning has its longeſt day preciſely twelve hours long; at its end twelve hours and a half; the ſecond, which begins where the firſt ends, viz. at twelve hours and a half, ends at thirteen hours: and ſo of the reſt, as far as the polar circles.

Here what geographers call hour-climates terminate, and month-climates commence.

As an hour-climate is a ſpace compriſed between two parallels of the equator, in the firſt of which the longeſt day exceeds that in the latter by half an hour; ſo the month-climate is a ſpace between two circles parallel to the polar circles, whoſe longeſt day is longer or ſhorter than that of its contiguous one by a month, or thirty days.

The antients, who confined the climates to what they imagined the habitable part of the earth, only allowed of ſeven, as had been ſaid: the firſt they made to paſs through Meroe, the ſecond through Sienna, the third through Alexandria, the fourth through Rhodes, the fifth through Rome, the ſixth through Pontus, and the ſeventh through the mouth of the Boryſthenes.

The moderns, who have ſailed farther towards the poles, make thirty climates on each ſide; and becauſe the obliquity of the ſphere makes a little difference in the length of the longeſt day, ſome of them make the difference of the climate but a quarter of an hour inſtead of half an hour.

The term climate is vulgarly beſtowed on any country or region differing from another, either in reſpect of the ſeaſons, the quality of the ſoil, or even the manners of the inhabitants, without any regard to the length of the longeſt day.

CLINOPODIUM. Lin. Gen. Plant. 644. Tourn. Inſt. R. H. 194. tab. 92. Field Baſil.

The CHARACTERS are,

It hath an involucrum cut into many parts, is the length of the empalement, upon which the whorls ſit. The empalement is of one leaf, with a cylindrical tube, which is divided into two lips; the upper lip is broad, trifid, acute, and reflexed; the under lip is cut into two narrow ſegments, which turn inward. The flower is of the lip kind, with a ſhort tube enlarging to the mouth; the upper lip is erect, concave, and indented at the top, which is obtuſe; the under lip is trifid and obtuſe, the middle ſegment being broad and indented. It hath four ſtamina under the upper lip, two of which are ſhorter than the other, terminated by roundiſh ſummits; in the center is ſituated the quadripartite germen, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by a ſingle compreſſed ſtigma. The germen afterward become four oval ſeeds ſhut up in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia. The flowers of this claſs and ſection, have two long, and two ſhort ſtamina, which are ſucceeded by four naked ſeeds.

The SPECIES are,

1. CLINOPODIUM (*Vulgare*) capitulis ſubrotundis, hiſpidis, bracteis ſetaceis. Lin. Sp. Plant. 587. *Field Baſil with roundiſh prickly heads, and briſtly bractea.* Clinopodium Origano ſimile, elatius, majore flore. C. B. P. 225. *Common Engliſh Field Baſil.*
2. CLINOPODIUM (*Incanum*) foliis ſubtus tomentoſis, verticillis explanatis, bracteis lanceolatis. Lin. Sp. Plant. 588. *Field Baſil with leaves which are woolly on the under ſide, broad plain whorls, and ſpear-ſhaped bractea.* Clinopodium menthæ folio incanum, & odoratum. Hort. Elth. 87.
3. CLINOPODIUM (*Rugoſum*) foliis rugoſis, capitulis axillaribus, pedunculatis, explanatis, radiatis. Lin. Sp. Plant. 588. *Field Baſil with rough leaves, plain heads growing on the ſides of the ſtalks, which have foot-ſtalks, and are radiated.* Clinopodium rugoſum, capitulis ſcabioſæ. Hort. Elth. 88.
4. CLINOPODIUM (*Humile*) humile ramoſum, foliis rugoſioribus, capitulis explanatis. *Low branching Field Baſil with rougher leaves, and plain heads.* Clinopodium Americanum humile, foliis rugoſioribus. Dale.

5. **Clinopodium** (*Carolinianum*) caule erecto, non ramoſo, foliis ſubtus villoſis, verticillis paucioribus, bracteis calyce longioribus. *Field Baſil with an upright unbranching ſtalk, leaves hairy on their under ſide, fewer whorls, and bractea longer than the empalement.* Clinopodium Americanum, erectum, non ramoſum foliis longioribus, internodiis longiſſimis. Dale.

6. **Clinopodium** (*Ægyptiacum*) foliis ovatis rugoſis, verticillis omnibus diſtantibus, i. e. *Field Baſil with oval rough leaves, and the whorls of flowers ſtanding at a great diſtance.* Clinopodium Ægyptiacum, vulgari ſimile. Dill. *Ægyptian Field Baſil like the common.*

The firſt ſort grows naturally by the ſide of hedges and in thickets, in many parts of England; this hath a perennial fibrous root, which ſends up ſeveral ſtiff ſquare ſtalks a foot and a half high, from which come out a few lateral branches toward the top, garniſhed with oval hairy leaves, placed oppoſite; at the top of the ſtalks the flowers come out in round whorls, or heads; one of theſe terminate the ſtalk, and there is generally another which ſurrounds the ſtalk at the joint immediately below it. The flowers are ſometimes purple, at others white, for they vary from one colour to the other, when they are propagated by ſeeds, ſo that both colours are found naturally in the fields. The whorls (or heads) grow very cloſe, and each foot-ſtalk ſuſtains ſeveral flowers; each flower hath a tubular empalement, ending in five ſharp points, which ſtand erect; at the baſe of the empalement ſtand two briſtly ſpines, which Linnæus terms the bractea; theſe ſtand almoſt horizontal under the empalement. The flower is of the labiated, or lip kind, according to Tournefort, Ray, &c. which is now ſtyled ringent, or grinning, from the appearance which the upper part has to the mouth, or chaps of animals. The upper lip is broad and trifid, but the under is cut into two narrow ſegments; each flower is ſucceeded by four naked ſeeds, ſitting at the bottom of the empalement. This flowers in June.

The ſecond ſort grows naturally in Penſylvania and Carolina, from both of theſe countries I have frequently received the ſeeds; this hath a perennial root, which ſends up many ſquare ſtalks about two feet high, which put out a few ſhort ſide branches toward the upper part, garniſhed with oblong oval leaves, about the ſize of thoſe of Water Mint, ſtanding oppoſite, cloſe to the ſtalk; they are hoary, and ſoft to the touch, and have a ſtrong odour, between that of Marjoram and Baſil. The upper ſurface of the leaves is of a pale green, but their under ſide is hoary and woolly, they are ſlightly indented on their edges. The flowers grow in flat ſmooth whorls round the ſtalks, each ſtalk hath generally three of theſe whorls, the upper which terminates the ſtalk being ſmaller, the other two increaſing, ſo that the lower is the greateſt. The flowers are of a pale purple colour, and ſhaped like thoſe of the firſt ſort, but the ſtamina of this ſtands out beyond the petal, and the bractea at the baſe of the empalement are large, ſpear-ſhaped, and indented on their ſides. This plant is called Snake-weed in ſome parts of America, ſuppoſing it a remedy for the bite of rattle ſnakes. This flowers in July in England.

The third ſort grows naturally in Carolina, from whence the ſeeds were ſent me by the late Dr. Dale: this hath a perennial root, which ſends up ſeveral ſquare ſtalks, which are cloſely covered with browniſh hairs; theſe riſe between two and three feet high, garniſhed with leaves which are very unequal in their ſize, thoſe at the bottom, and alſo toward the top, being above three inches long, and one inch and a quarter broad, whereas thoſe in other parts of the ſtalk are not half ſo large; they are rough on their upper ſide, hairy below, and ſawed on their edges, ſtanding oppoſite: all the lower part of the ſtalk, but immediately below the foot-ſtalks of the flower-heads, there are three large leaves ſtanding round the ſtalks; between theſe ariſe two ſlender hairy foot-ſtalks, about three inches long, one on each ſide the ſtalk; theſe ſuſtain ſmall heads of flowers, ſhaped like thoſe of the ſcabious; they are white, ſhaped like thoſe of the other, but ſmaller; the bractea immediately under the empalement, ſpread out like rays. This plant flowers in September in this country, but never ripens its ſeeds here.

The ſeeds of the fourth ſort were ſent me from Carolina, by the late Dr. Dale; this hath ſome appearance of our common ſort, but the ſtalks do not grow more than half ſo high, and divide into many long ſide branches; the leaves are ſmaller and rougher, and the whorls of flowers are produced half the length of the branches, whereas the common ſort hath rarely more than two; the bractea at the baſe of the empalement is alſo much longer. This flowers in June and July, and hath a perennial root.

The fifth ſort was ſent me by the late Dr. Dale, from Carolina; this hath a perennial root, which ſends up ſtrait hairy ſtalks, almoſt round; the joints of theſe are four or five inches aſunder, at each of theſe come out two oblong leaves, hairy on their under ſide, ſtanding upon ſhort foot-ſtalks; at the bottom of theſe come out on each ſide a ſlender branch, half an inch long, having two or four ſmall leaves, ſhaped like the other. The flowers are produced in ſmall whorls, ſtanding thinly; theſe are white, and the bractea are longer than the empalement. This flowers in Auguſt.

The ſixth ſort is a native of Egypt, from whence the ſeeds were ſent to Europe, and the plants have for ſome years paſt grown in many curious gardens. It hath a perennial root; the ſtalks riſe a foot and an half high, garniſhed with oval leaves, having many tranſverſe deep furrows, of a dark green colour, placed oppoſite, at about five or ſix inches aſunder. There are commonly two or four ſide branches from the main ſtem, produced toward the bottom; and the whorls of flowers are produced at every joint toward the upper part of the ſtalks: theſe are pretty large and hairy. The flowers are ſomewhat larger than thoſe of the common Field Baſil, and are of a deeper colour, ſtretching a little more out of the empalement. The leaves of this have at firſt ſight much the ſame appearance; but when they are obſerved with attention, the difference is ſoon obſerved between the two ſorts: but the greateſt difference is in the leaves and whorls of flowers being placed at a greater diſtance, and the ſtalks growing ſparſedly in this ſpecies; nor do the plants continue ſo long as thoſe of the common ſort.

This ſort flowers in June, commonly a fortnight or three weeks before the common Field Baſil, and the ſeeds ripen in September; which, if permitted to ſcatter, the plants will come up in autumn; and if the winter proves favourable, they will live in the open air, provided they grow on a dry ſoil; but in moiſt ground they are frequently deſtroyed, eſpecially when the plants are young.

This plant approaches near to the Clinopodium Orientale Origani folio, flore minimo. Tour. Corol. 12. But by comparing this with a ſpecimen of that ſort from the Paris garden, I find the leaves of that are ſmoother, and placed much nearer together on the ſtalks than thoſe of this ſort; the flowers are ſmaller, ſo that it may be deemed a diſtinct ſpecies, as theſe differences are permanent, and do not alter in any of the plants which ariſe from the ſeeds.

Theſe plants may be propagated by ſeeds, and alſo by parting their roots; the latter is generally practiſed in England, becauſe few of the ſorts perfect their ſeeds here. The beſt time to tranſplant and part their roots is in autumn, that they may take root before winter. If theſe are planted in a dry ſoil, they are all, except the third ſort, hardy enough to thrive in the open air in England, and require no other care but to keep them clean from weeds, and every other year they may be tranſplanted and parted. The third ſort muſt be planted in pots, and in winter ſheltered under a frame, where the plants may enjoy the free air in mild weather, but ſcreened from froſt, otherwiſe they will not live in this country.

CLITORIA. Lin. Gen. Plant. 796. Ternatea. Tourn. Act. Reg. 1706. Clitorius. Dill. Hort. Elth. 76. We have no Engliſh title for this plant.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is tubular, erect, and indented in five parts at the top. The flower is of the butterfly kind, having a large ſpreading ſtandard, which is erect, and indented at the top; the two wings are oblong, obtuſe, and ſhorter than the ſtandard, which is cloſed. The keel is ſhorter than the wings; it is roundiſh and hooked; it hath ten ſtamina, nine of which are joined, and one ſtands ſeparate, which are terminated by ſingle ſummits. In the center is ſituated an oblong germen, ſupporting a riſing ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a long, narrow, compreſſed pod, with one cell, opening with two valves, incloſing ſeveral kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria; the flowers of this ſection have ten ſtamina, which compoſe two bodies.

The SPECIES are,

1. CLITORIA (*Ternatea*) foliis pinnatis. Hort. Cliff. 360. *Clitorea with winged leaves.* Ternatea flore ſimplici cæruleo. Tourn. Acad. Reg. Sc. 1706.
2. CLITOREA (*Braſiliana*) foliis ternatis, calycibus campanulatis ſolitariis. Hort. Upſal. 215. *Clitoria with trifoliate leaves, and a ſingle flower with a bell-ſhaped empalement.* Planta leguminoſa Braſiliana, Phaſeoli flore, flore purpureo maximo. Breyn. Cent. 78. tab. 32.
3. CLITORIA (*Virginiana*) foliis ternatis, calycibus campanulatis ſubgeminis. Flor. Virg. 83. *Three-leaved Clitoria with two flowers joined, whoſe empalements are bell-ſhaped.* Clitorius trifolius flore minore cæruleo. Hort. Elth. 90. tab. 76.
4. CLITORIA (*Mariana*) foliis ternatis, calycibus cylindricis. Lin. Sp. Plant. 753. *Clitoria with trifoliate leaves, and cylindrical empalements to the flowers.* Clitorius Marianus trifolius ſubtus glaucis. Pet. Hort. Sicc. 243.

The firſt ſort grows naturally in India; the ſeeds of this were firſt brought to Europe from Ternate, one of the Molucca Iſlands, and this induced Dr. Tournefort to give the title of Ternatea to this genus. There is a variety of this with white flowers, and another with large blue flowers, which make a fine appearance. The ſeeds which I received of the latter, produced all the plants with very double flowers, without the leaſt variation; but in cold ſeaſons the plants do not produce any pods here.

This riſes with a twining herbaceous ſtalk to the height of four or five feet, in the ſame manner as the Kidney-bean, and requires the like ſupport; for in the places where it grows naturally, it twiſts itſelf about the neighbouring plants; the ſtalks are garniſhed with winged leaves, compoſed of two or three pair of lobes, terminated by an odd one; theſe are of a beautiful green, and are placed alternate on the ſtalks; from the appendages of the leaves, come out the foot-ſtalks of the flower; each of theſe is encompaſſed by two very fine leaves about the middle, where they are bent, ſuſtaining a very large, gaping, beautiful flower, whoſe bottom part ſeems as if growing to the top.

The flowers have a green membranaceous empalement, which is cut into five parts. The ſtandard of the flowers is large, and is ſpread open very wide; and the flowers are of ſo deep a blue colour, as to ſtain paper, after having been many years dried, almoſt as blue as indigo; theſe flowers are ſucceeded by long ſlender pods, containing ſeveral kidney-ſhaped ſeeds.

The ſecond ſort grows naturally in the Braſils, from whence theſe ſeeds were brought to Europe. This hath a twining ſtalk like the former, which riſes five or ſix feet high, garniſhed at each joint with one trifoliate leaf, ſtanding upon a long foot-ſtalk. The flowers come out ſingly from the foot-ſtalk of the leaves, ſtanding upon pretty long foot-ſtalks, which are encompaſſed about the middle with two ſmall oval leaves; the flowers are very large, the ſtandard being much broader than that of the firſt ſort, and the two wings are larger; the flowers are of a fine blue colour, ſo make a fine appearance. The flowers appear in July, and in warm ſeaſons the ſeeds will ripen in autumn, ſoon after which the plants decay.

There is one with a double flower of this ſort, which I raiſed in the Chelſea garden ſome years paſt, from ſeeds ſent me from India; but the plants did not produce ſeeds here, and being annual, the ſort was loſt. The flowers of this were very beautiful.

The ſeeds of the third ſort were ſent me from the Bahama Iſlands; this ſends out from the root two or three ſlender twining ſtalks, which riſe to the height of ſix or ſeven feet, garniſhed at each joint with one trifoliate leaf, whoſe lobes are oblong and pointed. At the oppoſite ſide of the ſtalk, the foot-ſtalk of the flower ariſes, which is little more than an inch long, naked, and ſuſtains a ſingle flower, which is of a purple colour within, but of a greeniſh white on the outſide, not half ſo large as either of the former: theſe flowers are each ſucceeded by long, ſlender, compreſſed pods, ending in a point, which contain one row of roundiſh kidney-ſhaped ſeeds. This ſort flowers in July and Auguſt, and the ſeeds ripen in autumn.

The ſeeds of the fourth ſort were ſent me from Carolina, where the plants grow naturally. This riſes with a twining weak ſtalk about five feet high, garniſhed with trifoliate leaves like the former, whoſe lobes are narrower, and of a grayiſh colour on their under ſide; the flowers come out by pairs on the foot-ſtalks; their empalements are cylindrical. The flowers are ſmall, and of a pale blue colour within, but of a dirty white on the outſide. This flowers in Auguſt, but rarely ripens any ſeeds in England.

All theſe ſorts are annual with us in England, ſo that unleſs the ſeeds ripen, the ſpecies are loſt; and as the two ſorts with double flowers have not formed any pods in this country, ſo far as I have been able to learn, therefore the ſeeds of theſe muſt be procured from the countries where they naturally grow. Indeed theſe are ſuppoſed to be only varieties, which accidentally ariſe from the ſingle. If this be true, I cannot account for the ſucceſs of thoſe plants which grew at Chelſea, for they were all of the ſame double kind, without the leaſt variation; and this was not from a ſingle experiment, but in three different years when I received the ſeeds, the plants did all of them produce double flowers.

The ſeeds of theſe plants muſt be ſown upon a good hot-bed early in the ſpring; and when the plants are two inches high, they ſhould be carefully taken up, and each planted in a ſmall pot filled with light freſh earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them till they have taken freſh root, and refreſh them with water as they may require it. After they are well rooted in the pots, they muſt have air every day in proportion to the warmth of the ſeaſon, to prevent their drawing up weak; their waterings ſhould be repeated two or three times a week, but they ſhould not have too much at each time. As theſe plants have climbing ſtalks, they will ſoon grow too tall to remain under common frames, therefore they muſt then be removed into the ſtove, and plunged into the bark-bed; but if their roots have filled the pots, they ſhould be removed into larger, and afterward they muſt be treated in the ſame manner as other plants from the ſame countries.

CLUSIA. Lin. Gen. Plant. 577. Plum. Nov. Gen. 20. tab. 20. The Balſam-tree.

The CHARACTERS are,

It hath an imbricated empalement, compoſed of roundiſh concave leaves which ſpread open; it hath five or ſix large, roundiſh, concave, ſpreading petals. In the bottom is ſituated a globular nectarium, including the germen, which is pervious at the top, from which place the ſtigma ariſes.

It hath a great number of ſtamina, which are ſhorter than the petals, terminated by ſingle ſummits. The oblong oval germen is terminated by a plain ſtar-like ſtigma, with ſix obtuſe indentures. The germen afterward becomes an oval capſule, with ſix furrows, and ſix cells, opening with ſix valves, which ſpread in form of a ſtar, including many angular ſeeds fixed to a column, ſurrounded with pulp.

This genus of plants is ranged in the firſt ſection of Linnæus's twenty-third claſs, intitled Polygamia Monœcia, having male, female, and hermaphrodite flowers on the ſame plant.

The Species are,

1. Clusia (*Flava*) foliis aveniis corollis tetrapetalis. Jacq. Amer. 34. *Cluſia whoſe leaves have no veins, and the flower has four petals.* Terebinthus folio ſingulari, non alato, rotundo, ſucculento flore pallidè luteo. Sloan. Hiſt. Jam. 2. p. 97. *Commonly called Balſam-tree in America.*
2. Clusia (*Venoſa*) foliis venoſis. Lin. Sp. Plant. 510. *Cluſia with veined leaves.* Cluſia flore roſeo minor, fructu flaveſcente. Plum. Nov. Gen. 2.

There are three varieties of the firſt ſort, which differ in the ſize and colour of their flowers and fruit; one hath a white flower and ſcarlet fruit, another hath a Roſe flower and a greeniſh fruit, and a third hath a yellow fruit: but theſe are ſuppoſed to be only ſeminal variations, though Plumier has enumerated them as diſtinct ſpecies; but as the plants have not flowered in England, I can give no particular account of their difference: the ſingular beauty of the leaves of this plant, renders it worthy of a place in every collection of rare plants.

The firſt ſort is pretty common in the Britiſh Iſlands of America, where the trees grow to the height of twenty feet, and ſhoot out many branches on every ſide, garniſhed with thick, round, ſucculent leaves, placed oppoſite. The flowers are produced at the ends of the branches, each having a thick ſucculent cover: theſe are of different colours in different plants, ſome being red, others yellow, ſome white, and ſome green. After the flowers are paſt, they are ſucceeded by oval fruit, which are alſo of different colours in different plants: from every part of theſe trees there exſudes a ſort of turpentine, which is called in the Weſt Indies Hog-gum; becauſe they ſay, that, when any of the wild hogs are wounded they repair to theſe trees, and rub their wounded parts againſt the ſtems of them, till they have anointed themſelves with this turpentine, which heals their wounds. The turpentine of theſe trees is alſo greatly recommended for the cure of ſciaticas, by ſpreading it on a cloth, and applying it as a plaſter to the part affected.

The plants are at preſent very rare in Europe: there were ſome years ago ſome fine plants in the garden of Mr. Parker, near Croyden in Surry; theſe were brought over, growing in tubs of earth from Barbadoes, which is the beſt method of procuring them; for the ſeeds ſeldom ſucceed, and the young plants grow ſo ſlowly, as not to make any figure in ſome years; but in the bringing over the plants, great care ſhould be had, that they do not receive much wet; for as theſe plants have very ſucculent ſtems, moiſture will cauſe them to rot.

The plants are tender, ſo they muſt be conſtantly kept in the ſtove, otherwiſe they will not live through the winter in England; they muſt alſo be watered very ſparingly, eſpecially in winter, for they naturally grow in thoſe parts of the iſlands, where it ſeldom rains, therefore they cannot bear much moiſture.

They may be propagated by cuttings, which muſt be laid to dry when they are cut off from the plants for a fortnight or three weeks, that the wounded part may be healed over, otherwiſe they will rot. When the cuttings are planted, the pots ſhould be plunged into a hot-bed of tanners bark, and now and then gently refreſhed with water: the beſt time for planting theſe cuttings is in June or July, that they may be well rooted before the cold weather comes on in autumn. In winter theſe plants may be placed upon ſtands in the dry ſtove; but if in ſummer they are plunged into the tan-bed, they will make great progreſs, and their leaves will be large, in which conſiſts the great beauty of theſe plants.

The ſecond ſort was diſcovered by the late Dr. Houſtoun, growing naturally at Campeachy, from whence he ſent me ſome dried ſamples and ſeeds: this hath very large oval ſpear-ſhaped leaves, ending in points, which are placed alternate on the branches, and have ſeveral ribs, which go off from the midrib alternate, riſing upward to the ſide of the leaves; and alſo a great number of ſmall veins, running horizontally between theſe ribs. The borders of the leaves are ſawed, and their under ſides are of a ſhining brown colour. The branches are covered with a woolly down, and the flowers are produced in looſe ſpikes at the end of the ſhoots; theſe are ſmaller than thoſe of the former ſort, and are of a Roſe colour. This tree riſes to the height of twenty feet; it is propagated by ſeeds, which muſt be obtained from the countries where the trees naturally grow, for there can be little hopes of obtaining any of the ſeeds in Europe. The plants are tender, ſo muſt be placed in the tan-bed of the bark-ſtove, otherwiſe they will not thrive in this country; and they muſt be treated in the ſame manner as is directed for other tender plants from the ſame countries.

CLUTIA. This genus of plants was conſtituted by the learned Dr. Boerhaave, profeſſor of botany in the univerſity of Leyden, in honour of Augerius Clute, a curious botaniſt.

The Characters are,

It is male and female in different plants. The male flowers have a large ſpreading empalement, compoſed of five oval concave leaves; they have five heart-ſhaped petals, which are ſhorter than the empalement, and ſpread open. They have five exterior nectariums, which are ſituated in a circle at the bottom of the petals; and five interior, which are ſituated within the other, having ſmall apices with a mellous liquor, and five ſtamina ſituated in the middle of the ſtyle, which ſpread horizontally, terminated by roundiſh ſummits: theſe have no germen, but a long truncated ſtyle in the middle of the ſtamina. The female flowers have permanent empalements, and petals like thoſe of the male; theſe have five double exterior nectariums, but no interior; they have a roundiſh germen, ſupporting three bifid reflexed ſtyles the length of the petals, crowned by obtuſe ſtigma: the germen afterward becomes a globular capſule, with ſix furrows, and three cells, each containing a ſingle ſeed.

This genus of plants is ranged in the thirteenth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Gynandria. This ſection and claſs include thoſe plants which have the different ſexes on ſeparate plants, and the male flowers have their ſtamina adhering to the ſtyle.

The Species are,

1. Clutia (*Alaternoides*) foliis ſeſſilibus lineari-lanceolatis floribus ſolitariis erectis. Hort. Cliff. 500. *Clutia with linear ſpear-ſhaped leaves ſitting cloſe to the ſtalks, and ſolitary erect flowers.* Alaternoides Africana telephii legitimi imperati foliis. Hort. Amſt. 2.
2. Clutia (*Pulchella*) foliis ovatis integerrimis, floribus lateralibus. Lin. Sp. Plant. 1042. *Clutia with oval entire leaves, and flowers growing from the ſides of the branches.* Frutex Æthiopicus, portulace folio, flore ex albo vireſcente. Hort. Amſt. 1. p. 177.
3. Clutia (*Eleutheria*) foliis cordato lanceolatis. Flor. Zeyl. *Clutia with heart ſpear-ſhaped leaves.* Ricinus dulcis arboreſcens Americanus, populneâ fronde argenteâ. Pluk. Alm. 321.

The two firſt ſorts are natives of Africa, from whence they were brought to ſome curious gardens in Holland, and have ſince been communicated to moſt of the botanic gardens in Europe. The firſt ſort with male flowers has been long an inhabitant of ſome curious gardens in England; the other with female flowers has been lately introduced.

The ſecond ſort has alſo been ſome years in the Engliſh gardens, where we had not that ſort with male flowers till lately, when I was favoured with one by my learned friend Dr. Job Baſter, of Zirkzee in Holland.

The firſt ſort riſes with a ſhrubby ſtalk to the height of ſix or eight feet, putting out many ſide branches which grow erect; theſe are garniſhed with ſmall, linear, ſpear-ſhaped leaves, placed alternate, ſitting cloſe to the branches: they are of a grayiſh colour and entire. The flowers come out from the joints, at the ſetting on of the leaves: toward the upper part of the branches theſe are ſmall and of a greeniſh white; they appear in June, July, and Auguſt, but being ſmall make no great appearance.

The ſecond ſort riſes about the ſame height with the firſt, but hath a ſtronger ſtem; the branches are garniſhed with oval leaves, which are much larger than thoſe of the firſt ſort, ſtanding upon foot-ſtalks which are an inch long; they are of a ſea green, and entire; the flowers are like thoſe of the firſt ſort in ſhape and colour, but thoſe on the male plants are ſmaller, and grow cloſer together than thoſe of the female, but both are ſuſtained upon ſhort foot-ſtalks. Theſe flowers appear at the ſame time as thoſe of the firſt ſort, and the ſeeds ripen in autumn. I have raiſed ſeveral of theſe plants from ſeeds, which have all proved female, the ſame as the parent plant.

Theſe plants are eaſily propagated by cuttings during any of the ſummer months: if the cuttings are planted in ſmall pots, and plunged into a very moderate hot-bed, and ſhaded from the heat of the ſun in the middle of the day, they will ſoon take root, and ſhould then be inured to the open air, otherwiſe they will draw up very weak: afterward theſe plants may be each put into a ſeparate ſmall pot, and placed in a ſheltered ſituation, where they may remain until the middle of October, or later, if the weather continues mild, when they ſhould be removed into the green-houſe, and placed where they may have the free air in mild weather, for they only require to be protected from froſt, therefore require no warmth in winter; but if the green-houſe is ſhut up too cloſe, or the plants are much ſhaded by others, the tender ſhoots are ſubject to grow mouldy, which deſtroys more of theſe plants than the cold. In ſummer they muſt be placed abroad in a ſheltered ſituation, with other hardy exotic plants.

As theſe plants are always green, they look well in the green-houſe during the winter ſeaſon; and in ſummer, when they are placed in the open air with other exotic plants, they make a pretty variety.

The third ſort grows naturally in India, from whence the ſeeds were brought. This riſes with an upright ſhrubby ſtalk, not more than three or four feet high in England; but in the places where it grows naturally, it riſes upward of twenty feet high, and ſends out many branches at the top, ſo as to form a large ſpreading head: the branches are garniſhed with leaves, ſhaped like thoſe of the black Poplar, which are of a lucid green, and are placed alternate ſtanding upon ſlender foot-ſtalks. As theſe plants have not yet flowered in England, I can give no account of them, but the ſeed-veſſels are very like thoſe of the ſecond ſort.

This plant will live through the winter in an airy glaſs-caſe, without artificial heat; but in that ſituation they ſhould have very little water, for the plants abound with a milky juice like the Euphorbia, ſo muſt at no ſeaſon of the year have too much wet. If theſe plants, when young, are placed in a very moderate warmth in winter, it will greatly forward their growth, but they muſt not have too much heat, for that will force them too much; and when the plants have obtained ſtrength, they may be treated more hardily. This ſort may be propagated by cuttings during the ſummer ſeaſon; but the cuttings ſhould be laid in a dry place for a few days, when they are taken from the old plants, that their wounded parts may dry and be healed over before they are planted. Theſe muſt be planted in ſmall pots filled with light ſandy earth, and plunged into a moderate hot-bed of tanners bark; and if the ſeaſon is very warm, the glaſſes ſhould be ſhaded in the heat of the day, and raiſed up to admit freſh air to the cuttings every day; theſe muſt be ſparingly watered. When they have taken root, and begin to ſhoot, they muſt have a greater ſhare of air, and by degrees be inured to the open air; and when their roots have filled the pots, they ſhould be carefully parted, and each planted in a ſeparate pot of the ſame light ſandy earth; then they ſhould be placed on the back part of the ſtove, behind the other plants, where they may be ſcreened from the ſun till they have taken freſh root, after which they may be brought forward, and expoſed gradually to the open air. In the ſummer they ſhould have free air conſtantly in warm weather, but they muſt be ſcreened from heavy rain; and in winter placed in an airy glaſs-caſe, where they may enjoy the ſun, and during that ſeaſon have very little wet.

CLYPEOLA. Lin. Gen. Plant. 723. Jonthlaſpi. Tourn. Inſt. R. H. tab. 99. Treacle Muſtard.

The CHARACTERS are,

The flower hath a permanent empalement, compoſed of four oblong oval leaves. It hath four oblong entire petals, placed in form of a croſs, and ſix ſtamina which are ſhorter than the petals, two of which ſtanding oppoſite are ſhorter than the other, terminated by ſingle ſummits. In the center is ſituated a roundiſh compreſſed germen, ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes an orbicular pod, which is compreſſed, erect, and indented at the top, with a longitudinal fiſſure, opening in two cells, containing round compreſſed ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifteenth claſs, intitled Tetradynamia ſiliculoſa, the flower having four long and two ſhorter ſtamina, and the ſeeds growing in ſhort pods.

The SPECIES are,

1. CLYPEOLA (*Jonthlaſpi*) ſiliculis unilocularibus monoſpermis. Hort. Cliff. 329. *Clypeola with pods, having but one cell and a ſingle ſeed.* Jonthlaſpi minimum ſpicatum lunatum. Col. Ecp. 1. *Leaſt Buckler Muſtard with ſpiked flowers.*
2. CLYPEOLA (*Maritima*) ſiliculis bilocularibus ovatis diſpermis. Sauv. Monſp. 71. *Clypeola with oval pods having two cells and two ſeeds.* Thlaſpi Alyſſon dictum maritimum. C. B. P. 107.

This genus of plants was named Jonthlaſpi by Fabius Columna, and the ſame title was continued by Dr. Tournefort, and other late writers on botany before Dr. Linnæus, who has altered the name to this of Clypeola.

The firſt ſort is a low annual plant, which ſeldom riſes more than four inches high; the ſlender branches commonly lie proſtrate on the ground; theſe are garniſhed with ſmall leaves, narrow at their baſe, but are broader at their ends, where they are obtuſe. The flowers are produced in ſhort cloſe ſpikes at the extremity of the branches, which are ſmall, yellow, and compoſed of four petals, placed in form of a croſs; theſe are ſucceeded by orbicular compreſſed ſeed-veſſels, each having one cell, containing a ſingle ſeed. It flowers in June and July, and the ſeeds ripen in autumn.

The ſecond ſort is perennial. This ſends out from the root ſeveral ſlender branches, which divide again into many ſmaller, that lie proſtrate, garniſhed with very narrow hoary leaves, ſitting cloſe to the branches. The flowers are produced in ſpikes at the end of the branches; theſe are ſmall, yellow, and ſhaped like thoſe of the other ſort, but the ſpikes terminate in a roundiſh bunch. It flowers in June, and the ſeeds ripen in autumn.

Theſe two ſorts are low plants, which grow naturally in the ſouth of France, Spain, and Italy, and are preſerved in botanic gardens for the ſake of variety, but have little beauty; their leaves and ſtalks are of a hoary white, which is much lighter in the warm countries than in England; theſe are propagated by ſeeds, which ſhould be ſown upon a border of light earth where they are to remain, and will require no other culture, but to thin them if they come up too cloſe, and keep them clean from weeds. The ſeeds may be ſown either in the ſpring or autumn; thoſe which are ſown in autumn will grow much larger, and flower earlier than thoſe which are ſown in the ſpring, and from them there will be a greater certainty of having ripe ſeeds. If the ſeeds ſcatter, the plants will come up, and, if kept clean from weeds, they will thrive without farther care.

The ſecond ſort is a perennial plant, ſo ſhould be ſown upon a warm border and on a dry ſoil. This grows naturally on the borders of the ſea, in the ſouth of France and Italy; but when it is cultivated in a garden, if the ſoil is rich and moiſt, the plants generally grow luxuriant in ſummer, and are thereby too replete with moiſture, ſo that they are frequently killed by the froſt in winter; but when they grow on a poor, dry, gravelly ſoil, their ſtalks will be ſhort, ligneous, and tough, ſo will endure the cold of this climate, and continue ſeveral years. This is propagated by ſeeds, which ſhould be ſown where the plants are deſigned to remain; or if any of them are removed, it ſhould be done when the plants are young, for they do not bear tranſplanting well, when they are grown pretty large.

CNEORUM. Lin. Gen. Plant. 47. Chamelæa. Tourn. Inſt. R. H. 651. tab. 421. Widow-wail.

The Characters are,

The flower hath a ſmall permanent empalement, indented in three parts. It hath three narrow oblong petals, which are erect, and three ſtamina which are ſhorter than the petals, terminated by ſmall ſummits. In the center is ſituated an obtuſe three-cornered germen, ſupporting a firm erect ſtyle, crowned by a trifid ſpreading ſtigma. The germen afterward becomes a globular dry berry, with three lobes, having three cells, each containing one round ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, the flower having three ſtamina and one ſtyle.

We have but one Species of this genus, viz.

Cneorum (*Tricoccum*). Hort. Cliff. 18. Widow-wail. Chamelæa Tricoccos of Dodonæus and Caſpar Bauhin.

This is an humble ſhrub, which ſeldom riſes more than two feet and a half high in this country, but ſpreads out on every ſide with many lateral branches, ſo as to form a thick buſh. The ſtems are ligneous, and almoſt as hard as thoſe of the Box-tree, and the wood is of a pale yellow colour under the bark: the branches are garniſhed with thick ſtiff leaves, of an oblong oval ſhape, about an inch and a half long, and a quarter of an inch broad, of a dark green colour, having a ſtrong vein or rib through the middle. The flowers are produced ſingle from the wings of the leaves, toward the extremity of the branches, which are of a pale yellow colour, compoſed of three petals, which ſpread open, and a round germen at the bottom, having a ſingle ſtyle, which doth not riſe above half the length of the ſtamina, which are three in number, ſtanding erect, and are ſituated between the petals. After the flowers are fallen, the germen becomes a fruit, compoſed of three ſeeds joined together after the ſame manner as thoſe of Tithymalus or Spurge; theſe are firſt green, afterwards turn of a brown colour, and when ripe are black. The flowers begin to appear in May, and are ſucceeded by others during the ſummer months; and, when the autumn proves favourable, theſe ſhrubs will continue in flower till the end of October.

As this is a low evergreen ſhrub, it may be very ornamental, if placed in the front of plantations of evergreen trees and ſhrubs; for as the branches grow pretty compact, and are well garniſhed with leaves, it will hide the ground between the taller ſhrubs better than moſt other plants; and, being a durable ſhrub, will not want to be removed: it riſes better from ſcattered ſeeds, than if ſown with care.

This was formerly preſerved in green-houſes, and thought too tender to live in the open air in England; but of late years people have planted it in the full ground, where it reſiſts the cold of our ordinary winters very well, and is ſeldom injured but by extreme hard froſts; nor do theſe kill the plants which grow upon dry, rocky, or rubbiſhing ſoils, where their ſhoots are generally ſhort and firm; but in moiſt rich ground, where the ſhoots are more luxuriant, they are ſometimes injured.

It is propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe, and then the plants will come up the following ſpring; whereas thoſe which are not ſown till the ſpring, will remain a year in the ground, and often miſcarry: theſe ſeeds may be ſown in a bed of common earth, covering them half an inch deep, and will require no other care but to keep the plants clear from weeds the following ſummer; and in the autumn following, the plants may be tranſplanted where they are to remain.

CNICUS. Lin. Gen. Plant. 833. Tourn. Inſt. R. H. 450. tab. 257. Bleſſed Thiſtle.

The Characters are,

The empalement of the flower is compoſed of many oval ſcales, placed over each other; thoſe toward the top are terminated by branching ſpines. The flower is compoſed of ſeveral hermaphrodite florets, which are uniform; theſe are funnel-ſhaped, and cut at the top into five equal ſegments, ſtanding erect, each having five ſhort hairy ſtamina, terminated by cylindrical ſummits. In the center is ſituated a ſhort germen, crowned with down, ſupporting a ſlender ſtyle, terminated by an oblong ſtigma. The germen afterward becomes a ſingle ſeed, crowned with down, and ſhut up in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia Æqualis. The plants of this ſection have only hermaphrodite flowers, which are fruitful.

The Species are,

1. Cnicus (*Eriſithales*) caule erecto, foliis inferioribus laciniatis, ſuperioribus integris concavis. Hort. Cliff. 394. *Cnicus with an upright ſtalk, whoſe lower leaves are laciniated, the upper entire and concave.* Cnicus pratenſis, Acanthi folio, flore flaveſcente. Tourn. Inſt. 450.
2. Cnicus (*Spinoſiſſimus*) foliis amplexicaulibus, ſinuato-pinnatis, ſpinoſis, caule ſimplici, floribus ſeſſilibus. Lin. Sp. Plant. 826. *Cnicus with winged, ſinuated, prickly leaves embracing the ſtalk, and flowers ſitting cloſe on the top.* Cirſium Alpinum ſpinoſiſſimum, floribus ochro-leucis inter flaveſcentia folia congeſtis. Haller. tab. 20.
3. Cnicus (*Cernuus*) foliis cordatis, petiolis criſpis ſpinoſis amplexicaulibus, floribus cernuis. Hort. Upſal. 251. *Cnicus with heart-ſhaped leaves, having curled prickly foot-ſtalks which embrace the ſtalks, and a nodding flower.* Carduus foliis ex cordato-lanceolatis, margine ſerratis & ſpinoſis, ſquamis calycum membranaceis, laceris ſpinoſis, capitulis nutantibus. Flor. Sib. 2. p. 47.

The firſt ſort grows naturally in the northern parts of Europe. Mr. Ray found it growing on the Rhine near Baſil. This hath a perennial root, which ſends out many long jagged leaves, ſpreading on every ſide near the ground, ſo as to form a thick tuft; theſe are jagged almoſt to the midrib, in form of a winged leaf. The ſtalks are ſtriated, ſmooth, and riſe above four feet high, dividing at the top into ſmaller branches: the leaves which grow upon the ſtalks are entire, heart-ſhaped, concave, and embrace the ſtalks, and are ſawed on their edges, each indenture ending in a weak ſpine: the ſtalks are terminated by large heads of flowers, growing in cluſters; they are of a whitiſh yellow colour, and incloſed in a ſcaly empalement, and are ſucceeded by ſmall oblong ſeeds, crowned with a briſtly down. It flowers in June, and the ſeeds ripen in autumn.

This ſort may be propagated by ſeeds, or parting the roots; the latter is commonly practiſed where there are any of the plants, but the ſeeds are more eaſily conveyed to a diſtant place. The beſt time to part the roots is in autumn; it delights in ſhade, and requires no farther care but to keep it clean from weeds.

The ſecond ſort grows naturally on the Alps, and on the mountains of Auſtria. This riſes with an upright ſingle ſtalk near four feet high, garniſhed with ſinuated leaves, which are very prickly, and embrace the ſtalks with their baſe. The flowers are produced at the top of the ſtalk, ſurrounded by a cluſter of broad prickly leaves, ſitting cloſe to the ſtalk; they are of a whitiſh yellow, and appear at the ſame time with the former ſort. It is a perennial plant, which may be propagated in the ſame manner as the former, and requires a moiſt ſoil and a ſhady ſituation.

The third ſort grows naturally in Siberia, from whence the ſeeds were ſent to the imperial garden at Peterſburgh, where they ſucceeded, and produced ſeeds, part of which were ſent me by the profeſſor of botany; this hath a perennial root, compoſed of thick fleſhy fibres. The leaves which riſe immediately from the root are near a foot long, and near ſix inches broad in the middle, diminiſhing toward each end, and at a little diſtance from the baſe are much contracted, but are wider at the end; theſe have ſcarce any foot-ſtalks; they are of a deep green on their upper ſide, but white on their under, and ſharply ſawed on their edges. The ſtalks riſe more than ſix feet high, ſending out on each ſide ſmall branches above a foot long; the ſtalks are ſtriated, and of a reddiſh colour; they are garniſhed with heart-ſhaped leaves, which almoſt embrace the ſtalks with their baſe, and are of the ſame colour with thoſe below; each branch is terminated by one large globular head of yellowiſh flowers, included in a ſcaly empalement, each ſcale ending with a ſharp ſpine. This flowers in June, and the ſeeds ripen in autumn. It may be propagated in the ſame manner as the two former ſorts, but requires a moiſt ſoil and ſhady ſituation; and if the weeds are kept down, there will be no farther care required. The inhabitants of Siberia eat the tender ſtalks of this plant, when boiled, inſtead of other vegetables.

This is a perennial plant, which may be propagated by parting the roots: the beſt time for doing of this is in autumn, that the plants may get good root in winter; for thoſe which are tranſplanted in the ſpring, do not flower well the firſt year, unleſs they are planted in a moiſt ſoil. As theſe plants grow very large, they are not proper furniture for ſmall gardens, where they will take up too much room; for they ſhould not be planted nearer than four feet from each other, for if they are too near any other plants, they will rob them of their nouriſhment; for the roots of theſe extend to a great diſtance, ſo that two or three of theſe plants, for variety, are ſufficient for any garden, which may be planted at a diſtance from choicer plants.

It is alſo propagated by ſeeds, which may be ſown in the ſpring on a bed of common ground, in the ſame manner as the other ſorts; and will only require to be thinned, and kept clean from weeds till autumn, when they may be tranſplanted where they are deſigned to remain.

COCCIGRIA. See RHUS.

COCHLEARIA. Lin. Gen. Plant. 720. Tourn. Inſt. R. H. 215. tab. 101. [ſo called of Cochleare, *Lat.* a ſpoon, becauſe the leaves of this plant are hollowed like a ſpoon.] Spoonwort, or Scurvy Graſs.

The CHARACTERS are,

The empalement of the flower is compoſed of four oval concave leaves. The flower hath four petals, placed in form of a croſs, which ſpread open, and are twice as large as the leaves of the empalement; it hath ſix ſtamina, four of which are longer than the other two; theſe are terminated by obtuſe compreſſed ſummits. The germen is heart-ſhaped, ſupporting a ſhort ſingle ſtyle, crowned by an obtuſe ſtigma: this afterward becomes a gibbous, heart-ſhaped, compreſſed pod, faſtened to the ſtyle, having two cells, in each of which are lodged four roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliculoſa. The flowers of this claſs have four long and two ſhort ſtamina, and thoſe of this ſection have very ſhort pods.

The SPECIES are,

1. COCHLEARIA (*Officinalis*) foliis radicalibus ſubrotundis, caulinis oblongis ſubſinuatis. Flor. Lapp. 256. *Scurvy Graſs whoſe lower leaves are roundiſh, and thoſe on the ſtalks oblong and ſinuated.* Cochlearia folio ſubrotundo. C. B. P. 110. *Round-leaved Scurvy Graſs.*
2. COCHLEARIA (*Anglica*) foliis ovato-lanceolatis, ſinuatis. Flor. Ang. 248. *Scurvy Graſs with oval ſpear-ſhaped leaves, which are ſinuated.* Cochlearia folio ſinuato. C. B. P. 110. *Sea Scurvy Graſs.*
3. COCHLEARIA (*Grænlandica*) foliis reniformibus, carnoſis integerrimis. Hort. Cliff. 498. *Scurvy Graſs with kidney-ſhaped leaves, which are fleſhy and entire.* Cochlearia minima ex montibus Walliæ. Sher. Boerh. Ind. alt. 2. p. 10.
4. COCHLEARIA (*Danica*) foliis haſtatis, angulatis. Flor. Suec. 196. *Scurvy Graſs with angular ſpear-ſhaped leaves.* Cochlearia Armorica. H. R. Par. *Daniſh, or Ivy-leaved Scurvy Graſs.*
5. COCHLERIA (*Armoracia*) foliis radicalibus lanceolatis, crenatis, caulinis inciſis. Hort. Cliff. 332. *Scurvy Graſs whoſe lower leaves are ſpear-ſhaped and crenated, and thoſe on the ſtalks jagged.* Raphanus Ruſticanus. C. B. P. 96. *Horſe Radiſh.*
6. COCHLEARIA (*Glaſtifolia*) foliis caulinis cordato-ſagittatis, amplexicaulibus. Hort. Cliff. 332. *Scurvy Graſs whoſe upper leaves are arrow-pointed, heart-ſhaped, and embrace the ſtalks.* Cochlearia altiſſima glaſti folio. Inſt. R. H. 216.

The firſt ſort grows naturally on the ſea-ſhore in the north of England, and in Holland, but is cultivated for uſe in the gardens near London. This is an annual plant, for the ſeeds are ſown, and the plants decay within the compaſs of one year, but the ſeeds ſhould be ſown early in autumn; this hath a fibrous root, from which ariſe many round ſucculent leaves, which are hollowed like a ſpoon; the ſtalks riſe from ſix inches to a foot high; theſe are brittle, and garniſhed with leaves, which are oblong and ſinuated. The flowers are produced in cluſters at the end of the branches, conſiſting of four ſmall white petals, which are placed in form of a croſs, and are ſucceeded by ſhort, roundiſh, ſwelling ſeed-veſſels, having two cells, divided by a thin partition; in each of theſe is lodged four or five roundiſh ſeeds. It flowers in April, and the ſeeds ripen in June, ſoon after which it decays.

This ſort is propagated in gardens for medicinal uſes, which is done by ſowing the ſeeds in July, ſoon after they are ripe, in a moiſt ſhady ſpot of ground; and when the plants are come up, they ſhould be thinned, ſo as to be left at about four inches diſtance each way. The plants that are taken out may be tranſplanted into other ſhady borders, if there is occaſion for them, otherwiſe they may be hoed out (as is practiſed for Onions, Carrots, &c.) and at the ſame time all the weeds may be hoed down, ſo as to clear the plants entirely from them, that they may have room to grow ſtrong. In the ſpring theſe plants will be fit for uſe; and thoſe that are ſuffered to remain will run up to ſeed in May, and perfect their ſeeds in June. If this plant is ſown in the ſpring, the ſeeds ſeldom grow well, therefore the beſt time is ſoon after they are ripe. The plants rarely live after producing ſeeds, ſo that it ſhould be ſown every year, to have it for uſe.

The Sea Scurvy Graſs is alſo uſed in medicine; but this grows in the ſalt marſhes in Kent and Eſſex, where the ſalt water overflows it almoſt every tide, and can rarely be made to grow in a garden, or at leaſt to laſt longer there than one year; but it being eaſily gathered in the places before-mentioned, the markets are ſupplied from thence by the herb-women, who make it their buſineſs to gather herbs.

This ſort differs from the firſt in the ſhape of its leaves, theſe being longer, and ſinuated on their edges. It flowers a little later in the ſeaſon; both theſe ſorts are uſed in medicine.

The little Welch Scurvy Graſs is a biennial plant, and may be preſerved in a garden, if planted in a ſtrong ſoil and a ſhady ſituation. This is preſerved in curious gardens of plants, but is not of any uſe in medicine, though it is by far the warmeſt and moſt pungent of all the ſorts. This grows plentifully in Muſcovy, as alſo in Davis's Streights.

The fourth ſort is a low trailing plant, whoſe ſtalks grow ſix inches long, and lie proſtrate on the ground; the leaves are angular, and in ſhape like thoſe of Ivy. This is found growing naturally in ſome parts of England, and is annual. It flowers and ſeeds about the ſame time as the firſt ſort.

The ſixth ſort is a biennial plant, which uſually grows about a foot and a half high, with upright ſtalks, garniſhed with angular heart-ſhaped leaves, embracing the ſtalks with their baſe; the flowers are produced in looſe ſpikes at the end of the branches; they are very ſmall, white, and are ſucceeded by ſhort ſwelling pods filled with round ſeeds. It flowers in May, and the ſeeds ripen in July and Auguſt. This may be propagated by ſeeds as the common ſort; and if ſown in autumn, will more certainly ſucceed than in the ſpring.

The Horſe Radiſh is propagated by cuttings or buds from the ſides of the old roots. The beſt ſeaſon for this work is in October or February; the former for dry lands, the latter for moiſt; the ground ſhould be trenched at leaſt two ſpits deep, or more if it will allow of it. The manner of planting it is as follows: provide yourſelf with a good quantity of offſets, which ſhould have a bud upon their crowns, but it matters not how ſhort they are; therefore the upper part of the roots which are taken up for uſe, may be cut off about two inches long with the bud to it, which is eſteemed the beſt for planting. Then make a trench ten inches deep, in which you ſhould place the offſets at about four or five inches diſtance each way, with the bud upward, covering them up with the mould that was taken out of the trench: then proceed to a ſecond trench in like manner, and continue the ſame till the whole ſpot of ground is planted. After this, level the ſurface of the ground even, obſerving to keep it clear from weeds, until the plants are ſo far advanced, as to be ſtrong enough to overbear and keep them down. With this management the roots of the Horſe Radiſh will be long and ſtrait, and free from ſmall lateral roots, and the ſecond year after planting will be fit for uſe. 'Tis true, they may be taken up the firſt year, but then the roots will be but ſlender; therefore it is the better way to let them remain until the ſecond year. The ground in which this is planted ought to be very rich, otherwiſe the roots will make but a ſmall progreſs.

COCOS. Lin. Gen. Plant. 1223. The Cocoa Nut.

The Characters are,

There are male and female flowers on the ſame tree. The univerſal ſpatha has one valve. The empalement conſiſts of three ſmall-coloured concave leaves; the flower has three oval ſpreading petals, and ſix ſtamina the length of the corolla, terminated by triangular ſummits. The germen is ſcarce diſcernible, ſupporting three ſhort ſtyles, crowned by obſolete ſtigma; theſe are barren. The female flowers are included in the like ſpatha. The empalement is three-leaved, which is coloured and permanent; they have three petals to the flowers, which are larger than the empalement, and an oval germen without a ſtyle, with a three-lobed ſtigma. The nut is large, triangular, and is perforated by three holes at the end.

This genus is placed by Linnæus in his appendix under the title of Monoica Hexandria, the ſame plants having hermaphrodite and female flowers, the hermaphrodite having ſix ſtamina.

We know but one Species of this genus, viz.

Cocos (*Nucifera*) frondibus pinnatis, foliolis enſiformibus replicatis. Jacq. Hiſt. 168. *Cocoa Nut with winged branches, whoſe ſmall leaves are ſword-ſhaped and folded.* Palma Indica coccifera anguloſa. C. B. P. 502.

This tree is cultivated in both Indies, but is generally ſuppoſed to grow naturally in the Maldives, and other deſart iſlands of the Eaſt-Indies. The trees grow to a great height in their native places, but their ſtems are compoſed of ſtrong fibres like net-work, which lie in ſeveral lamina over each other, out of which come the branches (or rather leaves,) which grow twelve or fourteen feet long. The midrib is garniſhed with ſword-ſhaped ſmall leaves, whoſe borders fold backward: the firſt leaves which puſh out from the nut when planted, are very different from thoſe which are afterward produced; for they are very broad, and have many folds in each: whereas, the after leaves have a ſtrong midrib, of great length, on which the ſmaller lobes are placed alternately; theſe lobes are from ſix to eight or nine inches long, and are almoſt triangular, having very ſharp points, and are very ſtiff. The flowers come out round the top of the trunk of the tree in large cluſters; they are incloſed in a large ſpatha or ſheath, and the nuts afterward are formed in large cluſters; theſe are included in large net-work covers, which adhere cloſely about them; the nut has a hard ſhell, with three holes at the upper end. The kernel is large, ſweet, and the lower part of the ſhell, when firſt taken from the tree, is filled with a pale liquor, which the inhabitants of the countries where the trees grow, call milk, and they are very fond of it. From this milk I have been informed by perſons of credit, there has been exceeding good arrack diſtilled in Jamaica.

The plants are propagated by planting the nuts in ſuch places where they are deſigned to remain; for the plants will not bear tranſplanting, unleſs it is performed while they are very young, for their roots ſhoot deep and wide; ſo that if theſe are cut or broken, the plants ſeldom ſurvive it, which is generally the caſe with moſt of the kind of Palms.

Where any perſons are deſirous of having a plant or two of this ſort, they ſhould procure ſome freſh nuts from the neareſt place of their growth, which, on their arrival in England, ſhould be buried in a warm bed of tanners bark, laying them on one ſide, that the young ſhoot which comes out from one of the three holes may not be injured by wet, covering them about ſix inches deep with the tan. In this ſituation, if the nuts are good, they will put out ſhoots in ſix weeks or two months, ſo ſhould be then carefully taken up, and each planted in a ſeparate pot filled with kitchen-garden earth, and plunged into the tan-bed in the ſtove, where the plants ſhould always remain, for they are too tender to thrive in any other ſituation; but as the plants advance in their growth, they ſhould be ſhifted into larger pots or tubs, being careful not to cut or tear their roots in the operation.

This is one of the moſt uſeful trees to the inhabitants of America, who make many neceſſary utenſils from the ſeveral parts of it. The outer cover of the nuts is made into cordage; the ſhells are converted into drinking bowls; the kernel of the nuts affords them a wholeſome food, and the milk a cooling liquor. The leaves of the tree are uſed for thatching of their houſes, and are alſo wrought into baſkets, and many other things which are made of Oſiers in Europe.

COCCOLOBA, Sea-ſide Grape.

The Characters are,

The empalement is of one leaf, cut into five parts, which ſpread open and are permanent. The flower has no corolla, but hath eight awl-ſhaped ſpreading ſtamina, terminated by roundiſh twin ſummits. It has an oval three-cornered germen, ſupporting three ſhort ſpreading ſtyles, crowned by ſimple ſtigmas. The empalement afterward becomes a thick berry, incloſing an oval-

pointed nut, with one cell, having a ſingle ſeed of the ſame form.

This genus of plants is ranged in the third ſection of Linnæus's eighth genera, intitled Octandria Trigynia, the flowers having eight ſtamina and three ſtyles.

The Species are,

1. Coccoloba (*Uvifera*) foliis cordato-ſubrotundis nitidis. Lin. Sp. 523. *Sea-ſide Grape with neat, roundiſh, heart-ſhaped leaves.* Guajabara racemoſa, foliis coriaceis ſubrotundis. Plum. Nov. Gen.
2. Coccoloba (*Rubeſcens*) foliis orbiculatis pubeſcentibus. Lin. Sp. 523. *Sea-ſide Grape with orbicular hairy leaves.* Scortea arbor Americana, ampliſſimis foliis averſa parte nervis extantibus. Pluk. Phyt. 222. f. 8.
3. Coccoloba (*Punctata*) foliis lanceolato-ovatis. Lin. Sp. 523. *Sea-ſide Grape with oval ſpear-ſhaped leaves.* Uvifera arbor Americana, fructu aromatico punctato. Pluk. Alm. 394.
4. Coccoloba (*Excoriato*) foliis ovatis, ramis quaſi excorticatis. Lin. Sp. 524. *Sea-ſide Grape with oval leaves, and the branches caſting their bark.* Guajabara alia racemoſa, foliis oblongis. Plum. Icon. 146. f. 1. *Called Mountain Grape.*
5. Coccoloba (*Tenuifolia*) foliis ovatis membranaceis. Amœn. Acad. 5. p. 397. *Sea-ſide Grape with oval membranaceous leaves.*

The firſt ſort riſes with many ligneous ſtems to the height of ten or twelve feet, having ſeveral knots or joints, covered with a gray bark: at each joint is ſet on one large, roundiſh, ſmooth leaf, a little indented at the top. The flowers come out from the foot-ſtalks of the leaves, in long bunches like thoſe of Currants; they have no petals, but the empalement is cut into five ſegments, including eight awl-ſhaped ſtamina, terminated by twin ſummits. The germen afterward becomes a ſucculent berry, including an oval-pointed nut, having one ſeed of the ſame form.

The ſecond ſort ſeldom riſes ſo high as the firſt, but divides into ſeveral lateral branches, garniſhed with large roundiſh leaves, having ſeveral deep veins; the flowers and fruit come out from the ſide of the branches in like manner as thoſe of the firſt, but are larger.

The third ſort is a lower ſhrub than either of the former; the leaves are oval and ſpear-ſhaped; the fruit is ſmaller, ſomewhat aromatic, and ſpotted; theſe proceed from the ſide of the branches in like manner as the former ſorts.

The fourth ſort grows to a much larger ſize than any of the other; the leaves of this are much larger, of an oblong oval form, very ſmooth, and of a lucid green: from the wings of the leaves, the flowers and fruit are produced, which are in form like thoſe of the other ſorts, but are larger.

The fifth ſort is of humbler growth than either of the former; the leaves are membranaceous, of an oval form; the flowers and fruit are ſmaller than thoſe of the other ſorts. Theſe plants all grow naturally in the warm iſlands of America; ſome of them on the ſea-ſhores, where they form very cloſe, almoſt impenetrable thickets; the fruit of the firſt ſort are frequently eaten by the inhabitants of the iſlands, but eſpecially by the negroes. Thoſe of the other ſorts are food for birds.

The plants of all the ſorts are eaſily propagated by ſeeds, when they can be obtained freſh from the places of their natural growth (for none of the ſorts have as yet produced either fruit or flowers in England.) The ſeeds ſhould be ſown in ſmall pots filled with earth from the kitchen-garden, and plunged into a hot-bed. If the ſeeds are good, and the bed of a proper temperature of warmth, the plants will appear in five or ſix weeks after, which will be fit to tranſplant in about a month after; when they ſhould be ſhaken out of the pots, ſeparating their roots carefully, and each planted in a ſeparate ſmall pot filled with the like earth, plunging them into a hot-bed of tanners bark, being careful to ſhade them in the day-time, until they have taken new root; after which they ſhould be treated in the ſame way as other tender exotic plants, which require to be kept conſtantly in the bark-ſtove.

CODLIN-TREE. See Malus.

COFFEA. Lin. Gen. Plant. 209. Juſſ. Act. Reg. Scien. 1713. Jaſminum. Com. Cat. The Coffee-tree.

The Characters are,

The flower hath a ſmall empalement divided into four parts, ſitting upon the germen. It hath one petal which is funnel-ſhaped, having a narrow cylindrical tube, which is much longer than the empalement, but is plain at the top, where it is indented in five parts. It hath five ſtamina which are faſtened to the tube, and are terminated by long ſlender ſummits. The roundiſh germen ſupports a ſingle ſtyle, crowned by two thick reflexed ſtigmas. The germen afterward becomes an oval berry, containing two hemiſpherical ſeeds, plain on one ſide, and convex on the other.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle; it hath been generally included in the genus of Jaſmines; but as the flowers of Jaſmine have but two ſtamina, ſo by Linnæus's ſyſtem, this is ſeparated and ranged in another claſs.

We have but one Species of this genus, viz.

Coffea (*Arabica.*) Hort. Cliff. 59. The Coffee-tree. Jaſminum Arabicum Caſtaneæ folio, flore albo odoratiſſimo, cujus fructus Coffea in officinis dicuntur nobis. Juſſ. Act. Par. 1713.

This tree is ſuppoſed to be a native of Arabia Felix, where it was firſt cultivated for uſe, and to this day, is the country from whence the beſt Coffee is brought to Europe, though the plant is now propagated in many parts of India and America; but the produce of thoſe countries being greatly inferior to that of Arabia, hath occaſioned its preſent diſrepute in England, ſo that it is ſcarce worth importing; but this might be remedied, if the Coffee planters in the Weſt Indies could be prevailed on to try a few experiments, which I ſhall hereafter propoſe, being founded on thoſe which have been made in England, upon the berries produced here. But I ſhall firſt treat of the plant, with its culture in England.

This is a low tree in the native country of its growth, where it ſeldom riſes more than ſixteen or eighteen feet high, but in England I have not ſeen any above ten or twelve. The main ſtem grows upright, and is covered with a light brown bark; the branches are produced horizontally and oppoſite, which croſs each other at every joint, ſo that every ſide of the tree is fully garniſhed with them: the lower branches being the longeſt, the others gradually decreaſing to the top, form a ſort of pyramid; the leaves are alſo produced oppoſite; theſe when fully grown, are about four or five inches long, and one inch and a half broad in the middle, decreaſing toward each end; the borders are waved, and the ſurface is of a lucid green. The flowers are produced in cluſters at the baſe of the leaves, ſitting cloſe to the branches; theſe are tubulous, ſpread open at the top, where they are divided into five parts, and are of a pure white, with a very grateful odour, but of ſhort duration: they are ſucceeded by oval berries, which are firſt green, when fully grown, they turn red, and afterward change to black when fully ripe; theſe have a thin pulpy ſkin, under which are two ſeeds joined, which are flat on the joined ſides, with a longitudinal furrow, and convex on their outer ſide.

As the Coffee-tree is an Evergreen, it makes a beautiful appearance at every ſeaſon in the ſtove, but particularly when it is in flower; and alſo when the berries are red, which is generally in the winter; ſo that they continue a long time in that ſtate, therefore there is ſcarce any plant that more deſerves a place in the ſtove than this.

It is propagated by the berries, which muſt be ſown ſoon after they are gathered from the trees, for if they are kept out of the ground a ſhort time they will not grow. I have frequently ſent the berries abroad by the poſt, but when they have been a fortnight in their journey they have all failed; and this has conſtantly happened every where, for the berries which were ſent from Holland to Paris did not grow, nor did thoſe which were ſent from Paris to England grow; ſo that wherever theſe trees are deſired, the young plants muſt be ſent, if it be at any diſtance from the place where they grow.

The berries ſhould be planted in ſmall pots, filled with light kitchen-garden earth, and plunged into a hot-bed of tanners-bark; the pots muſt be watered gently once or twice a week, but the earth muſt not be too moiſt, leſt it rot the berries. If the bed be of a proper temperature of warmth, the plants will appear in a month or five weeks time, and in about two months more will be fit to tranſplant. For as many of the berries will produce two plants, ſo the ſooner they are parted, the better their roots will be formed; for when they grow double till they have made large roots, they will be ſo intermixed and entangled, as to render it difficult to ſeparate them without tearing off their fibres, which will greatly prejudice the plants. When theſe are tranſplanted, they muſt be each put into a ſeparate ſmall pot, filled with the ſame earth as before, and plunged into the tan-bed again; which ſhould be ſtirred up to the bottom, and if required, ſome new tan ſhould be mixed with it, to renew the heat. Then the plants ſhould be gently watered, and the glaſſes of the hot-bed muſt be ſhaded every day till they have taken new root; after which the plants ſhould have free air admitted to them every day, in proportion to the warmth of the ſeaſon: during the ſummer they will require frequently to be refreſhed with water, but they muſt not have it in too great plenty: for if their roots are kept too moiſt, they are very ſubject to rot, then the leaves will ſoon decay and drop off, and the plants become naked; when this happens, they are ſeldom recovered again. The firſt ſign of theſe plants being diſordered, is, their leaves ſweating out a clammy juice, which attracts the ſmall inſects, that too frequently infeſt the plants in ſtoves; when they are not in health, theſe inſects cannot be deſtroyed, till the plants are recovered to vigour: for although the plants are ever ſo carefully waſhed and cleaned from them, yet they will be ſoon attacked by them again, if they are not recovered to health, for theſe inſects are never ſeen upon any of the plants while they are in perfect vigour; but when they are diſordered, they ſoon ſpread over all the leaves and tender parts of the plants, and multiply exceedingly; ſo that upon the firſt attack, the plants ſhould be ſhifted into freſh earth, and all poſſible care taken to recover them, without which all the waſhing and cleaning of the plants will be to little purpoſe. The diſorders attending the Coffee-trees, generally proceed from either being put into pots too large for them, nothing being of worſe conſequence than over potting them; or from the earth being too ſtiff, or over-hung by other plants, or being over watered. If theſe are properly taken care of, and the ſtove kept always in a proper temperature of heat, the plants will thrive, and produce plenty of fruit.

I have made trial of ſeveral compoſitions of earth for theſe plants, but have found none of them equal to that of a kitchen-garden, where the ſoil is naturally looſe, and not ſubject to bind; and if it has conſtantly been well wrought and properly dunged, this without any mixture is preferable to any other.

The plants ſhould not be too often tranſplanted, for that will greatly retard their growth. If they are new potted twice a year at moſt, it will be ſufficient; though unleſs the plants make great progreſs, they will not require to be removed oftener than once in a year, which ſhould be in ſummer, that they may have time to get good roots again before winter. During the warm weather in ſummer, theſe plants ſhould have a large ſhare of air, but they muſt not be wholly expoſed abroad at any ſeaſon: for although they may have the appearance of thriving in the open air during the heat of ſummer, yet when they are removed into the ſtove again, their leaves will fall off, and the plants will make but an indifferent appearance the following winter, if they ſhould ſurvive it: therefore it is the better method to keep them conſtantly in the ſtove, and admit a proportionable ſhare of air to them every day, according to the heat of the ſeaſon; they will require water two or three times a week in warm weather, but in the winter they muſt have it more ſparingly; and the ſtove in which they are placed, ſhould be kept to the heat aſſigned for the Ananas upon the botanical thermometors.

There has been ſome of theſe plants propagated by cuttings, and alſo from layers; but theſe are long before they make roots, and the plants ſo raiſed, are never ſo ſtrong and thriving as thoſe which ariſe from berries; therefore where the berries can be procured, it is much the beſt method to propagate the plants by ſeeds.

When the plants are tranſplanted, their roots ſhould not be too much cut or trimmed; the decayed or rotten fibres ſhould be pruned off, and thoſe which are cloſely matted to the ſide of the pots ſhould be trimmed, but not cut too near to the ſtem; for the old fibres do not put out new roots very kindly, eſpecially thoſe which are become tough, ſo that there ſhould always be a ſufficient number of young fibres left to ſupport the plants, till new ones are produced.

The Coffee plants were firſt carried from Arabia to Batavia by the Dutch, and from thence they were afterward brought to Holland, where great numbers of the plants were raiſed from the berries which thoſe plants produced, and from theſe moſt of the gardens in Europe have been furniſhed. A great number of theſe young plants, which were raiſed at Amſterdam, were ſent to Surinam by the proprietors of that iſland, where the trees were ſoon propagated in great plenty, and from thence the plants have been diſperſed to moſt of the iſlands in the Weſt Indies: for as the plants raiſed from the berries, produce fruit in two years from planting, and in the warm countries ſooner, ſo plantations of theſe trees may be ſoon made in any of thoſe countries, where the temperature of the air is proper for their production, but the trees will not grow in the open air any where if there is a winter: ſo that in all countries without the tropics, they cannot be expected to grow abroad.

The French have made great plantations of theſe trees in their ſettlements in the Weſt Indies, and alſo in the iſle of Bourbon, from whence they import great quantities of Coffee annually to France; which although greatly inferior in quality to the Arabian, yet it is conſumed, otherwiſe they would not continue that branch of commerce. In the Britiſh colonies of America, there have been ſome large plantations made of Coffee-trees: and it was propoſed to the parliament, ſome years paſt, to give a proper encouragement for cultivating this commodity in America, ſo as to enable the planters to underſell the importers of Coffee from Arabia. Accordingly there was an abatement of the duty payable on all the Coffee which ſhould be of the growth of our colonies in America, which at that time was ſuppoſed would be a ſufficient encouragement for the planters to improve this branch of commerce: but the productions of thoſe countries, being greatly inferior in quality to that of Arabia, hath almoſt ruined the project; and unleſs the planters can be prevailed on to try ſome experiments to improve its quality, there can be little hope of its becoming a valuable branch of trade; therefore I ſhall beg leave to offer my ſentiments on this article, and ſincerely wiſh what I have to propoſe may be found uſeful for the inſtruction of the Coffee planters; for as my opinion is founded upon experiments, ſo it is not mere theory or ſuppoſition.

The great fault of the Coffee which grows in America, and alſo in the iſle of Bourbon, is the want of flavour, or having a diſagreeable one. The berries are much larger than thoſe which are imported from Arabia, and conſequently have not ſo much ſpirit or flavour. This may be owing to ſeveral cauſes, the firſt is that of its growing in a ſoil too moiſt; which is always known to increaſe the ſize of fruit and vegetables, but their quality is greatly diminiſhed thereby. The ſecond is from the gathering of the berries too ſoon; for I have been credibly informed, that it is the conſtant practice of the planters, to gather the fruit when it is red: at which time the berries are much larger, and of greater weight, than thoſe which are permitted to ripen perfectly on the trees, which is not till they are turned black, and their outer pulp becomes dry, and the ſkins ſhrink: then the berries are much ſmaller than before, and the outer cover will eaſily ſeparate from the berry; which I have always been informed, has been the complaint of the planters, that this was with great difficulty and trouble effected. A third cauſe I imgine may be in the drying of the berries when gathered; which muſt be conſtantly attended to, for they cannot be too much expoſed to the ſun and air in the day time, but they muſt be every evening removed under cover, and carefully ſcreened from dews and rain; nor ſhould they be placed near any ſort of liquid or moiſture, for theſe berries are very ſubject to imbibe moiſture, and thereby acquire the flavour of the liquid; or if it be pure water, the berries will be enlarged, and the flavour diminiſhed by it, as from many experiments I can affirm: for a bottle of rum being placed in a cloſet, in which a caniſter of Coffee berries cloſely ſtopped, was ſtanding on a ſhelf at a conſiderable diſtance, in a few days had ſo impregnated the berries, as to render them very diſagreeable; the ſame alſo has happened by a bottle of ſpirits of wine ſtanding in the ſame cloſet with Coffee and Tea, both which were in a few days ſpoiled by it. Therefore from many experiments of this nature, which I have made with Coffee, it appears to me that it ſhould never be brought over in ſhips freighted with rum, nor ſhould the berries be laid to dry in the houſes where the ſugars are boiled, or the rum diſtilled. I have alſo been informed by a gentleman who has a very good eſtate in Jamaica, and who has lived many years in that iſland, that the planters frequently boil the Coffee berries before they are dried. As this information comes from a gentleman of great ſkill and veracity, ſo I cannot doubt of the fact; and if ſo, this alone is ſufficient to ſpoil the beſt Coffee in the world; ſo that I am at a loſs to gueſs the reaſon for this practice, which, as it appears to me, can only be intended to increaſe the weight, therefore muſt be imputed to avarice, the bane of every public good.

There was ſome time paſt an imperfect account printed in the papers, of the cauſe why the American Coffee was not ſo good as that which comes from Arabia; in which it is ſuppoſed, that the goodneſs of the latter proceeded from the length of time which the berries had been kept: therefore the author propoſes that the American Coffee berries ſhould be many years kept, which he ſays will render them equally good. This is contrary to all the experience I have had, or can learn, from thoſe who have ſeen the whole progreſs of Coffee in Arabia, with their manner of drying and packing it to ſend abroad; for two gentlemen who had lived there ſome years aſſured me, that the berries, when firſt gathered, were much better than thoſe which are kept any time. And a curious gentleman who reſided in Barbadoes two years, alſo told me, that he never drank better Coffee in any part of the world, than what he made from the freſh berries which he gathered himſelf, and roaſted as he had occaſion for them; which is alſo confirmed by the trials which have been made with the berries which grow in the ſtoves in England, which make a better flavoured liquor, than the beſt Arabian Coffee berries which can be procured in England; therefore I wiſh thoſe who are inclinable to cultivate theſe trees in America, would make choice of a ſoil rather dry than moiſt, in which the trees will not make ſo great progreſs as thoſe which grow in a wet ſoil, nor will the produce be ſo great; but as the quality of the produce will be ſo much improved, it will certainly be of greater advantage to them.

The next thing is, to permit the berries to remain ſo long upon the trees, till their ſkins are ſhrivelled and turned very black; which it is true will greatly diminiſh their weight, but then the commodity will be more than double the value of that which is gathered ſooner.

When the berries are fully ripe, they ſhould be gathered, or rather ſhaken from the trees, when they are perfectly dry, and ſpread abroad upon cloths in the ſun to dry, carrying them every evening under cover, to prevent the dews from falling on them, or the rain if any ſhould happen: and when they are perfectly dry, they ſhould be carefully packed up in cloths or bags, three or four times double, and conſequently kept in a dry ſituation: and when they are ſhipped for England, it ſhould be on board thoſe veſſels which have no rum, leſt the Coffee ſhould imbibe the flavour, which cannot be prevented when ſtowed in the ſame place. For ſome years paſt, a Coffee ſhip from India had a few bags of pepper put on board, the flavour of which was imbibed by the Coffee, and the whole cargo ſpoiled thereby.

As the quantity of Coffee now conſumed in Britain is very much increaſed of late years, ſo it will certainly be worthy of public conſideration, how far it may be neceſſary to encourage the growth of it in the Britiſh colonies: and certainly it deſerves the attention of the inhabitants of thoſe colonies, to improve this commodity to the utmoſt of their power; and not to have ſo much regard to the quantity, as to the quality of it; for although the former may appear to have the advantage of the latter in point of profit, yet the goodneſs of every commodity muſt always claim the preference, and thereby will be found of more laſting advantage to the cultivator.

COIX. Lin. Gen. Plant. 927. Lachryma Jobi. Tourn. Inſt. R. H. 531. tab. 306. Job's Tears.

The CHARACTERS are,

It hath male and female flowers on the ſame plant; the male flowers are diſpoſed in a looſe ſpike; the chaff of theſe have two valves, incloſing two flowers, the valves are oblong and bearded; the petal has two oval valves, the length of the chaff, with narrow beards: theſe have each three hairy ſtamina, terminated by oblong four-cornered ſummits. There are a few female flowers ſituated at the baſe of the male ſpike in the ſame plant, theſe have bivalvular chaff; the valves are roundiſh, thick, and ſmooth; the petal hath two oval valves, the outer being larger and bearded at both ends. They have a ſmall oval germen, ſupporting a ſhort ſtyle divided into two parts, crowned by two horned ſtigmas which are longer than the flower, and covered with fine hairs; the germen afterward becomes a hard, roundiſh, ſmooth ſeed.

This genus of plants is ranged in the third ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Triandria. The plants of this claſs have male and female flowers on the ſame plant, and the flowers of this ſection have three ſtamina.

The SPECIES are,

1. COIX (*Lachryma Jobi*) ſeminibus ovatis. Hort. Cliff. 434. *Coix with oval ſeeds.* Lachryma Jobi. Cluſ. Hiſt. p. 2. *Job's Tears.*
2. COIX (*Angulatis*) ſeminibus angulatis. Hort. Cliff. 438. *Coix with angular ſeeds.* Lachryma Jobi Americana altiſſima, Arundinis folio & facie. Plum. Cat.

The firſt ſort grows naturally in the iſlands of the Archipelago, and is frequently cultivated in Spain and Portugal, where the poor inhabitants grind the grain to flour in a ſcarcity of corn, and make a coarſe ſort of bread of it.

This is an annual plant, which ſeldom ripen its ſeeds in England, unleſs the ſeaſon proves very warm; from a thick fibrous root is ſent out two or three jointed ſtalks, which riſe near three feet high, garniſhed with ſingle, long, narrow leaves at each joint, reſembling thoſe of the Reed; at the baſe of the leaves come out the ſpikes of flowers, ſtanding on ſhort foot-ſtalks; theſe ſpikes are compoſed of male flowers only, and below them is ſituated one or two female flowers; the male flowers decay ſoon after they have ſhed their farina; but the germen of the female flowers ſwell to a large oval ſeed, which is hard, ſmooth, and of a gray colour, greatly reſembling the ſeeds of Gromwel, from whence this plant has been by ſeveral writers titled Lithoſpermum.

Thoſe who are deſirous to cultivate this plant in England, may procure the ſeeds from Portugal, theſe ſhould be ſown on a moderate hot-bed in the ſpring, to bring the plants forward, and afterward tranſplant them on a warm border, allowing each two feet room at leaſt, and when the plants have taken root, they will require no farther care, but to keep them clean from weeds. Theſe will flower about Midſummer, and in warm ſeaſons, the ſeeds will ripen at Michaelmas. There is a variety of this with much broader leaves, which I received from Smyrna ſome years paſt, which did not perfect ſeeds here, ſo I cannot ſay whether it is only a variety, or a different ſort from this.

The ſecond ſort will grow to the height of ſeven or eight feet, and the ſtems become hard, like the Reed, or Indian Corn: theſe branch out, and produce ſeveral ſpikes of flowers; but this ſort will not live in the open air in England, therefore ſhould be plunged into the bark-ſtove, where it will live through the winter, and produce ripe ſeeds the ſecond year; and may be continued longer, if deſired.

COLCHICUM. Lin. Gen. Plant. 415. Tourn. Inſt. R. H. 348. tab. 181, 182. [So called from Colchos, a province of the Levant (now called Mingrelia, becauſe this plant was formerly very common in that place.] Meadow Saffron.

The CHARACTERS are,

The flower hath neither empalement or ſpatha; it hath one petal, riſing with an angular tube from the root, which is divided at the top into ſix oval, concave, erect ſegments; it hath ſix ſtamina which are ſhorter than the petal, terminated by oblong ſummits having four valves. The germen is ſituated in the root, ſupporting three ſlender ſtyles the length of the ſtamina, crowned by reflexed channelled ſtigmas; the germen afterward becomes a capſule with three lobes, having a ſeam on the inſide, dividing it into three cells, which contain ſeveral roundiſh rough ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſixth claſs, intitled Hexandria Trigynia, the flower having ſix ſtamina and three ſtyles.

The SPECIES are,

1. COLCHICUM (*Autumnale*) foliis planis lanceolatis, erectis. Hort. Cliff. 140. *Colchicum with plain, erect, ſpear-ſhaped leaves.* Colchicum commune. C. B. P. 67. *Common Meadow Saffron.*
2. COLCHICUM (*Montanum*) foliis linearibus, patentiſſimis. Lin. Sp. Plant. 342. *Meadow Saffron with very narrow ſpreading leaves.* Colchicum Montanum anguſtifolium. C. B. P. 68. *Narrow-leaved Mountain Meadow Saffron.*
3. COLCHICUM (*Variegatum*) foliis undulatis patentibus. Hort. Cliff. 140. *Meadow Saffron with waved ſpreading leaves.* Colchicum Chionenſe, floribus fritillariæ inſtar teſſulatis, foliis undulatis. Mor. Hiſt. 2. p. 341. *Meadow Saffron of Chios, with chequered flowers like Fritillary, and waved leaves.*
4. COLCHICUM (*Teſſulatum*) foliis planis patentibus. *Colchicum with plain ſpreading leaves.* Colchicum floribus fritillariæ inſtar teſſulatis, foliis planis. Mor. Hiſt. 2. p. 341. *Meadow Saffron, with chequered flowers like Fritillary, and plain leaves.*

There is a greater variety of theſe flowers than any here enumerated, which differ in the colour of their flowers, and other little accidents, which are not laſting, ſo muſt not be ranged as diſtinct ſpecies. But as many of them are cultivated in flower-gardens, I ſhall beg leave to mention thoſe varieties, which are frequently propagated by floriſts. Theſe are moſt of them ſeminal variations from the firſt ſort.

The moſt common Meadow Saffron hath a purpliſh flower.
The Meadow Saffron with white flowers.
Meadow Saffron with ſtriped flowers.
Broad-leaved Meadow Saffron.
Striped-leaved Meadow Saffron.
Many flowered Meadow Saffron.
Meadow Saffron with double purpliſh flowers.
Meadow Saffron with double white flowers.
Meadow Saffron with many white flowers.

The firſt ſort grows naturally both in the weſt and north of England. I have obſerved it in great plenty in the meadows near Caſtle Bromwich, in Warwickſhire, in the beginning of September. The country people call the flowers Naked Ladies, becauſe they come up naked, without any leaves or cover. This hath a bulbous root, about the ſize and ſhape of thoſe of the Tulip, but not ſo ſharp-pointed at the top, the ſkins or cover is alſo of a darker colour. Theſe bulbs are renewed every year, for thoſe which produce the flowers decay, and new roots are formed above. The flowers come out in autumn; theſe ariſe with long ſlender tubes from the root, about four inches high, ſhaped like thoſe of the Saffron, but larger; they are of a pale purple colour, and divided into ſix parts at the top, which ſtand erect; the number of flowers is generally in proportion to the ſize of the roots, from two to ſeven or eight: in March the green leaves appear, theſe are commonly four to a full grown root; they are folded over each other below, but ſpread open above ground, ſtanding croſs-ways: they are of a deep green, and when fully grown, are five or ſix inches long, and one and a half broad. The ſeed-veſſel comes out from between the leaves in April, and the ſeeds ripen in May, ſoon after which the leaves decay.

The other varieties of this, are ſuppoſed to have accidentally riſen from the ſeeds of this; ſo that thoſe who are deſirous to obtain a variety of theſe flowers, ſhould propagate them from ſeeds, by which method there may be a greater variety raiſed.

The ſecond ſort grows naturally on the mountains in Spain and Portugal. This hath a ſmaller root than the firſt, and a darker coat; the flowers appear in Auguſt or September; theſe are cut into ſix long narrow ſegments, of a reddiſh purple colour, having ſix yellow ſtamina. The leaves of this ſort come up ſoon after the flowers decay, and continue green all the winter, like the Saffron; theſe are long, narrow, and ſpread on the ground; in June theſe decay like the firſt ſort.

The third and fourth ſorts grow naturally in the Levant, but are commonly cultivated in the Engliſh gardens. Theſe flower at the ſame time as the firſt ſort, and the green leaves come up in the ſpring. The root of one of theſe ſpecies, is ſuppoſed to be the Hermodactyl of the ſhops.

Theſe are all very pretty varieties for a flower-garden, producing their flowers in autumn, when few other plants are in beauty; and are therefore, by ſome, called Naked Ladies. The green leaves come up in the ſpring, which are extended to a great length in May, then the green leaves begin to decay; ſoon after which time, is the proper ſeaſon to tranſplant their roots; for if they are ſuffered to remain in the ground till Auguſt, they will ſend forth freſh fibres; after which time it will be too late to remove them. The roots may be kept above ground until the beginning of Auguſt; at which time, if they are not planted, they will produce their flowers as they lie out of the ground, but this will greatly weaken their roots. The manner of planting their roots being the ſame as TULIPS, &c. I ſhall forbear mentioning it here, referring the reader to that article: and alſo for ſowing the ſeeds, by which means new varieties may be obtained, I ſhall refer to the article XIPHION; where will be proper directions for this work.

COLD ſignifies ſomething devoid of heat, or which does not contain in it any particles of fire; according to which definition, cold is a mere negative term. And this is agreeable to the ſentiments of moſt of our modern philoſophers, who ſuppoſe cold to conſiſt in a mere privation or diminution of heat.

Others much on the ſame principle, define cold, to be that ſtate of the minute parts of a body, wherein they are agitated more ſlowly and faintly than thoſe of the organs of feeling. And in this ſenſe, cold is a mere term of relation: and hence the ſame body becomes liable to be perceived hot or cold, as the particles of it are in greater or leſſer degree of motion than thoſe of the ſenſible organ.

Heat is ſuppoſed to conſiſt in a particular motion of the parts of the body; and hence the nature of cold, which is its oppoſite, is eaſily deducible; for we find that cold extinguiſhes, or rather abates heat. Whence it ſeems to follow, that thoſe bodies are cold, which check and reſtrain the motion of the particles, wherein heat conſiſts.

There are three kinds of bodies that can do this; viz. either thoſe whoſe particles are perfectly at reſt; or thoſe whoſe particles are indeed agitated, but with leſs violence than thoſe of the hot body to which they are applied; or, laſtly, ſuch whoſe particles have a motion proper for exciting the ſenſation of heat, but move with a different determination, ſo as to retard and change the motion of the particles of the organ.

Hence three different kinds of cold, or cold bodies, do proceed.

The 1ſt, That cold is common to all hard bodies; which conſiſts in the reſt of their parts.

The 2d is, That which riſes from plunging any part of the body in water; which conſiſts in this, that the parts of our præcordia, being more briſkly agitated than thoſe of the fluid, communicate part of their motion to it.

The 3d, The cold felt on the collection of warm air with a pan, or in blowing hot breath out of our mouth with the lips cloſe ſhut; which conſiſts in this, that the direct motion of the particles of air does, in ſome meaſure, change and rebate the motion and determination of the parts of the body: and hence it is, that a cold body cannot cool another without heating itſelf.

Hence alſo it proceeds, that the more the parts of a frigid body are at reſt, the more the particles of a warm body that is applied to heat them, muſt loſe of their motion, and conſequently of their heat.

Thus, there being more quieſcent parts in marble than in wood, which is full of pores and interſtices, the marble is felt colder than the wood: and hence alſo we may underſtand why air near marble, and other denſe bodies, feels ſomewhat colder than in other places.

On this principle the two latter kinds of cold appear ſomewhat more than privations: the particles inducing the cold may be eſteemed real frigorific corpuſcles; and coldneſs may be deemed a real quality, as well as hotneſs. Theſe particles do not only check the agitation of thoſe continually diffuſed from the inner parts of an animal to the outer; but having an elaſtic power, they bend, and hang about the filaments of the body, pinch and ſqueeze them; and hence is that acute pungent ſenſation called cold.

That cold is more than a mere relation or compariſon, is evident from its having real and poſitive effects; ſuch as freezing, congelation, condenſation, rarefaction, burſting, &c.

Dr. Clarke takes cold to be owing to certain nitrous and other ſaline particles, endued with particular figures proper to produce ſuch effects. Hence ſal-armoniac, ſalt petre, ſalt of urine, and many other volatile and alkalizate ſalts, mixed with water, increaſe its degree of cold very ſenſibly.

Hence alſo comes that popular obſervation, that cold prevents corruption; which, however, muſt not be admitted without an exception; ſince if an hard porous body have its interſtices filled with water, and this be too much dilated by freezing, the including body will be burſt. And thus it is that cold proves deſtructive to the parts of ſome plants: as it happened in the winters, anno 1728, and 1739-40, in ſeveral trees, whoſe trunks were much expoſed to the ſouth-weſt, the ſap being thereby rarefied by the warmth of the ſun, which, for ſeveral days, at the beginning of the ſevere froſt, ſhone with an uncommon heat, and the nights coming on to extreme cold, whereby the rarefied ſap was ſo ſuddenly condenſed, that the ſap-veſſels could not contain it, and thereby burſt off the bark of many trees almoſt from top to bottom; and this chiefly on the ſouth-weſt ſide of the trees; as it did of ſeveral large trees in the phyſic-garden at Chelſea; and ſeveral Pear, and other fruit-trees, in the nurſeries of Mr. Francis Hunt at Putney, &c. And thus it is that great quantities of trees are rendered ſhaken, and the timber, when cut, of little value; which is generally the caſe in very ſevere winters. In the hard froſt of the year 1739-40, there was great damage done to the Oak-timber in moſt parts of England, by the froſt penetrating to the ſap-veſſels of the trees; and by freezing the ſap, the veſſels could not contain it, but burſt with great noiſe; ſo that the woods reſounded with a noiſe ſomewhat like the breaking down of the branches of trees, when they are lopping.

Dr. Boerhaave ſays, That there is no ſuch thing in all nature as abſolute cold; that the moſt ſevere he had ever known, was in the year 1728, that then the water would freeze while it ran down his hand; and yet even then the cold was not ſo complete, but that he could make an artificial cold greater by twelve degrees.

Though much might be ſaid as to the effects of cold on plants, I ſhall only conclude with an obſervation of the Reverend Dr. Hales, who, in the concluſion of his excellent treatiſe of Vegetable Statics, ſays; The conſiderable quantity of moiſture, which is perſpired from the branches of trees during the cold winter ſeaſon, plainly ſhews the reaſon why, in a long ſeaſon of cold north-eaſterly winds, the bloſſoms, and tender young-ſet fruit and leaves, are, in the early ſpring, ſo frequently blaſted, viz. by having the moiſture exhaled faſter than can be ſupplied from the trees; for, doubtleſs, moiſture riſes ſlower from the root, the colder the ſeaſon is, though it riſes, in ſome degree, all the winter; as is evident, as he ſays, from his ſixteenth experiment in the ſaid book.

And from the ſame cauſe it is, that the leafy ſpires of Corn are by theſe cold drying winds often faded, and turned yellow; which makes the huſbandman, on theſe occaſions, wiſh for ſnow: which, though it be very cold, yet it not only defends the root from being frozen, but alſo ſcreens the Corn from theſe drying winds, and keeps it in a moiſt, florid, ſupple ſtate.

It ſeems therefore to be a reaſonable direction, which ſome authors, who write on agriculture and gardening give, viz. During theſe cold drying winds, when little dew falls, to water the trees in dry ſoils, in the bloſſoming ſeaſon, and while the young-ſet fruit is tender; and provided there is no immediate danger of a froſt, or in caſe of continued froſt, to take care to cover the trees well, and at the ſame time to ſprinkle them with water; which is imitating nature's method of watering every part.

As to ſloping ſhelters over wall-trees he ſays; I have often found, that when they are ſo broad, as to prevent any rain or dew coming at the trees, they do more harm than good in theſe long eaſterly drying winds, becauſe they prevent the rain and dews falling on them; which would not only refreſh and ſupple them, but alſo nouriſh them: but in caſe of ſharp froſt after a ſhower of rain, theſe ſhelters and other fences muſt needs be of excellent uſe to prevent the almoſt total deſtruction occaſioned by the freezing of the tender parts of vegetables, when they are ſaturated with moiſture.

COLDENIA. Lin. Gen. Plant. 159. This plant was ſo titled by Dr. Linnæus, in honour of Dr. Colden, of North America, who is a very curious botaniſt, and has diſcovered ſeveral new plants which were not known before.

The Characters are,

The empalement of the flower is compoſed of four erect leaves, which are as long as the petal. It hath a funnel-ſhaped flower of one petal, ſpreading at the top, and obtuſe; it hath four ſtamina, which are inſerted in the tube of the petal, terminated by roundiſh ſummits. In the center is ſituated four oval germen, each ſupporting a hairy ſtyle the length of the ſtamina, crowned by permanent ſtigmas. The germen afterward become an oval, compreſſed, rough fruit, with four cells, terminated by four beaks, incloſed by the empalement, each of the cells containing a ſingle ſeed, convex on one ſide, and angular on the other.

This genus of plants is ranged in the third ſection of Linnæus's fourth claſs, intitled Tetrandria Tetragynia, the flower having four ſtamina and four ſtyles.

There is but one Species of this genus, viz.

Coldenia (*Procumbens*). Flor. Zeyl. 79. This is by Dr. Pluknet titled, Teucrii facie biſnagarica tetracoccos roſtrata. Alm. 363.

This is a native of India, from whence the ſeeds have been brought to ſome of the curious botanic gardens. It was ſent me by Dr. Linnæus, profeſſor of botany at Upſal in Sweden. It is an annual plant, whoſe branches trail on the ground; they extend near a foot from the root, and divide into many ſmaller branches, garniſhed with ſhort leaves, ſitting cloſe to them; theſe are deeply crenated on their edges, and have ſeveral longitudinal veins; they are of a glaucous colour, and come out without order. The flowers are produced at the wings of the leaves, growing in ſmall cluſters; theſe have one funnel-ſhaped petal cut into four ſegments at the top; they are of a pale blue colour, and very ſmall; they have four ſtamina and four ſtyles, having hairy ſtigmas. When the flower decays, the germen becomes a fruit, compoſed of four cells, wrapped up in the empalement, each containing a ſingle ſeed.

This plant is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring; and when the plants are fit to remove, they ſhould be each put into a ſeparate ſmall pot, plunged into a hot-bed of tanners bark, obſerving to ſhade them till they have taken freſh root; after which they ſhould have air admitted to them every day in proportion to the warmth of the ſeaſon, and gently watered two or three times a week in warm weather, but they muſt not have too much moiſture. Theſe plants muſt remain in the hot-bed, where they will flower in June, and the ſeeds will ripen in September.

COLEWORTS. See Brassica.

COLLINSONIA. Lin. Gen. Plant. 38. The title of this plant was given to it by Dr. Linnæus, in honour of Mr. Peter Collinſon, F. R. S. a moſt diſtinguiſhed promoter of botanical ſtudies, and the firſt who introduced this plant, among many others, to the Engliſh gardens.

The Characters are,

The flower hath a permanent empalement of one leaf, cut into five equal ſegments at the top, the three upper being reflected, and the two under erect. The flower is funnel ſhaped, of one petal which is unequal, and much longer than the empalement, cut into five parts at the top, the upper being ſhort and obtuſe, two of them being reflexed; the lower lip or beard is longer, ending in many points. It hath two long briſtly ſtamina which are erect, terminated by incumbent ſummits. It hath a quadrifid obtuſe germen, with a large gland, ſupporting a briſtly ſtyle the length of the ſtamina, crowned by a pointed bifid ſtigma. The germen afterward becomes a ſingle roundiſh ſeed, ſituated in the bottom of the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, intitled Diandria Monogynia, the flower having two ſtamina and one ſtyle.

We have but one Species of this plant, viz.

Collinsonia (*Canadenſis*) foliis cordatis oppoſitis. *Collinſonia with heart-ſhaped leaves growing oppoſite.*

This plant was brought from Maryland, where it grows wild, as it alſo does in many other parts of North America, by the ſides of ditches, and in low moiſt ground, where it uſually riſes to the height of four or five feet; but in England it ſeldom grows above three feet high, and unleſs it be planted in a moiſt warm ſituation, or in dry weather is duly watered, it rarely flowers well; therefore many people keep the plants in large pots, for the more convenient watering them, but theſe plants ſeldom produce good ſeeds; whereas thoſe which are planted in the full ground, and are conſtantly watered, will ripen ſeeds very well in good ſeaſons.

This hath a perennial root. The ſtalks decay in the autumn, and freſh ſhoots come out in the ſpring. The ſtalks are ſquare, garniſhed with heart-ſhaped leaves, placed oppoſite, which are ſawed on their edges. The flowers are produced at the extremity of the ſtalks in looſe ſpikes; theſe have long tubes, and are divided into five parts at the top; they are of a purpliſh yellow, and the lower ſegment is terminated by long hairs. The flowers appear in July, and the ſeeds ripen in autumn.

This plant may be eaſily propagated by parting the roots in October. Theſe roots ſhould be planted at three feet diſtance, for they require much nouriſhment, otherwiſe they will not thrive. This plant will live in the open ground, if it is planted in a ſheltered ſituation.

COLOCASIA. See Arum.

COLOCYNTHIS. See Cucurbita.

COLUMBINE. See Aquilegia.

COLUMNEA. Plum. Nov. Gen. 28. tab. 33. Lin. Gen. Plant. 710. The title of this genus was given to it by Plumier, in honour of Fabius Columna, a nobleman of Rome, who has publiſhed two curious books of botany.

The Characters are,

The flower hath a permanent empalement of one leaf, cut into five parts at the top; it hath one petal, of the (ringent) or grinning kind, having a long ſwelling tube, divided above into two lips, the upper being erect, concave, and entire; the lower is divided into three parts which ſpread open: it hath four ſtamina, two being longer than the other; theſe are incloſed in the upper lip, and are terminated by ſingle ſummits. In the center is ſituated the roundiſh germen, ſupporting a ſlender ſtyle, crowned by a bifid acute ſtigma. The germen afterward becomes a globular berry with two cells, ſitting on the empalement, and is of the ſame magnitude, containing ſeveral oblong ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia. The flowers of this claſs have two long and two ſhort ſtamina, and thoſe of this ſection have their ſeeds incloſed in a capſule.

We have but one Species of this plant in the Engliſh gardens, viz.

Columnea (*Scandens*). Lin. Sp. Plant. 638. Columnea ſcandens, Phœniceo flore, fructu albo. Plum. Nov. Gen. 28. *Climbing Columnea with a ſcarlet flower and a white fruit.* Plumier mentions a variety of this, with a yellowiſh flower and a white fruit. But this is only a ſeminal variation ſuppoſed to have accidentally riſen from the ſeeds of the firſt.

I received ſeeds of the ſcarlet ſort from Carthagena in New Spain, where the plants grew naturally. This hath a climbing ſtalk, which faſtens itſelf to the neighbouring plants, whereby it is ſupported. The leaves are oval, ſawed on their edges, and ſtand upon ſhort foot-ſtalks; theſe, and alſo the ſtalks, are very hairy; but the plants decayed the following year, before they produced any flowers, ſo that I can give no deſcription of them.

Theſe plants are natives of the warmeſt parts of America, ſo are too tender to live in England, unleſs they are preſerved in the ſtove; they are propagated by ſeeds, which muſt be ſown in a good hot-bed; and when the plants come up, they muſt be treated in the ſame way as other tender exotic plants which are kept in the bark-ſtove.

COLUTEA. Tourn. Inſt. R. H. 649. tab. 417. Lin. Gen. Plant. 776. Bladder Sena.

The CHARACTERS are,

It hath a bell-ſhaped permanent empalement of one leaf, indented in five parts. The flower is of the butterfly kind. The ſtandard, wings, and keel, vary in their figure in different ſpecies. It hath ten ſtamina, nine of which are joined, the other ſtands ſeparate, which are terminated by ſingle ſummits. In the center is ſituated an oblong germen, which is compreſſed, ſupporting a riſing ſtyle, crowned by a bearded line, extended from the middle of the upper part of the ſtyle. The germen afterward becomes a broad ſwollen pod with one cell, including ſeveral kidney-ſhaped ſeeds.

This genus of plants is ranged in Linnæus's third ſection of his ſeventeenth claſs, intitled Diadelphia Decandria. The flowers of this claſs have ten ſtamina, nine of which are joined, and the tenth ſtands ſeparate.

The SPECIES are,

1. COLUTEA (*Arboreſcens*) arborea, foliolis obcordatis. Hort. Cliff. 365. *Tree Bladder Sena with heart-ſhaped lobes.* Colutea veſicaria. C. B. P. 396. *Common Bladder Sena.*
2. COLUTEA (*Iſtria*) foliolis ovatis, integerrimis, caule fruticoſo. *Shrubby Bladder Sena with oval leaves which are entire.*
3. COLUTEA (*Orientalis*) foliolis cordatis minoribus, caule fruticoſo. *Bladder Sena with ſmaller heart-ſhaped leaves, and a ſhrubby ſtalk.* Colutea Orientalis flore ſanguineâ coloris, luteâ maculâ notato. Tourn. Cor. 44.
4. COLUTEA (*Fruteſcens*) fruticoſa foliolis ovato-oblongis. Hort. Cliff. 366. *Shrubby Bladder Sena with oblong oval leaves.* Colutea Æthiopica flore Phœniceo, folio Barbæ Jovis. Breyn. Cent. 1. 73. *Æthiopian Bladder Sena with a ſcarlet flower.*
5. COLUTEA (*Americana*) foliolis ovatis, emarginatis, leguminibus oblongis compreſſis acuminatis, caule arboreo. *Bladder Sena with oval leaves indented at the top, oblong, compreſſed, pointed pods, and a tree-like ſtalk.* Colutea Americana, veſiculis oblongis compreſſis. Houſt. MSS. *American Bladder Sena with oblong compreſſed pods.* Dr. Pluknet titles it Colutea Veræ Crucis veſicaria. Alm. 111. pl. 165. f. 3. *Bladder Sena of Vera Cruz.*
6. COLUTEA (*Herbacea*) herbacea foliolis linearibus. Hort. Upſal. 266. *Herbaceous Bladder Sena with narrow leaves.* Colutea Africana annua, foliolis parvis, mucronatis, veſiculis compreſſis. Hort. Amſt. 2. p. 87. tab. 44.
7. COLUTEA (*Procumbens*) caulibus procumbentibus, foliolis ovato-linearibus, tomentoſis, floribus alaribus pedunculis longiſſimis. *Bladder Sena with trailing ſtalks, oval narrow leaves which are woolly, and flowers growing from the ſides of the ſtalks, with very long foot-ſtalks.*

The firſt ſort is commonly cultivated in the nurſery-gardens, as a flowering ſhrub, to adorn plantations. This grows naturally in Auſtria, in the ſouth of France and Italy, from whence the ſeeds were originally brought to England; this hath ſeveral woody ſtems, which grow to the height of twelve or fourteen feet, ſending out many woody branches, garniſhed with winged leaves, compoſed of four or five pair of oval lobes, placed oppoſite, terminated by an odd one; theſe are indented at the top in form of a heart, and are of a grayiſh colour. The flowers come out from the wings of the leaves upon ſlender foot-ſtalks, about two inches long, each ſuſtaining two or three flowers of the butterfly kind, whoſe ſtandard is reflexed and large. The flowers are yellow, with a dark-coloured mark on the petal; theſe are ſucceeded by inflated pods an inch and a half long, having a ſeam on the upper ſide, containing a ſingle row of kidney-ſhaped ſeeds, faſtened to a placenta. This flowers in June and July, and the ſeeds ripen in autumn. There is a variety of this with reddiſh pods, which is equally common in the gardens, and is ſuppoſed to be only an accidental variety, for the plants do not differ in any other part.

The ſeeds of the ſecond ſort were brought from the Levant by the Reverend Dr. Pocock, which ſucceeded in the garden at Chelſea; and ſince Dr. Ruſſel, who reſided many years at Aleppo, brought over dried ſamples of this ſort, which he aſſures me grow common near that city. This ſort ſeldom grows more than ſix or ſeven feet high; the branches are very ſlender, and ſpread out on every ſide, garniſhed with winged leaves, compoſed of nine pair of ſmall, oval, entire lobes, terminated by an odd one; the flowers ſtand upon ſlender foot-ſtalks, about the ſame length of the former. The flowers are alſo like thoſe, but are of a brighter yellow. This ſort begins to flower early in May, and continues flowering till the middle of October.

The third ſort was diſcovered by Dr. Tournefort in the Levant, from whence he ſent the ſeeds to the royal garden at Paris, where they ſucceeded, and ſince have been communicated to moſt of the curious gardens in Europe. This hath a woody ſtem, which ſends out many branches on every ſide, which do not riſe above ſeven or eight feet high; theſe are not ſo ſtrong as thoſe of the firſt ſort, and are garniſhed with winged leaves, compoſed of five or ſix pair of ſmall heart-ſhaped lobes, terminated by an odd one. The flowers proceed from the ſide of the branches, ſtanding upon foot-ſtalks, each ſuſtaining two or three flowers, ſhaped like thoſe of the firſt ſort, but ſmaller; they are of a dark red colour, marked with yellow: theſe appear in June, and the ſeeds ripen in autumn.

The fourth ſort grows naturally in Æthiopia, from whence the ſeeds were brought to Europe. This hath a weak ſhrubby ſtalk, which ſends out ſide branches, growing erect, garniſhed with equal winged leaves, compoſed of ten or twelve pair of ſmall, oval, oblong, hoary lobes. The flowers are produced at the upper part of the branches from the wings of the leaves, each foot-ſtalk ſuſtaining three or four ſcarlet flowers, which are longer than thoſe of the other ſorts, and are not reflexed; theſe are ſucceeded by inflated pods, containing one row of kidney-ſhaped ſeeds. The uſual time of this plant producing its flowers is in June; but when the ſeeds are ſown early in the ſpring, the plants frequently flower the following autumn.

The fifth ſort was ſent me from La Vera Cruz, in New Spain, in the year 1730, by the late Dr. Houſtoun. This hath a ſhrubby ſtalk, which riſes to the height of twelve or fourteen feet, ſending out many branches, garniſhed with winged leaves, compoſed of three pair of oval lobes, terminated by an odd one; theſe are indented at the top, and are of a light green. The flowers are of a bright yellow, and ſtand two or three upon each foot-ſtalk, and are ſucceeded by compreſſed winged pods near four inches long, which end in long points.

The ſixth ſort grows naturally at the Cape of Good Hope. This is an annual plant of little beauty, ſo is rarely cultivated but in botanic gardens for the ſake of variety. It riſes with a ſlender herbaceous ſtalk about a foot and a half high, dividing upward into three or four branches, garniſhed with winged leaves, compoſed of five or ſix pair of very narrow lobes an inch long, which are a little hoary. The flowers are ſmall, of a purpliſh colour, ſtanding three together on ſlender foot-ſtalks, which are ſucceeded by flat oval pods, each containing two or three kidney-ſhaped ſeeds. It flowers in July, and the ſeeds ripen in autumn, and the plant decays ſoon after.

The ſeeds of the ſeventh ſort were ſent me from the Cape of Good Hope, in 1753, which have ſucceeded in the garden at Chelſea. This plant hath many ſlender ligneous ſtalks, which trail on the ground, and are divided into many ſmaller branches, garniſhed with winged leaves, compoſed of twelve or fourteen pair of ſmall, narrow, oval lobes, terminated by an odd one; theſe, and alſo the ſtalks, are covered with a whitiſh down. The flowers are very ſmall, of a purple colour, and ſtand upon very long ſlender footſtalks, each ſuſtaining three or four flowers; theſe are ſucceeded by compreſſed pods little more than half an inch long, which are a little bent like a ſickle, each containing a ſingle row of ſmall kidney-ſhaped ſeeds. It flowers in June and July, and the ſeeds ripen in autumn. This is a perennial plant, which, if ſheltered in the winter, will continue ſeveral years; but the branches do not extend more than a foot in length, and unleſs they are ſupported, always trail upon the ground.

The three firſt mentioned ſorts are very hardy ſhrubs, which thrive in the open air extremely well, ſo are generally propagated for ſale in the nurſery-gardens; but the firſt ſort hath been longer in England, ſo is more generally known and propagated than either of the other, which have been but few years in the Engliſh gardens, nor has the third ſort been long known in this country. This is not mentioned in any of the botanic books; but as the ſeeds ripen here very well, in a few years it may be in as great plenty as the firſt ſort.

The three firſt ſorts are propagated by ſowing their ſeeds any time in the ſpring, in a bed of common earth; and when the plants are come up, they muſt be kept clear from weeds; and the Michaelmas following they ſhould be tranſplanted either into nurſery rows, or in the places where they are deſigned to remain; for if they are let grow in the ſeed-bed too long, they are very ſubject to have downright tap-roots, which renders them unfit for tranſplantation; nor ſhould theſe trees be ſuffered to remain too long in the nurſery before they are tranſplanted, where they are to remain for the ſame reaſon.

The firſt ſort will grow to the height of twelve or fifteen feet, ſo is very proper to intermix with trees of a middling growth in wilderneſs quarters; or in clumps of flowering trees, where the oddneſs of their flowers and pods will make a pretty variety, eſpecially as theſe trees continue a long time in flower; for they uſually begin flowering by the end of May, and from that time to September they are ſeldom deſtitute of flowers, but eſpecially the ſecond ſort.

Theſe ſhrubs make great ſhoots annually, which are frequently broken down by ſtrong winds in the ſummer; ſo that if they are not ſheltered by other trees, their branches ſhould be ſupported, otherwiſe they will be broken and ſplit off, whereby the trees will be rendered unſightly.

The third ſort does not grow ſo tall as the common, but makes a more regular ſhrub and is leſs liable to ſplit. The flowers of this ſort are of a duſky red colour, ſpotted with yellow, ſo it makes a very pretty variety, and is as hardy as the common ſort, therefore may be propagated by ſeeds in the ſame manner.

The fourth ſort is tender, ſo will not live through the winters (when they are ſevere) in the open air in England; but in mild winters, if they are planted in a dry ſoil and a warm ſituation, they will thrive very well; and thoſe plants which live abroad will flower much ſtronger, and make a finer appearance, than thoſe which are preſerved in the green-houſe; for theſe plants require a large ſhare of air, otherwiſe they are apt to draw up weak, ſo ſeldom produce their flowers in plenty; therefore when any of the plants are ſheltered in winter, they muſt be placed as near the window as poſſible, that they may have all the advantages of air; and in the ſpring they muſt be hardened, to bear the open air as ſoon as poſſible.

This ſort is propagated by ſeeds as the former. If the ſeeds are ſown early in the ſpring upon a warm border of light earth, the plants will flower in Auguſt; and, if the autumn proves favourable, they will ſometimes ripen their ſeeds very well; but there are ſome perſons who ſow the ſeeds upon a moderate hot-bed in the ſpring, whereby they bring their plants ſo forward as to flower in July, whereby the ſeeds are generally perfected from theſe plants. When the plants are tranſplanted, it ſhould always be done while they are young, for they do not bear removing when they are large. This ſort will ſometimes live in the open air for three or four years, when they ſtand in a well ſheltered ſituation; and theſe will grow to have large heads, and make a very fine appearance when they are in flower; they will alſo continue much longer in beauty than thoſe plants which are treated more tenderly.

The fifth ſort grows naturally in warm countries, ſo is too tender to thrive in the open air in England. It is propagated by ſeeds, which muſt be ſown on a hot-bed in the ſpring; and when the plants are two inches high, they ſhould be each tranſplanted into a ſeparate ſmall pot filled with light earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them till they have taken freſh root; after which they muſt be treated in the ſame way as other plants from the ſame climate, always keeping them in a ſtove, which ſhould be of a moderate temperature of heat.

The ſixth ſort is a low annual plant, which ſeldom grows more than a foot and a half in height; the flowers being ſmall, and having little beauty, it is ſeldom preſerved but in botanic gardens. The ſeeds of this ſort muſt be ſown upon a moderate hot-bed in the ſpring, and the plants muſt be planted into ſmall pots, and brought forward in another hot-bed. In July they will flower, when they may be expoſed in the open air, in a warm ſituation, where the ſeeds will ripen in September, and the plants will ſoon after decay.

The ſeventh ſort may be raiſed on a moderate hot-bed in the ſpring, and afterward expoſed to the open air in ſummer; but in winter they muſt be ſheltered under a frame, otherwiſe the froſt will deſtroy them.

COLLIFLOWER. See Brassica.

COLUTEA SCORPIOIDES. See Emerus.

COMA AUREA. See Chrysocoma.

COMARUM. Lin. Gen. Plant. 563. Pentaphylloides. Tourn. Inſt. R. H. 298. Marſh Cinquefoil.

The Characters are,

The flower hath a large ſpreading empalement of one leaf, divided into ten parts at the top, which is coloured. It hath five oblong petals, which are inſerted in the empalement, but are much ſmaller. It hath twenty or more permanent ſtamina, which are inſerted into the empalement, terminated by moon-ſhaped ſummits. It hath a great number of ſmall roundiſh germen collected into a head, having ſhort ſingle ſtyles ariſing from their ſides, which are crowned by ſingle ſtigmas. The common receptacle afterward becomes a large fleſhy fruit, having many pointed ſeeds adhering to it.

This genus of plants is ranged in the fifth ſection of Linnæus's twelfth claſs, intitled Icoſandria Polygynia, the flower having many ſtamina and a great number of ſtyles.

We know but one Species of this genus, viz.

Comarum (*Paluſtre*). Fl. Lapp. 214. Pentaphylloides paluſtre rubrum. Inſt. R. H. 298. *Red Marſh Baſtard Cinquefoil*; and the Quinquefolium paluſtre rubrum. C. B. P. 326. *Red Marſh Cinquefoil.*

There is another variety of this, which grows plentifully in Ireland, and alſo in ſeveral places in the north of England, from whence I have procured many of the plants, which after one year's growth in the garden, have been ſo like the common ſort, as not to be diſtinguiſhed from it; ſo that the different appearance which it has in the places where it grows noturally, may be ſuppoſed to ariſe from the ſoil and ſituation. This is by Dr. Plukenet titled Pentaphyllum paluſtre rubrum, craſſis & villoſis foliis Suecicum & Hibernicum. Alm. 284. *Red Marſh Cinquefoil of Sweden and Ireland, with thick and hairy leaves.*

This plant hath creeping woody roots, which ſend out many black fibres, penetrating deep into the ground, from which ariſe many herbaceous ſtalks about two feet high, which generally incline to the ground; theſe are garniſhed at each joint with one winged leaf, compoſed of five, ſix, or ſeven lobes, which riſe above each other, the middle being the largeſt; the lower diminiſhing, and with their baſe embrace the ſtalks; theſe are deeply ſawed on their edges, ſmooth above, of a light green, and hoary on their under ſide. The flowers are produced at the top of the ſtalks, three or four together on ſhort foot-ſtalks; theſe have a large ſpreading empalement, which is red on the upper ſide, and divided at the top into ten parts; in the center ſits the five petals, which are red, and not more than a third part the ſize of the empalement; within theſe are ſituated many germen, attended by twenty or more ſtamina, terminated by dark ſummits. After the flower is paſt, the receptacle which ſits in the bottom of the empalement, becomes a fleſhy fruit, ſomewhat like a Strawberry, but flatter, including a great number of pointed ſeeds. It flowers in July, and the ſeeds ripen in autumn.

As theſe plants are natives of bogs, they are with difficulty preſerved in gardens, for they muſt be planted in a ſoil as near to that of their natural growth as poſſible; they are very apt to ſpread much at the root, when in a proper ſituation: ſo whoever is inclinable to preſerve theſe plants, may remove them from the places of their growth in October; and if they are planted on a bog, there will be no danger of the plants ſucceeding. There are a few of theſe plants now growing upon a bog at Hampſtead, which were planted there ſome years ago; but the neareſt place to London, where they grow wild in plenty, is in the meadows near Guilford in Surry.

COMMELINA. Lin. Gen. Plant. 58. Plum. Nov. Gen. 48. tab. 38. Zanonia. Plum. Nov. Gen. 38. tab. 38. This plant was ſo called by father Plumier, from Dr. Commeline, a famous profeſſor of botany at Amſterdam.

The Characters are,

It hath a permanent ſpatha, which is large, heart-ſhaped, compreſſed, and ſhut together. The flower hath ſix concave petals, three or four of which are ſmall and oval, (*theſe are frequently taken for the empalement*) *the other are large, roundiſh, and coloured. It hath three nectariums,* (*which have been ſuppoſed to be ſtamina;*) *theſe have proper ſtamina, which ſit horizontal, and are ſhaped like a croſs. There are three awl-ſhaped ſtamina, which recline, and ſit about thoſe of the nectarium, which are terminated by oval ſummits. In the center is ſituated a roundiſh germen, ſupporting a twining ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a naked globular capſule, with three furrows, having three cells, each containing two angular ſeeds.*

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, the flower having three ſtamina and one ſtyle; to this genus he has joined the Zanonia of Plumier, which was ſeparated by that author from Commelina, becauſe the flower has three petals, and his Commelina but two; whereas the ſeveral ſpecies of this genus moſt of them differ in the number of their petals, ſome having two green, and four coloured petals, others are equal, and ſome have four green, and but two coloured petals.

The Species are,

1. Commelina (*Communis*) corollis inæqualibus, foliis ovato-lanceolatis, acutis, caule procumbente, glabro. Hort. Upſal. 18. *Commelina with unequal petals, oval, ſpear-ſhaped, pointed leaves, and a ſmooth trailing ſtalk.* Commelina procumbens annua, ſaponariæ folio. Hort. Elth. 93. tab. 78.
2. Commelina (*Erecta*) corollis inæqualibus, foliis ovato-lanceolatis, caule erecto, ſcabro, ſimpliciſſimo. Hort. Upſal. 18. *Commelina with unequal petals, oval ſpear-ſhaped leaves, and a ſingle, upright, rough ſtalk.* Commelina erecta, ampliore ſubcæruleo flore. Hort. Elth. 94. tab. 78.
3. Commelina (*Africana*) corollis inæqualibus, foliis lanceolatis, glabris, obtuſis, caule repente. Lin. Sp. Plant. 41. *Commelina with unequal petals, ſmooth, ſpear-ſhaped, obtuſe leaves, and a creeping ſtalk.* Commelina procumbens, flore luteo. Prod. Leyd. 538.
4. Commelina (*Tuberoſa*) corollis æqualibus, foliis ovato-lanceolatis, ſubcilliatis. Hort. Upſal. 18. *Commelina with equal petals, and oval ſpear-ſhaped leaves, which are hairy on their under ſide.* Commelina radice anacampſerotidis. Hort. Elth. 94. tab. 79.
5. Commelina (*Zanonia*) corollis æqualibus, pedunculis incraſſatis, foliis lanceolatis, vaginis laxis margine hirſutis bracteis geminis. Lin. Sp. Plant. 61. *Commelina with equal petals, thick foot-ſtalks to the flower, ſpear-ſhaped leaves, a looſe hood, and double bractea.* Zanonia graminea perfoliata. Plum. Nov. Gen. 38.

There are ſome other ſpecies of this genus, but thoſe which are here enumerated, are all that I have ſeen growing in the Engliſh gardens.

The firſt ſort grows naturally in the iſlands in the Weſt-Indies, and alſo in Africa; this is an annual plant, which hath ſeveral trailing ſtalks, that put out roots at the joints, which ſtrike into the ground; at each joint is placed one oval ſpear-ſhaped leaf, ending in a point, embracing the ſtalk with its baſe, and hath ſeveral longitudinal veins: they are of a deep green, and ſmooth. The flowers come out from the boſom of the leaves, included in a ſpatha, which is compreſſed and ſhut up, each having two or three flowers, ſtanding upon ſhort foot-ſtalks, compoſed of two large blue petals, and four ſmall green ones, which have generally been termed the empalement of the flower; within theſe are ſituated three nectariums, each having a ſlender ſtamina fixed on the ſide; theſe ſurround the germen, which afterward becomes a roundiſh capſule having three cells, in each of theſe is lodged two angular ſeeds. It flowers in June and July, and the ſeeds ripen in autumn. This plant was titled Ephemeron flore dipetalo, by ſome of the older writers on botany.

The ſecond ſort grows naturally in Penſylvania, from whence I received the ſeed; this hath a perennial root, compoſed of many white fibres; the ſtalks riſe a foot and a half high, are upright, rough, herbaceous, and about the ſize of quills; theſe have a ſingle leaf at each joint, ſhaped like thoſe of the firſt ſort, and embrace the ſtalks with their baſe; the flowers come out from the boſom of the leaves at the upper part of the ſtalk, ſitting upon ſhort foot-ſtalks; they are of a pale bluiſh colour, and are ſucceeded by ſeeds as the firſt ſort. This flowers about the ſame time with the firſt, but the ſeeds do not often ripen in England.

The third ſort grows naturally in Africa; this hath a fibrous root, which ſends out many trailing ſtalks three feet long, which ſend out roots at every joint, and from them many more ſhoots are produced; ſo that where the plants are in a proper degree of warmth, and have room to ſpread, they will cover a large ſurface of ground. The leaves of this ſort are very like thoſe of the firſt, but the flowers are larger and of a deep yellow colour; the petals of this are heart-ſhaped, and the ſeed-veſſels are larger. This flowers in July, and the ſeeds ripen in autumn.

The fourth ſort grows naturally near Old Vera Cruz in New Spain, from whence the ſeeds were ſent me by the late Dr. Houſtoun. This hath a thick fleſhy root compoſed of ſeveral tubers, ſomewhat like thoſe of Ranunculus, ſeveral joining together at the top, where they form a head, and diminiſh gradually downward; from this ariſe one or two inclining ſtalks, which ſend out ſide branches from their lower parts; theſe are garniſhed with oval ſpear-ſhaped leaves, part of which have long foot-ſtalks, the others embrace the ſtalks with their baſe; they have ſhort hairs on their under ſide, and toward the ſtalk, but are ſmooth above, of a deep green colour, and cloſe every evening, or in cold weather. The flowers are produced toward the upper part of the ſtalks, from the boſom of the leaves, ſtanding upon ſlender foot-ſtalks; theſe are compoſed of three blue petals which are pretty large and roundiſh, and three ſmaller which are green; the ſeeds are like thoſe of the other ſorts. It flowers in June, July, and Auguſt, and the ſeeds ripen in autumn, ſoon after which the ſtalks decay, but the roots may be preſerved two or three years, if they are planted in a ſtove in winter.

The fifth ſort grows naturally in the Weſt-Indies; the ſeeds of this were ſent me from the iſland of Barbuda. This hath trailing ſtalks like the firſt, which are garniſhed with narrow graſſy leaves, embracing the ſtalks with their baſe; the flowers are produced at the end of the ſtalks, upon thick foot-ſtalks, three flowers generally ſitting on each. The flowers have three equal large petals of a ſky blue, and three ſmaller which are green. Theſe flower in July and Auguſt, but have not perfected ſeeds in England.

All the ſorts are propagated by ſeeds; the firſt will grow if ſown in the full ground; but if the ſeeds are ſown upon a warm border of light earth in autumn, the plants will riſe early in the ſpring; ſo from theſe goods ſeeds may be expected, if the ſeaſon proves favourable; whereas thoſe which are ſown in the ſpring, often lie long in the ground, ſo rarely ripen their ſeed. Theſe plants have but little beauty, ſo that two or three of each ſort, is as many as moſt people chooſe to have; therefore if the ſeeds are ſown in autumn where the plants are deſigned to remain, or the ſeeds permitted to ſcatter, the plants will require no farther care, but to keep them clear from weeds.

The ſecond ſort hath a perennial root; this ſeldom ripens ſeeds in England, but the roots ſend out offſets, by which the plant is eaſily propagated. But it is too tender to live in the full ground in winter, unleſs it has a warm ſheltered ſituation; therefore ſhould be planted in pots, and ſheltered under a common frame in winter, and expoſed abroad in ſummer; the beſt time to tranſplant and part theſe roots is about the end of March.

The other ſorts are tender, ſo their ſeeds muſt be ſown on a moderate hot-bed in the ſpring, and when the plants are two inches high, they ſhould be tranſplanted to a freſh hot-bed to bring the plants forward; when they have taken freſh root, they ſhould have a large ſhare of freſh air admitted to them every day in warm weather, to prevent their growing weak; and in June theſe may be carefully taken up, and tranſplanted on a warm border of light earth, obſerving to ſhade them till they have taken freſh root; after which they will require no other care, but to keep them clean from weeds. With this management the plants will flower and produce good ſeeds.

The third and fourth ſorts may be continued, if they are planted in pots, and in autumn placed in the bark-ſtove; or if the roots of the fourth ſort are taken out of the ground in autumn, and kept in a warm place in winter, they may be planted again in the ſpring, placing them on a hot-bed to forward their ſhooting, and theſe will produce ſtronger plants than thoſe which riſe from ſeeds.

COMMONS and **COMMON-FIELDS.** See Land.

COMPARTMENTS are beds, plats, borders, and walks, laid out according to the form of the ground, and ingenuity of the artiſt, and depend more on a good fancy than any rules. Theſe are diverſified in knots, flower-gardens, or parterres, of which there are great variety, and may be diverſified infinitely, according to the fancy of the deſigners.

Plain compartments are pieces of ground divided into equal ſquares and flower-beds, marked out by the line, of equal length and breadth.

Some perſons allow to theſe ſquares, borders of two feet in breadth, and not more, if the plat of ground be ſmall; but if they be reaſonably large, three feet; and they edge the borders with Box, or upright hardy Thyme, or ſome other aromatic herbs or flowers, for the ſake of the greater neatneſs.

And in order to preſerve the paths and alleys of compartments firm, even, and durable, they lay them with a coat of ſand or gravel, two or three inches thick, keeping them hoed and weeded as often as there ſhould be occaſion.

Theſe compartments were much eſteemed by the French, whoſe gardens were all laid out into ſeveral compartments, ſalons, boſquets, &c. after the manner of architects in buildings; but theſe ſtiff, unnatural gardens are now juſtly exploded, and a much better taſte has of late prevailed in the Engliſh gardens.

COMPOSTS are ſo called of compoſta, or compoſita, *Lat.* compounds, or componere, *Lat.* to compound or mix: and in huſbandry and gardening they ſignify ſeveral ſorts of ſoils or earthy matter mixed together, in order to make a manure for aſſiſting the natural earth in the work of vegetation, by way of amendment or improvement.

Compoſts are various, and ought to be different, according to the different nature or quality of the ſoils which they are deſigned to meliorate: and according as the land is either light, ſandy, looſe, heavy, clayey, or cloddy. A light looſe land requires a compoſt of a heavy nature, as the ſcouring of deep ditches, ponds, &c.

So on the other hand, a land that is heavy, clayey, or cloddy, requires a compoſt of a more ſprightly and fiery nature, that will inſinuate itſelf into the lumpiſh clods; which if they were not thus managed, would very much obſtruct the work of vegetation.

The great uſe of compoſts is for ſuch plants as are preſerved in pots or tubs; or in ſmall beds or borders of flower-gardens; which is what I ſhall here mention, and ſhall treat of thoſe compoſts or dreſſings, which are uſed in gardens and fields, under the articles of Dung and Manure.

As ſome plants delight in a rich light ſoil, others in a poor ſandy ſoil, and ſome in a loamy ſoil; ſo there ſhould be different compoſts prepared, in all thoſe gardens, where a great variety of plants are cultivated: and this is much more neceſſary in countries at a great diſtance from London, than in the neighbourhood of it, becauſe there is ſo great variety of lands, within ten miles round London, which have been ſo long dreſſed and cultivated, that a ſupply of earth fit for all ſorts of plants, may be eaſily procured; but in ſome places which are at a diſtance from large towns, it is very difficult to procure a quantity of earth proper for the choicer ſorts of flowers and plants; therefore the compoſts will require more care, and ſhould be mixed a conſiderable time longer before they are uſed; that they may have the advantage of heat and cold, to meliorate and improve them; and ſhould be frequently turned over, that the parts may be well mixed and incorporated, and the clods well broken and divided.

Almoſt every one who hath written on this ſubject, hath directed the procuring of the upper ſurface of earth from a paſture ground, as one of the principal ingredients, in moſt compoſts for plants, which is certainly a very good one, provided it has time to meliorate before it is uſed; for if this is mixed up haſtily, and put into pots or tubs, before it has had a winter's froſt, and ſummer's heat, to looſen the parts effectually; it will unite and cake together, ſo hard, as to ſtarve the plants that are put into it. For all earth when put into pots or tubs, is much more apt to bind, than when it is in beds; therefore ſhould be in proportion made looſer, according to the nature of the plants for which it is deſigned, than when it is intended for beds or borders. So that if this earth from a paſture, cannot be prepared and mixed at leaſt one year before it is uſed, it will be much better to take the earth of a kitchen-garden which has been well wrought and dunged; but this ſhould be clear from all roots of trees and bad weeds. If this earth is well mixed with the other compoſts ſix months, and often turned over, it will be fitter for pots and tubs, than the other will in twice that time, as I have frequently experienced, ſo can write from knowledge, not from theory. This earth being the principal ingredient in thoſe compoſts deſigned for ſuch plants as require a rich ſoil; the next is to have a quantity of very rotten dung, from old hot-beds; or for thoſe plants which delight in a cool ſoil, a quantity of rotten neats dung is preferable. The proportion of this muſt be according to the quality of the earth; for if that is poor, there ſhould be one third part of dung, but if it be rich, a fourth part or leſs will be ſufficient. Theſe, when well incorporated and the parts divided, will require no other mixture, unleſs the earth is inclinable to bind, in which caſe it will be proper to add ſome ſand or ſea-coal aſhes to it; if ſea-ſand can be eaſily procured, that is the beſt, the next to that is drift-ſand; but that from pits is by no means proper. The proportion of this muſt be according to the nature of the earth, for if that is ſtiff, there muſt be a greater proportion uſed, but this ſhould not exceed a fifth part, unleſs it is very ſtrong, in which caſe it will require more, and a longer time to lie, and muſt be often turned over before it is uſed.

The next compoſt, which is deſigned for plants which do not require ſo good earth, and naturally grow on looſe ſoils, ſhould be half of the before-mentioned earth from a paſture, or that from a kitchen-garden; and if theſe are inclinable to bind, there ſhould be a third part ſand, and the other part rotten tan, which will be of great uſe to keep the parts divided, and let the moiſture paſs off.

The compoſition for moſt of the ſucculent plants, is prepared with the following materials; the earth from a common, where it is light, taken on the ſurface, one half, the other half ſea or drift-ſand, and old lime-rubbiſh ſcreened of equal parts; theſe, well mixed and often turned over, I have found to anſwer better than any other compoſt, for moſt of the very ſucculent plants.

The other ſort of compoſt, which is deſigned for plants that delight in a very looſe, light, rich earth; ſhould be made of light earth taken from a kitchen-garden, which has been well dunged, and thoroughly wrought, like thoſe near London, one half; of rotten tanners bark one third, and the other part mud from the ſcouring of ditches, or from the bottoms of ponds, where the ſoil is fat: but this mud ſhould lie expoſed in ſmall heaps a whole year, and often turned over before it is mixed with the other, and afterward frequently turned and mixed, for eight months or a year before it is uſed.

In all mixtures, where rotten wood may be required, if the rotten tanners bark, which is taken from old hot-beds is uſed, that will anſwer every purpoſe of the other; and wherever ſand is neceſſary in any compoſt, the ſea-ſand ſhould always be preferred to all other, as it abounds with more ſalts; but this ſhould not be uſed freſh, becauſe the ſalts ſhould be expoſed to the air, which will looſen the particles, and thereby render them better adapted for the nutriment of vegetables.

There are ſome who have directed the uſe of rotten leaves of vegetables, as an excellent ingredient in moſt compoſts; but from many years experience, I can affirm, they are of little uſe, and contain the leaſt quantity of vegetable paſture, of any dreſſing which is uſed. Others, who never have had any experience in the culture of plants, have directed different compoſts for almoſt every plant; and theſe compoſts conſiſt of ſuch a variety of ingredients, as greatly to reſemble the preſcriptions of a quack doctor; for no perſon who has been converſant in the buſineſs of gardening, could be guilty of ſuch groſs abſurdities: for it is well known, that a few different compoſts will be ſufficient for all the known plants in the world. But thoſe who pretend to give direction for the culture of plants from theory only, begin at the wrong end, for the true knowledge of gardening or agriculture, muſt be from experience, and is not to be obtained in a garret.

The ſeveral ſorts of dreſſing for land, will be particularly treated under their reſpective titles, and in general they will be mentioned under the article of Dung and Manure.

In making of any compoſt, great care ſhould be had, that the ſeveral parts are properly mixed together, and not to have too much of any one ſort thrown together; therefore, when three or four ſeveral ſorts are to be mixed together, there ſhould be a man or two placed to each ſort, in proportion to the quantity of each; for if two parts of any one ſort are requiſite to be added, there ſhould be two men put to that, and but one to each of the other: and theſe men muſt be careful to ſpread each ſort in ſuch a manner over each other, as that they may be exactly mixed together. Another thing which ſhould be obſerved is, never to lay theſe compoſts in too large heaps, but rather continue them in length, laying them up in a ridge, ſo that the ſun and air may more eaſily penetrate through it: and, as theſe compoſts ſhould (if poſſible) be made a year before they are uſed, that they may enjoy a ſummer's ſun, and winter's froſt, they ſhould be frequently turned over, which will prevent the growth of weeds, and expoſe every part of the heaps equally to the ſun and air, which is of great advantage to all ſorts of compoſts; for the more they are expoſed to the influences of theſe, the better will the earth be prepared for vegetation, which is evinced by the fallowing of land, which, when rightly managed, is equivalent to a dreſſing.

COMPOUND FLOWERS are ſuch as conſiſt of many florets, or ſemiflorets, or both together, which are included in one common empalement, ſo make up what is commonly called one whole flower.

CONE. A cone is a hard, dry, ſeed-veſſel of a conical figure, conſiſting of ſeveral woody parts; and is, for the moſt part ſcaly, adhering cloſely together, and ſeparating when ripe.

CONIFEROUS-TREES are ſuch as bear cones; as, the Cedar of Lebanon, Fir, Pine, &c.

CONIUM. Lin. Gen. Plant. 299. Cicuta. Tourn. Inſt. R. H. 306. tab. 160. Hemlock.

The Characters are,

It is an umbelliferous plant; the general umbel is compoſed of ſeveral ſmall ones termed rays, which ſpread open, the rays or ſmall umbels are alſo ſpread in the like manner. Both theſe have involucrums, compoſed of many ſhort leaves. The petals of the greater umbel are uniform; each flower is compoſed of five unequal heart-ſhaped petals, which turn inward; they have five ſtamina, which are terminated by roundiſh ſummits. The germen, which is ſituated under the flower, ſupports two reflexed ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes a roundiſh channelled fruit, divided into two parts, containing two ſeeds, which are convex and furrowed on one ſide, and plain on the other.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, the flowers having five ſtamina and two ſtyles.

The Species are,

1. Conium (*Maculatum*) ſeminibus ſtriatis. Hort. Cliff. 92. *Conium with ſtriated ſeeds.* Cicuta major. C. B. P. 160. *Greater Hemlock.*
2. Conium (*Tenuifolium*) ſeminibus ſtriatis, foliolis tenuioribus. *Conium with ſtriated ſeeds and narrower leaves.* Cicuta major, foliis tenuioribus. C. B. P. 160. *Greater Hemlock with narrower leaves.*
3. Conium (*Africanum*) ſeminibus aculeatis. Hort. Cliff. 92. *Hemlock with prickly ſeeds.* Caucalis Africana, folio minore, Rutæ. Boerh. Ind. alt. Sp. 63.

The firſt ſort grows naturally on the ſide of banks and roads in many parts of England; this is a biennial plant, which periſhes after it hath ripened ſeeds. It hath a long taper root like a Parſnep, but much ſmaller. The ſtalk is ſmooth, ſpotted with purple, and riſes from four, to upwards of ſix feet high, branching out toward the top into ſeveral ſmaller ſtalks, garniſhed with decompounded leaves, whoſe lobes are cut at the top into three parts; theſe are of a lucid green, and have a diſagreeable ſmell. The ſtalks are terminated by umbels of white flowers, each being compoſed of about ten rays (or ſmall umbels) and have a great number of flowers, which ſpread open, each ſitting upon a diſtinct foot-ſtalk; the ſeeds are ſmall and channelled, and like thoſe of

Aniſeed. It flowers in June, and the ſeeds ripen in autumn.

The ſecond ſort differs from the firſt, in having taller ſtalks, which are not ſo much ſpotted. The leaves are much narrower, and of a paler green; and this difference is conſtant, for I have cultivated it near twenty years in the Chelſea garden, where it has not varied. The ſeeds were ſent me from Germany, where it grows naturally. This is biennial as the former.

The third ſort grows naturally near the Cape of Good Hope, in Africa, from whence the ſeeds were brought to Holland, where the plants have been preſerved in ſome of their curious gardens of plants. The ſeeds of this plant were ſent me by the late Dr. Boerhaave, profeſſor of Botany at Leyden. This plant rarely grows more than nine inches high; the lower leaves are divided ſomewhat like thoſe of the ſmall wild Rue, and are of a grayiſh colour; thoſe upon the ſtalk are much narrower, but of the ſame colour; theſe are terminated by umbels of white flowers, each of the larger umbels being compoſed of three ſmall ones; the involucrum hath three narrow leaves, ſituated under the umbel. This flowers in July, and ripens ſeed in autumn, ſoon after which the plants decay.

The firſt ſort grows wild in moſt parts of England, ſo is ſeldom allowed room in gardens, becauſe it is ſuppoſed to have a poiſonous quality; ſome phyſicians have affirmed that it is ſo to all animals, while others have aſſured us, that it is eaten by the inhabitants of ſome parts of Italy when it is young, and is by them eſteemed a great dainty. Mr. Ray mentions that he has found the gizzard of a thruſh, full of Hemlock ſeeds, with four or five grains of Corn, intermixed with it, which, in the time of harveſt, that bird had neglected for Hemlock, ſo very fond was it of that ſeed which we reckon pernicious. However, it is very certain, that ſcarce any animal will eat the green herb; for it is very common to ſee the graſs, and moſt other weeds eat cloſe where cattle are allowed to feed, and all the plants of Hemlock, which were growing left untouched.

This plant is eſteemed by many phyſicians, as an excellent remedy to diſſolve ſchirrous tumors; and ſome have greatly recommended it for cancers, and moſt of them agree, that it may be preſcribed as a good narcotic.

The ſecond ſort is preſerved in ſome botanic gardens for the ſake of variety. If the ſeeds of this are permitted to ſcatter, the plants will come up in plenty, ſo if they are not rooted out, will become as troubleſome weeds as the firſt ſort.

The third ſort is an humble plant, and being tender, will never become troubleſome; for unleſs the winters are very favourable, this plant will not live in the open air in England. The ſeeds of this ſort ſhould be ſown in pots in autumn ſoon after they are ripe, and placed under a common frame in winter, where they may be expoſed to the open air at all times when the weather is mild, and only covered in bad weather. The plants will come up very early in the ſpring, and muſt then be expoſed to the open air conſtantly when the weather will permit, otherwiſe they will draw up very weak. As theſe plants do not bear tranſplanting well, they ſhould be thinned, and not more than four or five left in each pot; and as the plants have no great beauty, a few of them will be ſufficient to continue the ſort, where a variety of plants are preſerved. The other culture is only to keep them clean from weeds, and in very dry weather to water them.

There is another ſpecies of this genus according to moſt of the botaniſts, which is now ſeparated from it, and placed ſingly, under the title of Æthuſa. This was titled, Cicuta minor petroſelino ſimilis, by Caſpar Bauhin, i. e. *Smaller Hemlock with the appearance of Parſley.* This is a weed which frequently is found in gardens, eſpecially in rich ground, and is generally ſuppoſed to be very poiſonous: ſome perſons who have ignorantly gathered this herb, and uſed it for Parſley, having been poiſoned by it. Therefore it was formerly called Fools Parſley. This may be diſtinguiſhed from Parſley, by the narrowneſs of the ſmall leaves, which are alſo more pointed, and of a darker green. But thoſe who are afraid of being deceived in this, ſhould always uſe the curled Parſley, which is ſo different from this, that it cannot be miſtaken for it.

CONNARUS. Zeylon Sumach.

The Characters are,

It hath a woolly erect empalement of one leaf, cut into five ſegments, which is permanent, and five ſpear-ſhaped erect petals which are equal; it has ten awl-ſhaped ſtamina, which are joined at their baſe, and are alternately long and ſhort, terminated by roundiſh ſummits, and a round germen ſupporting a cylindrical ſtyle, crowned by an obtuſe ſtigma; the empalement afterward becomes an oblong gibbous capſule opening with two valves, having one cell, incloſing one large oval ſeed.

This genus of plants is ranged in the ſecond order of Linnæus's ſixteenth claſs, intitled Monodelphia Decandria, the flower having ten ſtamina, which are joined in one houſe.

We know but one Species of this genus, viz.

Connarus (*Monocarpos*). Flor. Zeyl. 248. *One ſeeded Connarus.* Rhus Zeylanicus trifoliatus, phaſeoli facie, floribus copioſis ſpicatis. Burn. Zeyl. 199. tab. 89.

This plant grows naturally in India; it riſes with a ligneous ſtalk eight or ten feet high, which is hard, rigid, and covered with a black bark, and divides upward into two or three branches, garniſhed with trifoliate leaves, having long foot-ſtalks placed alternate; the lobes are oval, ſmooth, and entire, each having a ſhort petiolus faſtened to the foot-ſtalk; theſe remain green the whole year: the flowers are produced in large panicles at the extremity of the branches, they are ſmall, hairy, and of a greeniſh yellow colour, but are rarely ſucceeded by ſeeds in Europe.

This plant is uſually propagated in the gardens by laying down the young branches, which, if tongued, (in the manner practiſed for Carnations) and duly watered, will put out roots in twelve months, when they may be cut off from the old plants, and each planted in a ſeparate ſmall pot, filled with freſh light earth, plunging them into a moderate hot-bed, to forward their taking new root, obſerving to ſhade them from the ſun every day, and to water them as they may require it: after this the plants ſhould be treated in the ſame way as other exotic plants which are not too tender, placing them in a dry ſtove in winter, and for about three months in the ſummer they may be removed into the open air, in a warm ſheltered ſituation.

The cuttings of this plant will ſometimes take root, if they are planted in pots, plunged into a moderate hot-bed of tanners bark, and cloſely covered with hand-glaſſes, or ſmall bell-glaſſes; but unleſs they are carefully managed they ſeldom ſucceed.

If freſh ſeeds can be procured from abroad, they ſhould be ſown in ſmall pots, plunged into a moderate hot-bed, and when the plants are fit to remove they ſhould be ſeparated, planting each into a ſeparate pot, and plunged into a moderate hot-bed, treating them in the manner as the layers.

CONOCARPODENDRON. See Protea.

CONOCARPUS. Lin. Gen. Plant. 236. Rudbeckia. Houſt. Nov. Gen. 21. Button-tree, vulgò.

The Characters are,

The flowers are collected in a globular head, each ſtanding in a ſcaly empalement. At the bottom is ſituated a large compreſſed germen, crowned by the empalement of the flower, which is ſmall, ſharp-pointed, and divided into five parts at the top. The flower hath five petals; it hath five, or ſometimes ten ſlender ſtamina, which extend beyond the petals, terminated by globular ſummits. The germen is large, compreſſed, and obtuſe, ſupporting a ſingle ſtyle which is longer than the ſtamina, and is crowned by an obtuſe ſtigma. The germen afterward becomes a ſingle ſeed, incloſed in the ſcale of the fruit, which is ſhaped like the cone of Alder.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, from the flower having five ſtamina and one ſtyle.

The Species are,

1. Conocarpus (*Erecta*) foliis lanceolatis erecta. Lin. Sp. 250. *Upright Conocarpus with ſpear-ſhaped leaves.* Rudbeckia erecta longifolia. Houſt. MSS. *Commonly called Button-tree in the Weſt-Indies.*
2. Conocarpus (*Procumbens*) fruteſcens, procumbens, foliis ovatis, craſſis, floribus alaribus & terminalibus. *Shrubby trailing Conocarpus with oval thick leaves, and flowers growing on the ſides, at the ends of the branches.* Rudbeckia maritima procumbens rotundifolia. Houſt. MSS. *Maritime trailing Rudbeckia, with a round leaf.*

The firſt ſort grows plentifully in moſt of the ſandy bays, in all the iſlands of the Weſt-Indies. It riſes with a woody upright ſtem about ſixteen feet high, ſending out many ſide branches, which alſo grow erect; theſe are garniſhed with ſpear-ſhaped leaves, having broad ſhort foot-ſtalks, and are placed alternate on every ſide the branches. The flowers grow upon ſhort branches, which ariſe from the wings of the leaves; theſe have three or four ſmall leaves on their lower part, under the flowers; each of theſe branches are terminated by ſix or eight conical heads of flowers, which have ſome reſemblance to thoſe of Acacia, but each of theſe come out of a ſcaly covering; the flowers are ſmall, of a reddiſh colour, having five ſlender ſtamina, and one ſtyle, which ſtand out farther than the petal. The flowers are ſucceeded by ſingle ſeeds, which are included in the ſcales of the conical fruit.

The ſecond ſort hath ſhort crooked branches, which divide and ſpread out on every ſide upon the ground; theſe are covered with a grayiſh bark, and their upper parts are garniſhed with oval thick leaves, a little larger than thoſe of the Dwarf Box; they have very ſhort foot-ſtalks, and are placed on every ſide the branches without order. The flowers are collected in ſmall round heads, which come out ſingle from the ſide of the branches, and in looſe ſpikes at the end; theſe are ſmall, and of an herbaceous colour; the ſcales are rough, and the cones are of a looſer texture than thoſe of the former ſort.

This was diſcovered by the late Dr. William Houſtoun, growing plentifully in the marſhy grounds near the ſea, at the Havannah, from whence he ſent the ſeeds to England, in 1730.

Both theſe ſorts are preſerved in ſome curious gardens for the ſake of variety, but they are plants of no great beauty: they are propagated from ſeeds, which muſt be obtained from the places of their natural growth, for they never produce any good ſeeds in Europe: theſe ſeeds, if they are freſh, will come up very ſoon, if they are ſown upon a good hot-bed; and if the plants are potted, and preſerved in the bark-ſtove, they will make great progreſs; but they are too tender to live in this country, unleſs they are conſtantly kept in the ſtove, and treated in the ſame manner with other exotic plants; obſerving, as they are natives of ſwamps, to ſupply them often with water; but in winter they muſt have it very ſparingly. The plants are Evergreen, caſting off their old leaves when the new come out.

CONSOLIDA MAJOR. See Symphytum.

CONSOLIDA MEDIA. See Bugula.

CONSOLIDA MINIMA. See Bellis.

CONSOLIDA REGALIS. See Delphinium.

CONVALLARIA. Lin. Gen. Plant. 383. Lilium Convallium. Tourn. Inſt. R. H. 77. tab. 14. *Lily of the valley.* To this genus Dr, Linnæus has joined the Polygonatum of Tournefort, or Solomon's Seal.

The Characters are,

The flower hath one petal, which is bell-ſhaped, and divided at the brim into ſix obtuſe ſegments which ſpread open and are reflexed. It hath no empalement. It hath ſix ſtamina, which are inſerted into the petal, but are ſhorter, terminated by oblong ſummits, which are erect. In the center is ſituated a globular germen, ſupporting a ſlender ſtyle, which is longer than the ſtamina, crowned by a three cornered obtuſe ſtigma. The germen afterward becomes a globular berry, with three cells, containing one roundiſh ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, the flower having ſix ſtamina and one ſtyle.

The Species are,

1. Convallaria (*Majalis*) ſcapo nudo. Flor. Lapp. 113. *Convallaria with a naked ſtalk.* Lilium convallium album. C. B. P. 304. *White Lily of the Valley.* There is a variety of this with reddiſh flowers, which is preſerved in gardens, titled by Caſpar Bauhin Lilium Convallium flore rubente. Pin. 304.
2. Convallaria (*Latifolia*) ſcapo nudo, foliis latioribus. *Convallaria with a naked ſtalk and broader leaves.* Lilium Convallium latifolium. C. B. P. 136. *Broad-leaved Lily of the Valley.* There is alſo a variety of this with double variegated flowers which is preſerved in gardens. This Tournefort titles Lilium Convallium latifolium, flore pleno variegato. Inſt. R. H. 77. *Broad-leaved Lily of the Valley, with a large variegated flower.*
3. Convallaria (*Multiflora*) foliis alternis, amplexicaulibus caule tereti axillaribus pedunculis multifloris. *Convallaria with leaves placed alternate, embracing the taper ſtalk, whoſe foot-ſtalks have many flowers.* Polygonatum latifolium vulgare. C. B. P. 305. *Common broad-leaved Solomon's Seal.*
4. Convallaria (*Odorato*) foliis alternis, ſemiamplexicaulibus, floribus majoribus axillaribus. *Convallaria with alternate leaves which half embrace the ſtalks, and larger ſweet-ſcented flowers.* Polygonatum latifolium, flore majore odoro. C. B. P. 303.
5. Convallaria (*Polygonatum*) foliis alternis amplexicaulibus, caule ancipti, pedunculis axillaribus ſubunifloris. Lin. Mat. Med. 168. *Convallaria with alternate leaves embracing the ſtalks, and foot-ſtalks having one flower.* Polygonatum floribus ex ſingula tribus pedunculis. C. B. 3. p. 530. *Common Solomon's Seal.*
6. Convallaria (*Stellata*) foliis amplexicaulibus plurimis. Lin. Sp. 452. *Convallaria with many leaves embracing the ſtalks.* Polygonatum Canadenſe ſpicatum fertile. Cornut. Canad. 33.
7. Convallaria (*Verticillata*) foliis verticillatis. Flor. Lapp. 114. *Convallaria with leaves growing in whorls.* Polygonatum anguſtifolium, non ramoſum. C. B. P. 303.
8. Convallaria (*Racemoſa*) foliis ſeſſilibus, racemo terminali compoſito. Lin. Sp. Plant. 452. *Convallaria with leaves ſitting cloſe to the ſtalks, which are terminated by compound ſpikes of flowers.* Polygonatum Virginianum erectum, ſpicatum, flore ſtellato ſterili. Mor. Hiſt. 3. 537.
9. Convallaria (*Bifolia*) foliis cordatis. Flor. Lapp. 113. *Convallaria with heart-ſhaped leaves.* This is the Smilax unifolio humillima. Tourn. Inſt. App. 564. *Loweſt Smilax with a ſingle leaf; and the* Lilium Convallium minus. C. B. P. 304. *The leaſt Lily of the Valley.*

The firſt ſort grows naturally in great plenty in the woods near Woburn, in Bedfordſhire, from whence the markets in London are generally ſupplied with the flowers. It is alſo cultivated in gardens for the ſweetneſs of the flowers, and formerly it grew in great plenty on Hampſtead-heath, but of late years it has been ſeldom found there; for ſince all the trees have been deſtroyed, the plants have not flowered there as formerly, nor have the roots increaſed.

This hath a ſlender fibrous root, which creeps under the ſurface of the ground, and thereby propagates in great plenty. The leaves come up by pairs; their foot-ſtalks, which are about three inches long, are wrapped together in one cover, and at the top divide into two parts, each ſuſtaining a ſingle leaf, one of which riſes a little above the other; theſe leaves are from four to five inches long, and near an inch and a half broad in the middle, leſſening gradually to both ends; they have many longitudinal veins, running parallel to the midrib, which is not ſituated exactly in the middle, but diverges to one ſide; the foot-ſtalks of the flowers ariſe immediately from the root, on one ſide the leaves; theſe are naked, about five inches long, adorned toward their upper parts with pendulous white flowers, ranged on one ſide the ſtalk, which decline to one ſide; each flower ſtands upon a ſhort ſeparate foot-ſtalk, which are bending and crooked. The flowers are of the ſhort bell-ſhaped kind, their brims being reflexed, which are ſlightly cut into ſix parts; they have ſix ſtamina, which are inſerted in the petal of the flower, and are ſhorter than the tube, and a ſingle ſtyle ariſing from the germen, which is triangular, crowned by a three-cornered ſtigma; the germen afterward becomes a globular berry, of a red colour when ripe, incloſing three roundiſh ſeeds. It flowers in May, from whence it has been titled May Lily. The ſeeds ripen in autumn. The flowers of this ſort are uſed in medicine; they are eſteemed cephalic and cordial, ſo are recommended for palſies, epilepſies, and ſpaſms; there is prepared a conſerve, and a compound diſtilled water of the flowers. This compound water is by the Germans titled aqua aurea, or *golden water*, becauſe of its excellent virtues.

There is another variety of this mentioned with narrow leaves, which I ſuppoſe may ariſe from the ſoil, or ſituation, for the roots which I have taken up in places where they have naturally narrow leaves, when planted in the garden, have produced leaves as broad as the common ſort; but the ſort with red flowers has conſtantly continued the ſame above forty years, without any variation. The flowers of this are ſmaller, the ſtalks are redder, and the leaves of a darker green than thoſe of the common ſort; but as I have not propagated this ſort by ſeeds, I cannot be ſure if it is a diſtinct ſpecies, or only a ſeminal variety.

The ſecond ſort I received from the Alps, where it naturally grows; this has retained its difference in the garden, where it grew in the ſame ſoil and ſituation with the common ſort, ſo I make no doubt of its being a diſtinct ſpecies. The other with a double variegated flower is ſuppoſed to be only a variety of this, therefore I have not enumerated it as a different ſort, but the flowers are much larger, and beautifully variegated with purple and white. I received a plant of this ſort from the royal garden at Paris, which has flowered ſeveral years in the Chelſea garden, but the roots do not increaſe ſo much as the common ſort.

Theſe plants require a looſe ſandy ſoil, and a ſhady ſituation; they are propagated by parting of their roots, which multiply in great plenty. The beſt time to tranſplant and part the roots, is in autumn. They ſhould be planted near a foot aſunder, that their roots may have room to ſpread, for if they agree with the ſoil and ſituation, they will meet and fill the ground in one year. If theſe roots are planted in a rich ſoil, they will ſpread and multiply greatly, but will not be ſo productive of flowers.

The only culture which theſe plants require, is to keep them clean from weeds, and to tranſplant and ſeparate the roots every third or fourth year, otherwiſe they will be ſo greatly matted together, as not to have proper nouriſhment, ſo the flowers will be ſmall, and few in number.

The third ſort is a native of the Alps and Appennines; the ſtalks of this (when growing in good ground) generally riſe three feet high; they are taper, and garniſhed with oblong oval leaves placed alternate, embracing the ſtalks with their baſe; they have ſeveral longitudinal veins, reſembling the leaves of white Hellebore: the foot-ſtalks of the flowers are produced from the wings of the leaves, which ſupport four or five flowers on each; theſe flowers are larger than thoſe of the common ſort, but their tubes are more contracted, and are ſucceeded by pretty large berries, which when ripe turn of a bluiſh colour; it flowers in May and June, and the ſeeds ripen in autumn.

The fourth ſort is the broad-leaved Solomon's Seal, which is ſaid to grow naturally in England, but I doubt ours is different from that mentioned by Caſpar Bauhin under that title; for in two places where I have found it growing, the ſtalks were much ſhorter, the leaves were broader, and their borders turned inward, and this difference continues in the garden where it grows in the ſame ſoil and ſituation with the common ſort.

The fifth ſort is the common Solomon's Seal; this hath a fleſhy white root, as large as a man's finger, which multiplies in the ground, and is full of knots, from whence it had the name of Polygonatum, or many knees. In the ſpring ariſe ſeveral taper ſtalks, which grow near two feet high, adorned with oblong oval leaves, placed alternate, having many longitudinal veins running parallel to the middle, and embrace the ſtalk with their baſe; theſe are ranged on one ſide of the ſtalk, and on the oppoſite ſide come out the foot-ſtalks of the flowers, which are about an inch long, dividing at the top into three or four ſmaller, each ſuſtaining a ſingle tubulous flower, cut into ſix parts at the brim, where it is green, the lower part of the tube being white; they have each ſix ſlender ſtamina, ſurrounding a ſingle ſtyle, which ariſes from the germen, and is crowned by a blunt ſtigma; the germen afterward becomes a round berry, about the ſize of Ivy berries, each incloſing three ſeeds. This flowers in May, and the ſeeds ripen in autumn, and then the ſtalks decay.

The ſixth ſort riſes with an upright ſtalk about two feet high, garniſhed with long narrow leaves, which ſtand in whorls round the ſtalk; there are generally five of theſe placed at each joint, which are four inches long, and half an inch broad, ſmooth, and of a light green. The flowers come out from the ſame joints, ſtanding upon ſhort foot-ſtalks, each ſupporting five or ſix flowers, which are ſmaller, and have much ſhorter tubes than either of the former ſorts; they are of a dirty white, tipped with green, and ſlightly cut into ſix parts at the top. It grows naturally in the northern parts of Europe.

The ſeventh ſort grows naturally in moſt parts of North America; I have received plants of this from New England, Philadelphia, and ſeveral other places. This riſes with an upright ſtalk near two feet high, garniſhed with oblong leaves, ending in ſharp points; they are near five inches long, and two and a half broad, having three large longitudinal veins, with ſeveral ſmaller between, which join at both ends. The leaves are alternate, ſtanding cloſe to the ſtalks, and are of a light green on their upper ſide, but are paler on their under. The flowers are produced in branching ſpikes at the extremity of the ſtalks, each being compoſed of ſeveral ſmall looſe ſpikes of ſtar-like flowers, of a pale yellow, which fall away without producing any ſeed. This flowers the latter end of May, or the beginning of June, and the ſtalks decay in autumn; but the root is perennial, and propagates by offſets.

The eighth ſort is a native of the ſame countries as the laſt mentioned; this ſends up ſtalks two feet high, garniſhed with many oblong leaves embracing the ſtalks with their baſe. The flowers are produced in ſingle ſpikes at the top of the ſtalks, which are in ſhape and colour like thoſe of the ſeventh; but theſe are ſucceeded by ſmall red berries, about the ſize of thoſe of the Lily of the Valley. This ſort flowers the beginning of June, and the berries ripen in autumn.

All the ſorts of Solomon's Seal are very hardy plants; they delight in a light ſoil and a ſhady ſituation, ſo are very proper to plant in wilderneſs quarters under tall trees, where if they are not crowded by lower ſhrubs, they will thrive and multiply exceedingly, and during the ſummer ſeaſon will make an agreeable variety, the whole appearance of the plants being very ſingular.

They all multiply very faſt by their creeping roots, eſpecially when they are planted in a proper ſoil and ſituation. The beſt time to tranſplant and part the roots is in autumn, ſoon after their ſtalks decay; thoſe which are removed at that ſeaſon, will grow much ſtronger than thoſe which are planted in the ſpring, which is the reaſon of my preferring that ſeaſon; but they may be ſafely tranſplanted any time after the ſtalks decay, till the roots begin to ſhoot in the ſpring. As theſe roots greatly increaſe, they ſhould be planted at a wide diſtance from each other, that they may have room to ſpread; for they ſhould not be removed oftener than every third or fourth year, where they are expected to grow ſtrong, and produce a good number of ſtalks, in which their beauty conſiſts. The only culture theſe plants require, is to dig the ground between them every ſpring, and keep them clean from weeds.

The roots of the fifth ſort are uſed in medicine, and are greatly recommended for their efficacy in all manner of contuſions. The diſtilled water of the plant clears the face and beautifies the complexion: a decoction of it cures the itch, and ſuch like cutaneous diſtempers.

CONVOLVULUS. Lin. Gen. Plant. 198. Tourn. Inſt. R. H. 82. tab. 77. Bindweed. It is ſo titled from convolvendo, *Lat.* rolling round, or twining about.

The Characters are,

It hath a permanent empalement of one leaf, which is divided into five parts at the top; the flower hath one large bell-ſhaped petal, which ſpreads open. It hath five ſhort ſtamina, terminated by oval compreſſed ſummits, and a roundiſh germen, ſupporting a ſlender ſtyle, crowned by two broad oblong ſtigmas. The empalement afterward becomes a roundiſh capſule, with one, two, or three valves, containing ſeveral ſeeds which are convex on their outſide, but on the inſide angular.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Convolvulus (*Arvenſis*) foliis ſagittatis utrinque acutis, pedunculis unifloris. Flor. Suec. 173. *Bindweed with arrow-ſhaped leaves pointed on both ſides, and a ſingle flower on each foot-ſtalk.* Convolvulus minor arvenſis. C. B. P. 294. *Smaller Field Bindweed, commonly called Gravel Bindweed.*
2. Convolvulus (*Sepium*) foliis ſagittatis poſticè truncatis, pedunculis tetragonis unifloris. Prod. Leyd. 427. *Bindweed with arrow-ſhaped leaves, which are torn behind, and a ſingle flower on each foot-ſtalk.* Convolvulus major albus. C. B. P. *Larger white Bindweed, called Bearbind.*
3. Convolvulus (*Scammonia*) foliis ſagittatis poſticè truncatis, pedunculis teretibus ſubtrifloris. Prod. Leyd. 427. *Bindweed with arrow-ſhaped leaves torn behind, and two flowers on each foot-ſtalk.* Convolvulus Syriacus & Scammonia Syriaca. Mor. Hiſt. 2. p. 12. *Syrian Bindweed and Syrian Scammony.*
4. Convolvulus (*Purpureus*) foliis cordatis indiviſis fructibus cernuis pedicellis incraſſatis. Lin. Sp. 219. *Bindweed with heart-ſhaped undivided leaves, nodding fruit, and ſwelling foot-ſtalks.* Convolvulus purpureus, folio ſubrotundo. C. B. P. 295. *Purple Bindweed with a roundiſh leaf, commonly called* Convolvulus major, or *Greater Bindweed.*
5. Convolvulus (*Indicus*) foliis cordatis, acuminatis, pedunculis trifloris. *Bindweed with heart-ſhaped pointed leaves, and three flowers on each foot-ſtalk.* Convolvulus major, folio ſubrotundo, flore amplo purpureo. Sloan. Cat. Jam. 55. *Greater Bindweed with a roundiſh leaf, and a large purple flower.*
6. Convolvulus (*Nil*) foliis cordatis trilobis villoſis, calycibus lævibus, capſulis hirſutis, pedunculis bifloris. *Bindweed with heart-ſhaped leaves, having three lobes, which are hairy, ſmooth flower-cups, hairy ſeed-veſſels, and two flowers on each foot-ſtalk.* Convolvulus cæruleus hederaceo anguloſo folio. C. B. P. 295. *Blue Bindweed with an angular Ivy leaf.*
7. Convolvulus (*Batatas*) foliis cordatis haſtatis quinquenerviis, caule repente hiſpido tubifero. Lin. Sp. Plant. 154. *Bindweed with ſpear heart-ſhaped leaves, five nerves, and a creeping ſtinging ſtalk bearing tubers.* Convolvulus radice tuberoſâ eſculenſâ minore purpurea. Sloan. Cat. Jam. 54. *Bindweed with a ſmall, purple, tuberous, eſculent root, commonly called Spaniſh Potatoes.*
8. Convolvulus (*Palmatis*) foliis palmatis, lobis ſeptem-ſinuatis acutis, pedunculis unifloris, calycibus maximis patentibus. *Bindweed with palmated leaves, with ſeven ſinuated pointed lobes, a ſingle flower on each foot-ſtalk, and a large ſpreading empalement.* Convolvulus pentaphyllos, folio glabro dentato, viticulis hirſutis. Plum. Cat.
9. Convolvulus (*Ariſtolochiofolius*) folio haſtato lanceotis, auriculis rotundatis, pedunculis multifloris. *Bindweed with ſpear-pointed leaves, having rounded ears, and many flowers on each foot-ſtalk.* Convolvulus Americanus, Ariſtolochiæ folio longiore, floribus plurimis ex uno pediculo inſidentibus. Houſt. MSS.
10. Convolvulus (*Hirtus*) foliis cordatis ſubhaſtatiſque villoſis, caule petioliſque piloſis, pedunculis multifloris. Lin. Sp. Plant. 159. *Bindweed with heart-ſhaped leaves, ſomewhat ſpear-pointed and downy, with hairy ſtalks and foot-ſtalks, having many flowers.* Convolvulus Americanus Polyanthos, Althææ folio villoſo. Houſt. MSS.
11. Convolvulus (*Glabrus*) foliis ovato oblongis, glabris pedunculis unifloris, calycibus decempartitis. *Bindweed with oval, oblong, ſmooth leaves, and foot-ſtalks having a ſingle flower, whoſe empalement is cut into ten parts.* Convolvulus foliis oblongis, glabris floribus amplis purpureis. Houſt. MSS.
12. Convolvulus (*Pentaphyllos*) hirſutiſſimus, foliis quinquelobatis, pedunculis longiſſimis bifloris. *Very hairy Bindweed, with leaves having five lobes, and very long foot-ſtalks, with two flowers.* Convolvulus pentaphyllos hirſutis. Plum. Cat.
13. Convolvulus (*Fruteſcens*) caule fruticoſo, glabro, foliis quinque lobis, pedunculis geniculatis unifloris, capſulis maximis. *Bindweed with a ſhrubby ſmooth ſtalk, leaves having five lobes, many jointed foot-ſtalks with one flower, and very large ſeed-veſſels.* Convolvulus pentaphyllos, flore & fructu purpureis maximis. Plum. Cat.
14. Convolvulus (*Braſilienſis*) foliis emarginatis, baſi biglanduloſis, pedunculis trifloris. Lin. Sp. Plant. 159. *Bindweed with indented leaves, having two glands and foot-ſtalks, with three flowers.* Convolvulus marinus Catharticus, folio rotundo, flore purpureo. Plum. Pl. Amer. 89. tab. 104.
15. Convolvulus (*Multiflorus*) foliis cordatis, glabris, pedunculis multifloris, ſemine villoſo ferrugineo. *Bindweed with ſmooth heart-ſhaped leaves, foot-ſtalks having many flowers, and ſeeds covered with an iron-coloured down.* Convolvulus Americanus vulgaris folio, capſulis triquetris numeroſis, ex uno puncto, longis petiolis propendentibus, ſemine lanugine ferrugineâ villoſa. Pluk. Phyt. tab. 167. f. 1.
16. Convolvulus (*Canarienſis*) foliis cordatis pubeſcentibus, caule perenni, villoſo, pedunculis multifloris. Lin. Sp. Plant. 155. *Bindweed with ſoft, woolly, heart-ſhaped leaves, a hairy perennial ſtalk, and foot-ſtalks having many flowers.* Convolvulus Canarienſis ſempervirens, foliis mollibus & incanis. Hort. Amſt. 2. p. 101.
17. Convolvulus (*Hederaceus*) foliis triangularibus acutis, floribus plurimis ſeſſilibus patulis, calycibus acutis multifidis. *Bindweed with ſharp-pointed triangular leaves, many ſpreading flowers ſet cloſe to the ſtalk, and acute empalements ending in many points.* Convolvulus folio hederaceo, anguloſo, lanuginoſo, flore magno, cæruleo, patulo. Sloan. Cat. Jam. 56.
18. Convolvulus (*Roſeus*) foliis cordatis, acuminatis pedunculis bifloris. *Bindweed with heart-ſhaped pointed leaves, and foot-ſtalks having two flowers.* Convolvulus Americanus hirſutus, folio acuminato, flore amplo roſeo. Houſt. MSS.
19. Convolvulus (*Repens*) foliis ſagittatis poſticè obtuſis, caule repente, pedunculis unifloris. Lin. Sp. Plant. 158. *Bindweed with narrow-pointed leaves, which are obtuſe at the foot-ſtalk, a creeping ſtalk, and one*

flower on each foot-ſtalk. Convolvulus marinus catharticus, foliis Acetoſæ, flore niveo. Plum. Pl. Am. 89. tab. 105.

20. Convolvulus (*Betonicifolius*) foliis cordato ſagitatis, pedunculis unifloris. *Bindweed with heart-ſhaped arrow-pointed leaves, and foot-ſtalks having a ſingle flower.* Convolvulus exoticus, Betonicæ folio, flore magno albo fundo purpureo. Cat. Hort. R. Par.

21. Convolvulus (*Siculus*) foliis cordato ovatis, pedunculis unifloris, bracteis lanceolatis, flore ſeſſile. Hort. Cliff. 68. *Bindweed with oval heart-ſhaped leaves, foot-ſtalks having one flower, ſpear-ſhaped bracteæ, and the flower ſitting cloſe to the ſtalk.* Convolvulus ſiculus minor, flore parvo auriculato. Bocc. Pl. Sic. 89.

22. Convolvulus (*Elegantiſſimus*) foliis palmatis ſericeis, pedunculis bifloris, calycibus acutis. *Bindweed with ſilky palmated leaves, foot-ſtalks having two flowers, and ſharp-pointed empalements.* Convolvulus argentibus, elegantiſſimus, foliis tenuiter inciſis. Tourn. Inſt. R. H. 85.

23. Convolvulus (*Altheoides*) foliis cordatis inciſis & incanis, pedunculis bifloris, calycibus obtuſis. *Bindweed with hoary heart-ſhaped leaves, which are jagged, foot-ſtalks having two flowers, and obtuſe empalements.* Convolvulus argenteus folio althææ. C. B. P. 295.

24. Convolvulus (*Tricolor*) foliis lanceolato-ovatis glabris, caule declinato, floribus ſolitariis. Vir. Cliff. 68. *Bindweed with oval ſpear-ſhaped leaves, a declining ſtalk, with one flower on each foot-ſtalk.* Convolvulus Luſitanicus flore Cyaneo Broſ; *commonly called Convolvulus minor.*

25. Convolvulus (*Cantabrica*) foliis linearibus acutis caule ramoſo ſubdichotomo, calycibus piloſis. Lin. Sp. 225. *Bindweed with narrow ſpear-ſhaped leaves, a branching ſtalk, and hairy empalements.* Convolvulus linariæ folio aſſurgens. Tourn. Inſt. R. H. 83.

26. Convolvulus (*Lineatus*) foliis lanceolatis, ſericeis, lineatis petiolatis pedunculis bifloris, calycibus ſereceis ſubfoliaceis. Lin. Sp. 224. *Bindweed with ſilky ſpear-ſhaped leaves, having foot-ſtalks, with two flowers on each foot-ſtalk, having ſilky empalements.* Convolvulus minor, argenteus, repens, acaulis ferme. H. R. Par.

27. Convolvulus (*Cneorum*) foliis lanceolatis tomentoſis, floribus capitatis, calycibus hirſutis caule erectiuſculo. Lin. Sp. 224. *Bindweed with ſpear-ſhaped woolly leaves, foot-ſtalks and flowers growing in heads, terminating the ſtalks, which are erect.* Convolvulus argenteus umbellatus, erectis. Tourn. Inſt. R. H. 84.

28. Convolvulus (*Linarifolius*) foliis lineari lanceolatis, acutis caule ramoſo, recto, pedunculis unifloris. Hort. Cliff. 68. *Bindweed with narrow ſpear-ſhaped leaves, which are pointed, upright branching ſtalks, and foot-ſtalks with one flower.* Convolvulus ramoſus incanus, foliis piloſellæ. C. B. P. 295.

29. Convolvulus (*Soldanella*) foliis reniformibus, pedunculis unifloris. Hort. Cliff. 67. *Bindweed with kidney-ſhaped leaves, and one flower on each foot-ſtalk.* Soldanella maritima minor. C. B. P. 295. *Leſſer Sea Bindweed.*

30. Convolvulus (*Turpethum*) foliis cordatis, angulatis, caule membranaceo, quadrangulari, pedunculis multifloris. Flor. Zeyl. 72. *Bindweed with angular heart-ſhaped leaves, a quadrangular membranaceous ſtalk, and foot-ſtalks having many flowers.* Convolvulus Zeylanicus, alatus, maximis, foliis Ibiſci nonnihil ſimilibus anguloſis. Herm. Lud. 177. tab. 178. *Turbith of the ſhops.*

31. Convolvulus (*Jalapa*) foliis variis, pedunculis unifloris, radice tuberoſâ. *Bindweed with variable leaves, foot-ſtalks with ſingle flowers, and a tuberous root.* Convolvulus radice tuberoſâ Catharticâ. Houſt. MSS. *The true Jalap.*

The firſt ſort is very common upon dry banks, and in gravelly grounds, in moſt parts of England, and is generally a ſign of gravel lying under the ſurface. The roots of this ſhoot very deep into the ground, from whence ſome country people call it Devils Guts.

From the root ariſes many weak ſtalks, which trail on the ground, and faſten themſelves about the neighbouring plants; theſe are garniſhed with triangular arrow-pointed leaves. The flowers are produced from the ſide of the branches, having long foot-ſtalks, each ſuſtaining a ſingle flower, which is ſometimes white, at other times red, and frequently is variegated. This is a troubleſome weed in gardens, ſo ſhould be conſtantly rooted out.

The ſecond ſort is alſo a troubleſome weed in gardens, when the roots are intermixed with thoſe of trees and ſhrubs, or under hedges, where the plants cannot be eaſily deſtroyed; but in an open clear ſpot of ground, where the plants are carefully hoed down for three or four months, they may be effectually deſtroyed; for when the ſtalks are broken or cut, a milky juice flows out, and thereby the roots are ſoon exhauſted and decay. The roots of this ſort are pretty thick, extend far on every ſide, and are white. The ſtalks riſe ten or twelve feet high, twining themſelves about trees or hedges, and are garniſhed with large arrow-pointed leaves, which are torn at their baſe. The flowers come out from the ſide of the branches upon long foot-ſtalks, each ſuſtaining one large white flower, which are ſucceeded by roundiſh ſeed-veſſels, having three cells filled with ſeeds, which are convex on one ſide and plain on the other. It flowers in June, and the ſeeds ripen in autumn, ſoon after which the ſtalks decay to the root; but as every ſmall piece of the root will grow, it renders this a troubleſome weed to deſtroy.

The third ſort grows naturally in Syria, where the roots of the plants are wounded, and ſhells placed under the wounds to receive the milky juice which flows out, which is inſpiſſated, and afterward put up and exported: this is what is called Scammony in the ſhops; it is a very hardy plant, and will thrive very well in the open air in England, provided it is on a dry ſoil. The roots of this are thick, run deep into the ground, and are covered with a dark bark. The branches extend themſelves on every ſide to the diſtance of four or five feet; theſe are ſlender, and trail on the ground, if they are not ſupported, and are garniſhed with narrow arrow-pointed leaves. The flowers are of a pale yellow, and come out from the ſide of the branches, two ſitting upon each long foot-ſtalk; theſe are ſucceeded by roundiſh ſeed-veſſels, having three cells, filled with ſeeds ſhaped like thoſe of the former ſort, but ſmaller. It flowers in June and July, and the ſeeds ripen in autumn. If the ſeeds of this ſort are ſown in the ſpring, on a border of light earth, the plants will come up, and require no other culture but to keep them clean from weeds, and thin the plants where they grow too cloſe; for as the branches extend pretty far, the plants ſhould not be nearer than three feet aſunder. The ſtalks decay in autumn, but the roots will abide many years.

The fourth ſort is an annual plant, which grows naturally in Aſia and America, but has been long cultivated for ornament in the Engliſh gardens, and is generally known by the title of Convolvulus major. Of this there are three or four laſting varieties; the moſt common hath a purple flower; but there is one with a white, another with a red, and one with a whitiſh blue flower, which hath white ſeeds. All theſe varieties I have cultivated many years, without obſerving either of them change. If the ſeeds of theſe ſorts are ſown in the ſpring, upon a warm border where the plants are deſigned to remain, they will require no other culture but to keep them clean from weeds; and place ſome tall ſtakes down by them, for their ſtalks to twine about, otherwiſe they will ſpread on the ground, and make a bad appearance. Theſe plants, if they are properly ſupported, will riſe ten or twelve feet high; they flower in June, July, and Auguſt, and will continue till the froſt kills them. Their ſeeds ripen in autumn.

The fifth ſort grows naturally in Jamaica, from whence the late Dr. Houſtoun ſent me the ſeeds; this ſends out long branches, which twiſt about the trees, and riſe to a great height; the leaves are ſmooth, heart-ſhaped, ending in long points, and the ears at the baſe are large and rounded, ſtanding upon long ſlender foot-ſtalks. The flowers come out on the oppoſite ſide of the ſtalks, upon long foot-ſtalks, each ſuſtaining three flowers, with longer tubes than thoſe of the former, and are of a deeper purple colour; this flowers from the latter end of June till the froſt deſtroys it. As this is not ſo hardy as the former, the ſeeds ſhould be ſown upon a hot-bed in the ſpring, to bring the plants forward; and toward the end of May, they ſhould be planted out in warm borders, and treated in the ſame manner as the former ſort.

The ſixth ſort grows naturally in Africa and America; this is an annual plant, which riſes with a twining ſtalk eight or ten feet high, garniſhed with heart-ſhaped leaves, divided into three lobes, which end in ſharp points; theſe are woolly, and ſtand upon long foot-ſtalks; the flowers come out on long foot-ſtalks, each ſuſtaining two flowers of a very deep blue colour, from whence it has been titled Anil or Indigo. This is one of the moſt beautiful flowers of this genus, and is undoubtedly a diſtinct ſpecies; though ſome have ſuppoſed it to be only a variety of the fourth ſort, for I have cultivated it many years, and have never found it alter; the leaves of this having three deeply divided lobes, and thoſe of the fourth ſort being entire, is ſufficient to determine the ſpecific difference; this ſort is annual, and muſt be propagated in the ſame manner as the fifth. It flowers all the latter part of ſummer, and, in good ſeaſons, the ſeeds ripen well in the open air.

The ſeventh ſort is that whoſe roots are eaten, and is generally titled Spaniſh Potatoe; theſe roots are annually imported from Spain and Portugal, where they are greatly cultivated for the table, but they are too tender to thrive well in the open air in England; they are cultivated by the roots in the ſame way as the common Potatoe, but require much more room; for theſe ſend out many trailing ſtalks, which extend four or five feet every way, and at their joints ſend out roots, which, in warm countries, grow to be large tubers, ſo that from a ſingle root planted, forty or fifty large roots are produced. This plant is ſometimes propagated by way of curioſity in England, but the roots ſhould be planted on a hot-bed in the ſpring; and if the plants are kept covered in bad weather with glaſſes, they will produce flowers, and many ſmall roots will be produced from the joints; but if they are expoſed to the open air, they ſeldom make much progreſs.

The eighth ſort grows naturally at La Vera Cruz in New Spain, from whence the ſeeds were ſent me by the late Dr. Houſtoun. This riſes with a ſtrong winding ſtalk to the height of twenty feet, dividing into ſeveral ſmaller, which faſten themſelves about any of the neighbouring trees and ſhrubs; theſe are garniſhed with leaves in ſhape of a hand, having ſeven lobes, which are ſpear-ſhaped, and deeply cut on their borders, ending in ſharp points. The flowers are ſingle on each foot-ſtalk, which are very long. The empalement of the flower is large, ſpreading open, and is divided deeply into five parts. The flowers are large, of a purple colour, and are ſucceeded by large roundiſh ſeed-veſſels, having three cells, in each of theſe is lodged a ſingle ſeed.

This plant is tender, ſo the ſeeds ſhould be ſown on a hot-bed in the ſpring; and when the plants are fit to remove, they muſt be tranſplanted each into a ſeparate pot filled with light earth, and plunged into a moderate hot-bed, obſerving to ſhade them from the ſun till they have taken new root; then they ſhould have a large ſhare of air admitted to them every day, to prevent their drawing weak, and alſo ſhould have moderate waterings three or four times a week. When the plants are grown too tall to remain in the hot-bed, they muſt be ſhifted into larger pots, and placed in the bark-ſtove, where, if they are allowed room, they will riſe to a great height, and produce flowers, but it rarely produces ſeeds in England.

The ninth ſort is an annual plant. The ſeeds of this were ſent me from Carthagena in New Spain, where the plant grows naturally. This riſes with a twining ſlender ſtalk ten feet high, which is garniſhed with arrow-pointed leaves, whoſe ears at the baſe are rounded. The flowers are produced in ſmall cluſters, ſtanding on long foot-ſtalks; theſe are yellow, and are ſucceeded by three-cornered ſeed-veſſels, having three cells, in each of theſe are lodged two ſeeds.

This plant is annual, and too tender to thrive in the open air in England; ſo the ſeeds ſhould be ſown on a hot-bed in the ſpring, and the plants may be afterward treated in the ſame way as the eighth ſort, with which management they will flower and produce ripe ſeeds.

The ſeeds of the tenth ſort were ſent me from Jamaica by the late Dr. Houſtoun, who found the plants growing naturally there in great plenty. This is an annual plant, riſing with ſlender, ſtiff, twining ſtalks, eight or nine feet high, garniſhed with heart-ſhaped leaves, which are downy. The flowers ſtand many together at the end of ſtrong foot-ſtalks; theſe are purple, and are ſucceeded by roundiſh ſeed-veſſels, with three cells, containing ſeveral ſmall ſeeds.

This ſort requires the ſame treatment as the eighth, being too tender to thrive in this country in the open air.

The eleventh ſort was ſent me from the iſland of Barbuda. This is an annual plant, which riſes with twining ſtalks ſeven or eight feet high, garniſhed with oblong, oval, ſmooth leaves. The flowers come out at every joint on ſlender long foot-ſtalks, each ſupporting a large purple flower, whoſe empalement is cut almoſt to the bottom, in ten parts. The ſeeds and capſule are like thoſe of the other ſpecies. This is a tender plant, ſo muſt be treated in the ſame manner as the eighth ſort.

The twelfth ſort grows naturally at Carthagena in New Spain, from whence I received the ſeeds. This is a perennial plant, which riſes with ſtrong winding ſtalks to the height of twelve or fourteen feet, and are garniſhed with leaves, divided into five lobes, ſtanding upon ſhort foot-ſtalks; the flowers ſtand upon long foot-ſtalks, each ſuſtaining two purple flowers. The ſtalks, leaves, and every part of the plant, is cloſely covered with pungent ſtinging hairs, of a light brown colour. This ſort is tender, ſo muſt be treated in the ſame way as the eighth.

The thirteenth ſort grows naturally about Tolu in New Spain, from whence the ſeeds were ſent me by the late Mr. Robert Millar. This hath a ligneous ſtalk covered with a purple bark, which twines about the trees, and riſes to the height of thirty feet or more, and is garniſhed with leaves, which are deeply divided into five ſharp-pointed lobes. The flowers ſtand upon long thick foot-ſtalks, which have a knee in the middle; they are very large, and of a purple colour; theſe are ſucceeded by round ſeed-veſſels, as large as a middling Apple, divided into three cells, each containing two very large ſmooth ſeeds.

This plant is too tender to thrive in the open air in England, ſo muſt be treated in the ſame manner as the eighth ſort, but it grows too tall for the ſtoves here. I have had theſe plants upward of twenty feet high, which have ſent out many ſide branches, extending ſo wide on every ſide, as to cover moſt of the neighbouring plants, ſo that I was obliged to remove them into a cooler ſituation, where they would not thrive.

The fourteenth ſort grows naturally on the ſea ſhores in moſt of the iſlands in the Weſt-Indies, where the ſtalks trail on the ground, which are garniſhed with oval leaves, indented at the top. The flowers are large, of a purple colour, and are produced by threes, on very long foot-ſtalks; theſe are ſucceeded by large oval ſeed-veſſels, with three cells, each containing a ſingle ſeed. This hath a perennial ſtalk, which trails on the ground, and ſpreads to a great diſtance, but is too tender to thrive in the open air in England, ſo muſt be treated in the ſame manner as the eighth ſort, and may be continued two or three years in a warm ſtove; but it is apt to ſpread too far for a ſmall ſtove, ſo that where there is not great room, it is not worthy of culture.

The fifteenth ſort grows naturally in Jamaica; this riſes with ſlender twining ſtalks eight or ten feet high; the leaves of theſe are ſhaped a little like thoſe of the common great white Convolvulus, but the foot-ſtalks, which are pretty long, do each ſuſtain many purple flowers, growing in bunches. The ſeed-veſſels of this ſort are three-cornered, and have three cells, each containing a ſingle ſeed. This is an annual plant, which requires a hot-bed to raiſe it, and muſt be kept in a glaſs-caſe or a ſtove, otherwiſe the ſeeds will not ripen here.

The ſixteenth ſort has been long preſerved in ſeveral curious gardens in England. It grows naturally in the Canary Iſlands; this hath a ſtrong fibrous root, from which ariſe ſeveral twining woody ſtalks, dividing into many ſmaller; theſe, where they have ſupport, will grow more than twenty feet high, and are garniſhed with oblong heart-ſhaped leaves, which are ſoft and hairy. The flowers are produced from the wings of the leaves, ſeveral ſtanding upon one foot-ſtalk; theſe are for the moſt part of a pale blue, but there is a variety of it with white flowers. This plant flowers in June, July, and Auguſt, and ſometimes ripens ſeeds here; but as the plants are eaſily propagated by layers, and alſo from cuttings, the ſeeds are not ſo much regarded; nor indeed will thoſe plants which are raiſed by layers or cuttings produce ſeeds, though thoſe which come from ſeeds ſeldom fail. As the leaves of this plant continue green all the year, the plants make a pretty variety in winter in the green-houſe; for it will not live abroad in winter in this country, though it only requires the ſame protection as Myrtles, and other hardy green-houſe plants. It may be propagated by laying down the young ſhoots in the ſpring, which generally put out roots in three or four months; then they may be taken from the old plants, and each planted in a ſeparate pot filled with light earth, and placed in the ſhade till they have taken new root; after which they may be placed with other hardy green-houſe plants till autumn, when they ſhould be removed into the green-houſe, and afterward treated in the ſame way as Myrtles, and other green-houſe plants. If the tender cuttings of this are planted during any of the ſummer months, in pots filled with light earth, and plunged into a moderate hot-bed, ſhading them from the ſun, they will take root, and afterward ſhould be treated as the layers.

The ſeventeenth ſort is an annual plant; the ſeeds of it were ſent me from Jamaica, where it grows naturally. This riſes with a very ſlender twining ſtalk four or five feet high, garniſhed with triangular leaves, which are pointed. The flowers grow in cluſters, ſitting cloſe to the ſtalks, which are blue, and are ſucceeded by ſeeds like thoſe of the fourth ſort. This ſort will not ripen ſeeds in England, unleſs the plants are brought forward on a hot-bed in the ſpring, and afterward placed in a glaſs-caſe, where they may be defended from cold.

The eighteenth ſort grows naturally in Jamaica, from whence the ſeeds were ſent me by the late Dr. Houſtoun. This is one of the moſt beautiful kinds, the flowers being very large, and of a fine Roſe colour. It riſes with a winding ſtalk ſeven or eight feet high, which is garniſhed with heart-ſhaped leaves, ending in long ſharp points, ſitting upon very long foot-ſtalks. The flowers alſo have long foot-ſtalks, each ſupporting two flowers, whoſe empalement is divided deeply into five parts; the ſeeds of this are large, and covered with a fine down. This is an annual plant, which is too tender to thrive in the open air in this country, ſo the ſeeds ſhould be ſown on a hot-bed in the ſpring, and the plants afterward treated in the ſame manner as is directed for the eighth ſort.

The nineteenth ſort grows naturally near the ſea at Campeachy, from whence I received the ſeeds. This hath ſtrong, ſmooth, winding ſtalks, which ſend out roots at their joints, and are garniſhed with arrow-pointed leaves, whoſe ears or lobes are obtuſe; the flowers are large, of a ſulphur colour, and ſit upon very long foot-ſtalks, which proceed from the ſide of the ſtalks, each ſupporting one flower, with a large ſwelling empalement; theſe are ſucceeded by large, ſmooth, oval capſules, having three cells, each including one large ſmooth ſeed. This is a perennial plant, whoſe ſtalks extend to a great diſtance, and put out roots at the joints, whereby it propagates in plenty; but it is too tender to thrive in England, unleſs it is preſerved in a warm ſtove, where it requires more room than can well be allowed to one plant. It muſt be treated in the ſame manner as the eighth ſort.

The twentieth ſort grows naturally in Africa, from whence the ſeeds were ſent to the royal garden at Paris, and from thence I received it in 1730. This riſes with a ſlender winding ſtalk five or ſix feet high, garniſhed with heart-ſhaped arrow-pointed leaves; the flowers ſtand on long ſlender foot-ſtalks; theſe are white, with purple bottoms. This ſort may be treated in the ſame manner as the common great Convolvulus.

The twenty-firſt ſort grows naturally in Spain and Italy. This is an annual plant, which riſes about two feet high, with ſlender twining ſtalks, garniſhed with oval leaves. The flowers are ſmall, and of a bluiſh colour, each foot-ſtalk ſupporting one flower of little beauty, ſo is not often cultivated in gardens. If the ſeeds of this ſort are permitted to ſcatter, the plants will riſe in the ſpring, and require no other culture but to keep them clean from weeds; or if the ſeeds are ſown in the ſpring, where the plants are to remain, they will flower in June, and the ſeeds will ripen in Auguſt.

The twenty-ſecond ſort grows naturally in Sicily, and alſo in the iſlands of the Archipelago. This hath a perennial root, which ſends out many ſlender ſtiff ſtalks, twiſting themſelves round the neighbouring plants, and riſe five or ſix feet high; theſe are garniſhed with leaves, which are divided into five or ſeven narrow lobes, and are of a ſoft texture, like ſattin, ſtanding on ſhort foot-ſtalks. The flowers are produced from the ſide of the ſtalks upon long foot-ſtalks, which ſuſtain two flowers of a pale Roſe colour, with five ſtripes of a deeper red. This ſort creeps at the root, ſo ſeldom produces ſeeds in England, but is propagated by ſhoots taken from the old plants. The beſt time for parting and tranſplanting theſe plants, is about the beginning of May, when they may be taken out of the green-houſe, and expoſed in the open air; but the young plants which are ſeparated from the old ones, ſhould be placed under a frame, and ſhaded from the ſun till they have taken new root; after which they muſt be gradually hardened to bear the open air, to which they muſt be expoſed all the ſummer; but in autumn they muſt be placed in the green-houſe, and may be treated in the ſame way as the Canary Convolvulus beforementioned.

The twenty-third ſort hath ſome appearance of the twenty-ſecond, and hath been ſuppoſed to be the ſame ſpecies by ſome writers; but I have cultivated both many years, and never have found either of them alter, ſo that I make no doubt of their being diſtinct plants. This ſort hath a perennial root like the former, which ſends out many weak twining ſtalks, riſing about three feet high, twiſting about the plants which ſtand near it, or about each other, and if they have no other ſupport, fall to the ground; theſe are garniſhed with leaves of different forms, ſome are ſhaped almoſt like thoſe of Betony, being ſlightly cut on their edges, others are almoſt heart-ſhaped, and are deeply cut on the ſides, and ſome are cut to the midrib; they have a ſhining appearance like ſattin, and are ſoft to the touch, ſtanding on ſhort foot-ſtalks. The flowers are produced on the oppoſite ſide from the leaves, having very long foot-ſtalks, each ſuſtaining two flowers of a pale Roſe colour, very like thoſe of the former ſpecies. It flowers in June, July, and Auguſt, but rarely ripens ſeeds in England. It hath a perennial root, which ſends out offſets, by which it is propagated in England, in the ſame manner as the laſt mentioned, and the plants muſt be treated in the ſame way.

The twenty-fourth ſort grows naturally in Portugal, but hath been long cultivated in the flower-gardens in England for ornament; this is uſually titled Convolvulus Minor, by the ſeedſmen and gardeners. It is an annual plant, which hath ſeveral thick herbaceous ſtalks, growing about two feet long, which do not twine like the other ſorts, but decline toward the ground, upon which many of the lower branches lie proſtrate; theſe are garniſhed with ſpear-ſhaped leaves, which ſit cloſe to the branches; the foot-ſtalks of the flowers come out juſt above the leaves at the ſame joint, and on the ſame ſide of the ſtalks; theſe are about two inches long, each ſuſtaining one large open bell-ſhaped flower, which in ſome is of a fine blue colour, with a white bottom; in others they are pure white, and ſome are beautifully variegated with both colours. The white flowers are ſucceeded by white ſeeds, and the blue by dark-coloured ſeeds, and this difference is pretty conſtant in both; but thoſe plants with variegated flowers, have frequently plain flowers of both colours intermixed with the ſtriped; therefore the only method to continue the variegated ſort, is to pull off all the plain flowers when they appear, never ſuffering any of them to remain for ſeed.

This ſort is propagated by ſeeds, which ſhould be ſown on the borders of the flower-garden where they are deſigned to remain. The uſual method is to put two or three ſeeds in each place where they are intended to flower, covering them half an inch with earth; and when the plants come up, if the ſeeds all grow, there ſhould be but two left in each place, which will be ſufficient; the others ſhould be drawn out carefully, ſo as not to diſturb the roots of thoſe which are left; after which they will require no other culture but to keep them clean from weeds. If the ſeeds are ſown in autumn, the plants will flower in May; but thoſe which are ſown in the ſpring, will not flower till about the middle of June, and will continue flowering till the froſt ſtops them. The ſeeds ripen in Auguſt and September.

The twenty-fifth ſort grows naturally in Italy and Sicily. This hath a perennial root, which runs deep in the ground, from which ariſe two or three upright branching ſtalks near two or three feet high, garniſhed with narrow leaves about two inches long, which ſit cloſe to the ſtalks; the foot-ſtalks of the flower proceed from the ſame place; theſe are four or five inches long, each ſuſtaining four or five flowers, of a pale Roſe colour, which ſpread open almoſt flat. This flowers in June and July, but ſeldom produces good ſeeds in England. It is propagated by ſeeds, which muſt be obtained from the countries where it naturally grows; theſe ſhould be ſown upon a warm dry border, where they are deſigned to remain; for as the plants run down with long tap-roots, they will not bear tranſplanting, for I have often made trial of this without any ſucceſs. When the plants come up, they ſhould be thinned where they grow too cloſe, and afterward conſtantly kept clean from weeds, which is all the culture it will require. It flowers in July and Auguſt, and the ſtalks decay in autumn; but the roots will laſt ſeveral years, and if they are in a dry ſoil and warm ſituation, will abide through the winters very well without covering. I have received a variety of this from Nice, where it grows naturally, with broader leaves, which are hairy. The flowers are placed all toward the top of the ſtalk upon long foot-ſtalks, growing many together very cloſely joined: but I cannot be ſure if it is not a ſeminal variation, for it was ſent me by the ſame title.

The twenty-ſixth ſort grows naturally in France; this hath a perennial creeping root, from which ariſe ſeveral ſhort branching ſtalks about four inches high, garniſhed with ſpear-ſhaped ſilky leaves; the flowers are produced on the ſide, and at the top of the ſtalks, in ſmall cluſters, ſitting cloſe together; theſe are much ſmaller than thoſe of the former ſort, but are of a deeper Roſe colour: this ſeldom produces ſeeds in England, but the roots propagate in plenty. It delights in a light dry ſoil, and requires no other care but to keep the plants clean from weeds; it may be tranſplanted either in the ſpring or autumn. This is by ſome ſuppoſed to be the ſame as the laſt mentioned ſort, but whoever has cultivated them, can have no doubt of their being different ſpecies.

The twenty-ſeventh ſort grows naturally in Italy, Sicily, and the iſlands in the Archipelago. It riſes with upright ſhrubby ſtalks about three feet high, cloſely garniſhed with blunt, ſpear-ſhaped, ſilky leaves, which are placed on every ſide the ſtalks; they are near two inches long, and a quarter broad, rounding at their ends. The flowers are produced in cluſters at the top of the ſtalks, ſitting very cloſe; they are of a pale Roſe colour, and come out in June and July, but do not perfect ſeeds in England. This plant will live in the open air in mild winters, if it is planted in a light ſoil and a warm ſituation, but in hard winters it is deſtroyed; therefore ſome of the plants ſhould be kept in pots, and ſheltered under a common frame in winter, where it may enjoy the free air in mild weather, and be protected from the froſt, and in ſummer placed abroad with other hardy exotic plants, where its fine ſilky leaves will make a pretty appearance. It may be propagated by laying down the branches, and alſo by cuttings, but both very ſeldom put out roots the ſame year, and many of them will fail; ſo that the beſt way is to procure the ſeeds from Italy, for thoſe plants which come from ſeeds, grow much larger than thoſe which are propagated the other way.

The twenty-eighth ſort grows naturally in Candia, and ſeveral of the iſlands in the Archipelago. This hath a perennial root, which ſends up ſeveral erect branching ſtalks about two feet high, which are garniſhed with very narrow-pointed leaves, ſitting cloſe to the ſtalks, which are hoary. The flowers come out ſingly on the ſide of the ſtalks, ſitting very cloſe to them, having ſcarce any foot-ſtalks; theſe are of a very pale bluiſh colour, and ſpread open almoſt to the bottom. It flowers in June and July, but rarely produces any ſeeds in England.

This ſort is propagated in the ſame manner as the twenty-fifth, and the plants require the ſame treatment. This plant muſt have a dry ſoil and a warm ſituation, otherwiſe it will not live through the winter in the open air in England. As the ſtalks of this ſort decay in autumn, ſo if the ſurface of the ground about their roots is covered with ſome old tanners bark, it will preſerve them in the hardeſt froſts.

The twenty-ninth ſort is uſed in medicine. This is ſtiled Soldanella, and Braſſica marina; it grows naturally on the ſea beaches in many parts of England, but cannot be long preſerved in a garden. This hath many ſmall, white, ſtringy roots, which ſpread wide, and ſend out ſeveral weak trailing branches, which twine about the neighbouring plants like the common Bindweed, and are garniſhed with kidney-ſhaped leaves about the ſize of thoſe of the leſſer Celandine, ſtanding upon long foot-ſtalks, and are placed alternate. The flowers are produced on the ſide of the branches at each joint. Theſe are ſhaped like thoſe of the firſt ſort, and are of a reddiſh purple colour; they appear in July, and are ſucceeded by round capſules, having three cells, each containing one black ſeed; every part of the plant abounds with a milky juice. This is eſteemed a good medicine to purge off watery humours, and is preſcribed in dropſies.

The thirtieth ſort grows naturally in the iſland of Ceylon. This is a perennial plant, having thick fleſhy roots, which ſpread far in the ground, and abound with a milky juice, which flows out when the roots are broken or wounded, and ſoon hardens into a reſinous ſubſtance, when expoſed to the ſun and air. From the root ſhoots forth many twining branches, which twiſt about each other, or the neighbouring plants, like the common Bindweed. Theſe are garniſhed with heart-ſhaped leaves, which are ſoft to the touch, like thoſe of the Marſh Mallow. The flowers are produced at the joints on the ſide of the ſtalks, ſeveral ſtanding together on the ſame foot-ſtalk; they are white, and ſhaped like thoſe of the common great Bindweed. Theſe are ſucceeded by round capſules, having three cells, which contain two ſeeds in each.

The roots of this plant, which is the only part uſed in medicine, are brought to us from India. It is titled Turpethum, or Turbith in the ſhops.

This plant is tender, ſo will not live in the open air in England; it is propagated by ſeeds, which muſt be ſown on a hot-bed; and when the plants are fit to remove, they ſhould be each planted in a ſeparate pot, and plunged into a hot-bed of tanners bark, and ſcreened from the ſun till they have taken freſh root, and afterward muſt be treated in the ſame manner as hath been directed for the eighth ſort.

The thirty-firſt ſort is the Jalap which is uſed in medicine. This grows naturally at Haleppo, in the Spaniſh Weſt-Indies, ſituated between La Vera Cruz and Mexico. The root of this plant hath been long uſed in medicine, but it was not certainly known, what plant it was produced from. The old title of this was Mechoacana nigra, but father Plumier aſſerted that it was the root of one ſpecies of Marvel of Peru; from whence Tournefort was induced to conſtitute a genus from that plant, under the title of Jalapa. But Mr. Ray, from better information, put it among the Convolvuli, and titled it Convolvulus Americanus, Jalapium dictus. This was by the late Dr. Houſtoun certainly aſcertained, who brought ſome of the roots of this plant from the Spaniſh Weſt-Indies to Jamaica, where he planted them, with a deſign of cultivating the plants in that iſland, where he obſerved them to thrive, during his abode there: but ſoon after he left the country, the perſon to whoſe care he committed them, was ſo careleſs as to ſuffer hogs to root them out of the ground, and deſtroy them; ſo that there was no remains of them left, when he returned there; nor have I heard of this plant being introduced into any of the Britiſh iſlands ſince.

A few years paſt I received a few of the ſeeds of this plant, which ſucceeded in the Chelſea garden, where the plants throve very well, but did not produce any flowers. This hath a large root of an oval form, which is full of a milky juice; from which come out many herbaceous triangular twining ſtalks, riſing eight or ten feet, garniſhed with variable leaves, ſome of them being heart-ſhaped, others angular, and ſome oblong and pointed. They are ſmooth, and ſtand upon long foot-ſtalks; and from a drawing of the plant, made by a Spaniard in the country, where it grows naturally, who gave it to Dr. Houſton, and is now in my poſſeſſion, the flowers are ſhaped like thoſe of the common Great Bindweed, each foot-ſtalk ſupporting one flower. But as it is only a pencil drawing, ſo the colour is not expreſſed, therefore I can give no farther account of it. The ſeeds of this are covered with very white down like cotton.

As this plant is a native of a warm country, ſo it will not thrive in England, unleſs it is preſerved in a warm ſtove; therefore the ſeeds muſt be ſown on a hot-bed, and the plants put into pots, and plunged into a hot-bed of tanners bark, and treated in the ſame manner as the eighth ſort; with this difference only, that as this hath large, fleſhy, ſucculent roots, ſo they ſhould have but little water given them, eſpecially in winter, leſt it cauſe them to rot. They ſhould be planted in light ſandy earth not too rich, for the ſame reaſon, and the plants ſhould always remain in the bark-ſtove.

The root of Jalap is eſteemed an excellent cathartic medicine, purging ſerous watery humours eſpecially, and is of ſingular ſervice in dropſies, and for rheumatic diſorders. But the quantity of the root which is uſed in medicine, is not ſufficient to render the introduction of this plant into the Britiſh colonies, a matter of great concern. But ſince the diſtillers and brewers have found out its uſe for exciting a fermentation, the conſumption of it is now ſo great, as that it would become a national benefit, if it were produced in the Britiſh iſlands; which might be ſoon effected, were the inhabitants of thoſe iſlands a little more attentive to their own, and the public benefit.

CONYZA. Lin. Gen. Plant. 854. Tourn Inſt. R. H. 454. tab. 259. [of Κώνωψ, *Gr.* becauſe the leaves, being hung up, drive away gnats and fleas, as Dioſcorides ſays:] Flea-bane.

The CHARACTERS are,

It hath a compound flower, made up of many hermaphrodite florets, which compoſe the diſk; and female half florets, which are ranged round the border, and form the rays; the hermaphrodite florets are funnel-ſhaped, and cut into five parts at the brim, which ſpread open; theſe have each five ſhort hairy ſtamina, terminated by cylindrical ſummits; in the bottom of each floret is ſituated a germen ſupporting a ſlender ſtyle, crowned by a bifid ſtigma. The female half florets or rays, are funnel-ſhaped, and cut into three parts at the top; theſe have a germen, with a ſlender ſtyle, terminated by two ſlender ſtigmas, but have no ſtamina. All theſe are included in a common ſcaly empalement, which is oblong and ſquare; the ſcales are pointed, and the outer ones ſpread open. The hermaphrodite and female florets, are each ſucceeded by one oblong ſeed, crowned with down, ſitting upon a plain receptacle, and are included in the empalement.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia ſuperflua. The plants of this ſection have hermaphrodite and female florets, which are both fruitful.

The SPECIES are,

1. CONYZA (*Squarroſa*) foliis lanceolatis acutis, caule annuo corymboſo. Hort. Cliff. 405. *Flea-bane with pointed ſpear-ſhaped leaves, an annual ſtalk, and flowers growing in roundiſh bunches.* Conyza major vulgaris. C. B. P. 265. *Common greater Flea-bane.*
2. CONYZA (*Bifrons*) foliis ovato oblongis, amplexicaulibus. Hort. Cliff. 405. *Flea-bane with oblong oval leaves embracing the ſtalks.* Eupatoria Conyzoides maxima Canadenſis, foliis caulem amplexantibus. Pluk. Alm. 141.
3. CONYZA (*Candidis*) foliis ovatis tomentoſis, floribus confertis, pedunculis lateralibus terminalibuſque. Hort. Cliff. 405. *Flea-bane with oval woolly leaves, flowers growing in cluſters, and foot-ſtalks proceeding from the ſides and terminating the ſtalks.* Conyza Cretica fruticoſa, folio molli candidiſſimo & tomentoſo. Tourn. Cor. 33.
4. CONYZA (*Lobata*) foliis inferioribus trifidis, ſuperioribus ovato lanceolatis obſolete ſerratis floribus corymboſis. Hort. Cliff. 405. *Flea bane whoſe under leaves are trifid, thoſe above oval and ſpear-ſhaped, and flowers growing in round bunches.* Conyza arboreſcens lutea, folio trifido. Plum. Cat. 9.
5. CONYZA (*Tomentoſis*) arboreſcens, foliis oblongo ovatis, tomentoſis, ſubtus cinereis, floribus terminalibus pedunculis racemoſis. *Tree Flea-bane with oblong woolly leaves, of an Aſh colour on their under ſide, and flowers terminating the branches, ſtanding upon branching foot-ſtalks.* Conyza arboreſcens, tomentoſa, foliis oblongis, floribus in ſummitatibus racemorum, ramoſis ſparſis albicantibus. Houſt. MSS.
6. CONYZA (*Salicifolius*) foliis linearibus decurrentibus ſerratis, floribus corymboſis terminalibus. *Flea-bane with narrow running leaves, and flowers in round bunches terminating the ſtalks.* Conyza herbacea, caule alato, Salicis folio, floribus umbellatis purpureis minoribus. Houſt. MSS.
7. CONYZA (*Corymboſa*) arboreſcens, foliis lanceolatis, floribus corymboſis, terminalibus pedunculis racemoſis. *Tree Flea-bane with ſpear-ſhaped leaves, and flowers growing in round bunches at the end of the ſhoots, having branching foot-ſtalks.* Conyza arboreſcens, foliis oblongis floribus ſingulis tribus floſculis conſtantibus. Houſt. MSS.

8. Conyza (*Viſcoſa*) caule herbaceo, foliis ovatis ſerratis, villoſis, floribus alaribus & terminalibus. *Flea-bane with an herbaceous ſtalk, oval, ſawed, hairy leaves, and flowers proceeding from the ſides, and at the ends of the branches.* Conyza odorata, Bellidis folio villoſa & viſcoſa. Houſt. MSS.

9. Conyza (*Arboreſcens*) foliis ovatis integerrimis acutis ſubtus tomentoſis, ſpicis recurvatis ſecundis, bracteis reflexis. Lin. Sp. 1209. *Flea-bane with entire oval-pointed leaves, woolly on their under ſide, recurved abounding ſpikes of flowers, and reflexed bractea.* Conyza fruticoſa, flore pallide purpureo, capitulis & lateribus ramulorum ſpicatum exeuntibus. Sloan. Cat. Jam. 124.

10. Conyza (*Symphytifolia*) foliis oblongo ovatis ſcabris, floribus racemoſis terminalibus, caule herbaceo. *Flea-bane with oblong, oval, rough leaves, flowers growing in bunches at the ends of the branches, and an herbaceous ſtalk.* Conyza Symphyti facie, flore luteo. Houſt. MSS.

11. Conyza (*Scandens*) foliis lanceolatis ſcabris, nervoſis ſeſſilibus, racemis recurvatis, floribus adſcendentibus, pedunculis lateralibus caule fruticoſo ſcandente. *Flea-bane with rough, nervous, ſpear-ſhaped leaves ſitting cloſe to the branches, recurved ſpikes, with flowers ſtanding upward, foot-ſtalks proceeding from the ſide of the branches, and climbing ſhrubby ſtalks.* Conyza Americana ſcandens, Lauri folio aſpero, floribus ſpicatis albis. Houſt. MSS.

12. Conyza (*Trinerviis*) foliis ovatis glabris, trinerviis integerrimis, floribus ſpicatis terminalibus, caule fruticoſo. *Flea-bane with oval ſmooth leaves, which have three veins and are entire, flowers growing in ſpikes at the ends of the branches, and a ſhrubby ſtalk.* Conyza Americana fruteſcens, foliis ovatis trinerviis & integris, floribus ſpicatis albis. Houſt. MSS.

13. Conyza (*Uniflora*) foliis lanceolatis acutis ſeſſilibus, floribus ſingulis lateralibus, calycibus coloratis, caule fruticoſo ramoſo. *Flea-bane with pointed ſpear-ſhaped leaves ſitting cloſe to the branches, ſingle flowers on the ſide of the branches, which have coloured empalements, and a ſhrubby branching ſtalk.* Conyza Americana fruteſcens foliis oblongis acutis, capitulis & ramulorum exeuntibus, calycibus purpuraſcentibus. Houſt. MSS.

14. Conyza (*Spicata*) fruticoſa foliis ovatis trinerviis, floribus ſpicatis alaribus. *Shrubby Flea-bane with oval leaves having three nerves, and flowers growing in ſpikes from the ſide of the branches.*

15. Conyza (*Pedunculata*) foliis ovato lanceolatis trinerviis, pedunculis longiſſimis terminalibus floribus corymboſis. *Flea-bane with oval ſpear-ſhaped leaves having three veins, foot-ſtalks which are very long terminating the branches, and flowers growing in round bunches.*

16. Conyza (*Baccharis*) foliis ovato oblongis, obtuſis ſerratis, ſemiamplexicaulibus, floribus corymboſis terminalibus. *Flea-bane with oblong oval leaves which are obtuſe and ſawed, half embracing the ſtalks with their baſe, and flowers in round bunches terminating the ſtalks.* Eupatorium Conyzoides Sinica Baccharidis folio rarius crenato, ſummo caule ramoſo, floribus parvis coronato. Pluk. Amath. 80.

17. Conyza (*Odorato*) foliis lanceolatis ſerratis, petiolatis, caule fruticoſo ramoſo, floribus corymboſis terminalibus. *Flea-bane with ſpear-ſhaped ſawed leaves having foot-ſtalks, and flowers growing in round bunches at the end of the branches.* Conyza major odorato ſive Baccharis floribus purpureis nudis. Sloan. Cat. Jam. 121.

18. Conyza (*Hirſuta*) foliis ovalibus integerrimis ſcabris ſubtus hirſutis. Lin. Sp. 1209. *Flea-bane with oval, entire, rough leaves, hairy on their under ſide.*

The firſt ſort grows naturally upon dry places in ſeveral parts of England, ſo is ſeldom allowed a place in gardens. This is a biennial plant, which decays ſoon after the ſeeds are ripe; it hath ſeveral large, oblong, pointed leaves, growing near the ground, which are hairy; between theſe the ſtalks come out, which riſe two feet and a half high, dividing upward into ſeveral branches, garniſhed with ſmaller oblong leaves, ſtanding alternate; at the ends of the ſtalks the flowers are produced in round bunches, which are of a dirty yellow colour; theſe are ſucceeded by oblong ſeeds, crowned with down. It flowers in July, and the ſeeds ripen in autumn. If the ſeeds are permitted to ſcatter, the plants will come up the following ſpring, and require no other care but to keep them clean from weeds.

The ſecond ſort grows naturally on the mountains in Italy, and is preſerved in botanic gardens for the ſake of variety. This hath a biennial root but an annual ſtalk. From a thick fibrous root ariſe many upright ſtalks, garniſhed with oblong oval leaves, which are rough, and embrace the ſtalks with their baſe; theſe have appendages running along the ſtalk, from one to the other, whereby the ſtalk is winged. The upper part of the ſtalks divide into many ſmaller branches, garniſhed with leaves of the ſame form as the other, but ſmaller, ſtanding alternate; the branches and main ſtalks, are terminated by yellow flowers growing in round bunches; theſe are ſucceeded by oblong ſeeds, crowned with down. It flowers in July, and the ſeeds ripen in autumn. This is propagated by ſeeds, which may be ſown on a bed of light earth in the ſpring, and when the plants come up, they ſhould be thinned where they are too near, and kept clean from weeds; the following autumn they may be tranſplanted where they are deſigned to remain, and require no other care but to keep them clean from weeds. The ſecond year they will flower and produce ripe ſeeds, and will continue two years if the ſoil is not too good, for theſe plants often rot, when they are planted in a rich ſoil.

The third ſort grows naturally in Crete. This hath a ſhort ſhrubby ſtalk, which in this country ſeldom riſes more than ſix inches high, dividing into ſeveral ſhort branches, which are cloſely garniſhed with oval, woolly, very white leaves; from theſe branches ariſe the flower-ſtalks, which are woolly, about nine inches high, garniſhed with ſmall, oval, white leaves, placed alternate. The flowers are produced at the ſides, and end of the ſtalk, ſometimes but one, at other times two, and ſometimes three flowers ſtanding on the ſame foot-ſtalk. They are of a dirty yellow colour, and appear in July, but rarely are ſucceeded by ſeeds in this country; ſo the plant is propagated here by ſlips, which, if taken from the old plants in June, and planted on an eaſt-aſpected border, and covered with hand-glaſſes, will take root in ſix or eight weeks. But theſe ſlips muſt be frequently, but gently refreſhed with water, and the glaſſes ſhould be ſhaded in hot weather; and after they have been planted a fortnight, the glaſſes ſhould be raiſed on one ſide to admit air to the cuttings; and when they have taken root, they ſhould be gradually expoſed to the open air. In autumn theſe ſhould be carefully taken up, preſerving the earth to their roots; ſome of them may be planted in pots, that they may be ſheltered under a frame in the winter; and the others ſhould be planted in a warm border of dry poor earth, where they will endure the cold of our ordinary winters very well, and continue many years. This is preſerved in gardens, more for the beauty of its ſilvery leaves than its flowers, which have not much to recommend them.

The fourth ſort grows naturally in Jamaica, from whence it was ſent me by the late Dr. Houſtoun. This is titled by Sir Hans Sloane Virga aurea major, ſc. Herba Doria folio ſinuato hirſuto. Cat. Jam. 125. It riſes with a ſhrubby ſtalk ſeven or eight feet high, dividing into ſeveral branches, garniſhed with rough leaves four inches long, ſhaped like the point of a halbert. The flowers are produced in roundiſh bunches, at the extremity of the branches; they are yellow, and ſtand cloſe together. Theſe are ſucceeded by oblong ſeeds crowned with down.

This plant is too tender to thrive in the open air in this country, therefore the ſeeds muſt be ſown upon a hot-bed; and when the plants are fit to remove, they muſt be each tranſplanted into a ſeparate ſmall pot filled with light ſandy earth, and plunged into a hot-bed, obſerving to ſcreen them from the ſun till they have taken new root; then they muſt have free air admitted to them every day, in proportion to the warmth of the ſeaſon; they muſt alſo be frequently watered in warm weather, but they ſhould not have it in too great plenty. As the plants advance in ſtrength, ſo they muſt have a greater ſhare of air; and if the ſeaſon is warm, they may be expoſed to the open air for a few weeks in the heat of ſummer, provided they are placed in a warm ſituation; but if the nights prove cold, or much wet ſhould fall, they muſt be removed into ſhelter: if theſe plants are placed in a moderate ſtove in winter, they will thrive better than in greater heat, and in ſummer they ſhould have a large ſhare of air. With this management I have had the plants flower well in July, though they have not perfected ſeeds here.

The fifth ſort riſes with a woody ſtalk ten or twelve feet high, dividing into many branches, whoſe bark is covered with a brown down; theſe are garniſhed with oblong oval leaves, which are green on their upper ſide, but of an Aſh colour on their under, placed alternate, on ſhort foot-ſtalks. The flowers are produced at the end of the branches, upon long branching foot-ſtalks, in looſe ſpikes ranged on one ſide; they are white, and are ſucceeded by long flat ſeeds crowned with down. This plant grows naturally at La Vera Cruz in New Spain, from whence Dr Houſtoun ſent me the ſeeds. It is a tender plant, ſo muſt be treated in the ſame manner as hath been directed for the former ſort.

The ſixth ſort grows naturally at La Vera Cruz in New Spain. This hath a perennial root, from which ariſe ſeveral upright ſtalks three feet high, garniſhed with long narrow leaves, ſawed on their edges, placed alternate, and have appendages which run along the ſtalk from one to the other, forming a border or wing to the ſtalks. The flowers are produced at the end of the ſtalks in round bunches, they are ſmall, and of a purple colour, and are ſucceeded by oblong flat ſeeds, crowned with down. This is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and the plants muſt afterward be tranſplanted into pots, and plunged into a freſh hot-bed, obſerving to ſcreen them from the ſun till they have taken freſh root; after which they muſt have a large ſhare of air, and about Midſummer they may be placed in the open air in a ſheltered ſituation, where they may remain till the end of September, when they ſhould be removed into the ſtove, and during the winter kept in a temperate degree of warmth. The ſecond year theſe plants will flower, but they do not perfect ſeeds in England.

The ſeventh ſort was ſent me from La Vera Cruz by the late Dr. Houſtoun, who found it growing there naturally. This hath a ſtrong woody ſtem, which riſes to the height of fourteen or ſixteen feet, covered with an Aſh-coloured bark, and is divided upward into many ligneous branches, garniſhed with ſpear-ſhaped leaves ſtanding alternate, on ſhort foot-ſtalks. Theſe branches are terminated by roundiſh bunches of white flowers, ſitting upon long foot-ſtalks, ſeveral of them being joined on the ſame foot-ſtalk. Theſe are not ſucceeded by ſeeds in England, ſo that the ſeeds muſt be procured from abroad, and theſe muſt be ſown on a hot-bed, and the plants afterward treated in the ſame manner as the fourth ſort.

The eighth ſort grows naturally at La Vera Cruz, from whence it was ſent me by the late Dr. Houſtoun; this is an annual plant, which grows in low moiſt places, where the water ſtands in winter; it hath an herbaceous branching ſtalk, which riſes about one foot high, garniſhed at each joint with one oval leaf, ſitting cloſe to the branches; theſe are ſawed on their edges, and covered with a white hairy down. The flowers are produced from the ſide of the branches on ſlender foot-ſtalks, each for the moſt part ſuſtaining three flowers, which are white, and are ſucceeded by chaffy ſeeds, crowned with down; the whole plant is viſcous, and will ſtick to the fingers of thoſe who handle it.

The ſeeds of this plant muſt be ſown on a hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each tranſplanted into a ſeparate pot, and plunged into a freſh hot-bed, and treated in the ſame manner as the other tender ſorts, but muſt have a large ſhare of air in warm weather, and frequently refreſhed with water. In July theſe plants will flower, and if the autumn proves favourable, they will ripen their ſeeds; a plant or two of this ſort may be preſerved for the ſake of variety, but there is little beauty in it.

The ninth ſort grows naturally in Jamaica, from whence the ſeeds were ſent me by the late Dr. Houſtoun; this riſes with a ſhrubby ſtalk ſix or ſeven feet high, dividing into many ligneous branches, which have a mealy bark, and garniſhed with ſpear-ſhaped leaves, ſitting cloſe to the branches; they are hairy, and of a ſilver colour on their under ſide, and are placed alternate. The flowers come out from the ſide of the branches, generally in looſe ſpikes, which grow horizontal, and ſtand on the upper ſide erect; but ſometimes they come out ſingle, ſitting cloſe between the leaf and branch; theſe are of a pale purple colour, and are ſucceeded by chaffy ſeeds, crowned with a down.

This ſort is propagated by ſeeds, which muſt be obtained from the country where it grows naturally, for it doth not produce ſeeds in England, though it has flowered ſeveral years in the Chelſea garden; the ſeeds muſt be ſown, and the plants afterward treated in the ſame manner as hath been before directed for the fourth ſort.

The tenth ſort grows naturally at La Vera Cruz, from whence it was ſent me by the late Dr. William Houſtoun; this hath a perennial root, and an annual ſtalk. It grows about three feet high; the leaves are from four to five inches long, and one and a half broad in the middle, and are rough like thoſe of Comfrey. The ſtalks are terminated by branching flower-ſtalks, each foot-ſtalk ſuſtaining ſeveral yellow flowers, not much unlike thoſe of the common ſort. This is propagated by ſeeds in the ſame manner as the ſixth ſort, and the plants muſt be treated in the ſame way. It will flower the ſecond year, but it doth not ripen ſeeds in England.

The eleventh ſort was ſent me from La Vera Cruz by the late Dr. Houſtoun; this hath a climbing ſhrubby ſtalk, which riſes fourteen or ſixteen feet high, and divides into many branches, garniſhed with leaves about the ſize of thoſe of the Bay-tree, and full as thick in their texture, having many deep tranſverſe nerves, running from the midrib to the ſides; they are of a pale green colour. The flowers are produced in long ſpikes, ranged on the upper ſide of the ſpike only, which come out from the ſide of the branches, pointed upward; theſe are large and white, and are ſucceeded by flat dark-coloured ſeeds, crowned with down.

This plant makes a fine appearance in the ſtove when it flowers, and as it retains its leaves all the year, ſo in the winter ſeaſon it affords an agreeable variety among other tender plants. The culture of this plant is the ſame as hath been directed for the fourth ſort, ſo need not be repeated.

The twelfth ſort was ſent me from Carthagena in New Spain, where it grows naturally, by the late Mr. Robert Millar, ſurgeon; this riſes with a ſhrubby ſtalk ſix or ſeven feet high, dividing into ſeveral ligneous branches, garniſhed with oval, ſmooth, entire leaves, having three longitudinal veins, placed alternate, cloſe to the branches. The flowers are produced in ſhort cloſe ſpikes at the end of the branches; theſe are white, and are ſucceeded by oblong flat ſeeds, crowned with down; this ſort is tender, ſo muſt be treated in the ſame manner as the fourth, and will abide ſeveral years with this management.

The thirteenth ſort grows naturally in the ſame country as the laſt mentioned, and was ſent me by the ſame gentleman; this riſes with a ſhrubby ſtalk eight or ten feet high, dividing into many long ſlender branches, garniſhed with ſpear-ſhaped leaves, three inches long, and three quarters of an inch broad in the middle, ending in acute points; the ſmaller branches are ſet with very narrow, oblong, pointed leaves, which grow cloſe to the ſtalks; and at each joint is produced one pretty large white flower, with a purple empalement; theſe flowers come out the whole length of the ſmall branches, ſitting cloſe to the baſe of the leaves, ſo that the plants make a pretty appearance in flower. This may be propagated in the ſame way as the fourth, and with that management it hath flowered very well, but it doth not produce ſeeds in England.

The fourteenth ſort was ſent me from Carthagena by the before-mentioned gentleman, who found it growing there in great plenty. This hath a ſtrong woody ſtem, riſing ten or twelve feet high, divided upward into many ſhort ligneous branches, whoſe joints are very cloſe to each other. The leaves come out alternate on every ſide the branches, to which they ſit very cloſe; they are ſmooth, one inch long, and half an inch broad, ending in acute points, having three longitudinal veins. The flowers are white, and produced in ſhort cloſe ſpikes, which come out from the ſide of the branches, and are ſucceeded by oblong flat ſeeds, crowned with down.

This is a tender plant, ſo requires the ſame treatment as the fourth ſort, with which it hath flowered very well, but hath not produced ſeeds in England.

The fifteenth ſort riſes with a ſhrubby ſtem to the height of ſix or ſeven feet, dividing into ſeveral branches, which have a dark brown bark, and are cloſely garniſhed with oval, ſpear-ſhaped, ſmooth leaves, having three longitudinal veins, ſtanding on ſhort foot-ſtalks, placed alternate on every ſide the branches. The flowers are produced on long naked foot-ſtalks, which extend five or ſix inches beyond the end of the branches; theſe are purple, and form a kind of round bunch: the empalement of the flower is compoſed of ſhort chaffy ſcales.

This grows naturally at Campeachy, from whence the ſeeds were ſent me by Mr. Robert Millar. It is a tender plant, ſo muſt be treated in the ſame way as is directed for the fourth ſort, with which it hath flowered, but hath not produced ſeeds in this country.

The ſixteenth ſort grows naturally at Campeachy, from whence I received the ſeeds; this riſes with a ſhrubby ſtalk to the height of ten or twelve feet, ſending out many ſtrong ligneous branches, covered with a dark-coloured bark, garniſhed with oblong, oval, blunt leaves, ſawed on their edges, and half embrace the ſtalks with their baſe: the flowers are purple, growing in round bunches at the end of the branches, and are ſucceeded by flat ſeeds, crowned with down.

This is alſo a tender plant, and requires the ſame treatment as the fourth ſort, with which it hath flowered, but doth not produce ſeeds in England.

If the ſeeds of theſe plants are ſown in autumn ſoon after they are ripe, there is no danger of their miſcarrying; but as theſe are moſt of them brought from abroad, they do not arrive here in good time, ſo the plants rarely come up the firſt year; therefore the ſeeds ſhould be ſown in pots, that they may be preſerved through the winter, and the following ſpring the plants will come up.

The ſeventeenth ſort grows naturally in Jamaica; this riſes with a ſhrubby branching ſtalk about four or five feet high. The lower branches and ſtalk are garniſhed with ſpear-ſhaped leaves about four inches long, and one broad in the middle; they are ſawed on their edges, and have ſhort foot-ſtalks; the leaves on the upper branches are much narrower, and end in acute points. The flowers are purple, and are produced in round bunches at the end of the branches, and are ſucceeded by downy ſeeds like the other ſpecies. This is tender, and requires the ſame culture as the fourth ſort.

The ſeventeenth ſort grows naturally in China: this is a biennial plant, which periſhes ſoon after the ſeeds are ripe. The ſtalks are hairy, riſing about two feet high, garniſhed with oblong oval leaves, which are entire, rough on their upper ſide, but have many ſtrong pale hairs on their under, placed alternately on the branches. The flowers are purple, coming out from the ſide of the branches in oblong ſpikes.

This ſort is propagated by ſeeds, which ſhould be ſown in pots in the autumn, if they can be procured at that ſeaſon; but the pots ſhould be placed in a garden-frame in winter, to prevent the ſeeds ſuffering by cold and wet. If the ſeeds are ſown in the ſpring, the plants rarely come up the ſame year, therefore it will be proper to ſcreen this in winter; when this is obſerved, the plants will riſe the following ſpring. When the plants are fit to remove, they ſhould be each planted in a ſeparate pot, and placed into a very moderate hot-bed, where they muſt be ſcreened from the ſun until they have taken root; after which they ſhould be gradually hardened to bear the open air, into which they ſhould be removed the beginning of June, placing them in a ſheltered ſituation, where the ſecond ſeaſon they will flower, and if the ſummer is good, they will ripen their ſeeds.

CONVAL LILY. See Convallaria.

COPAIFERA, the balſam of Capevi.

The Characters are,

It hath no empalement; the flower conſiſts of five leaves, which expands in form of a Roſe; it hath ten ſhort ſtamina, crowned by long ſummits. The pointal is fixed in the center of the flower, which afterward becomes a pod, in which are contained one or two ſeeds, which are ſurrounded with a pulp of a yellow colour.

We know but one ſort of this tree, which is,

Copaifera (*Officinalis*) foliis pinnatis. *The balſam of Capevi.*

This tree grows near a village called Ayapel, in the province of Antiochi, in the Spaniſh Weſt-Indies; this is about ten days journey from Carthagena. There are great numbers of theſe trees in the woods about this village, which grow to the height of fifty or ſixty feet. Some of theſe trees do not yield any of the balſam, thoſe which do are diſtinguiſhed by a ridge which runs along their trunks; the trees are wounded in their center, and they place calabaſh ſhells, or ſome other veſſels to the wounded part to receive the balſam, which will all flow out in a ſhort time. One of theſe trees will yield five or ſix gallons of the balſam; but though theſe trees will thrive well after being tapped, yet they never afford any more balſam.

As this balſam is uſed in medicine, it deſerves our application to procure the trees, and cultivate them in ſome of the Engliſh colonies of America; for as the Engliſh are poſſeſſed of lands in ſo many different latitudes, they might cultivate moſt kinds of trees and plants from the different parts of the world, which are uſeful in medicine, dyeing, or for any other purpoſe of life.

The ſeeds of this tree were brought from the country of their growth by Mr. Robert Millar, ſurgeon, who ſowed a part of them in Jamaica, which he informed me had ſucceeded very well; ſo that we may hope to have theſe trees propagated in great plenty in a few years, in ſome of the Engliſh colonies, if the ſlothfulneſs of the inhabitants doth not ſuffer them to periſh, as they have the Cinnamon-tree, and ſome other uſeful plants, which have been carried thither by curious perſons.

There are not at preſent any of theſe trees in Europe, that I can learn; for thoſe ſeeds which Mr. Millar ſent over to England, were all deſtroyed by inſects in their paſſage, ſo that not one ſucceeded in the ſeveral places where they were ſown; but could freſh ſeeds be procured, the plants might be raiſed in England, and preſerved in the bark-ſtoves very well; for the country of their growth is much more temperate than many others, from whence we have been furniſhed with a great variety of plants, which ſucceed very well in the ſtoves, and ſome of them arrive to a great degree of perfection.

CORALLODENDRON. See ERYTHRINA.

CORCHORUS. Lin. Gen. Plant. 675. Tourn. Inſt. 259. tab. 135. Jews Mallow.

The CHARACTERS are,

The empalement of the flower is compoſed of five narrow ſpear-ſhaped leaves, which are erect. The flower hath five oblong blunt petals, which are no longer than the empalement. It hath many hairy ſtamina, which are ſhorter than the petals, terminated by ſmall ſummits. In the center is ſituated an oblong furrowed germen, ſupporting a ſhort thick ſtyle, crowned by a bifid ſtigma. The germen afterward becomes a cylindrical pod having five cells, which are filled with angular-pointed ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's thirteenth claſs, intitled Polyandria Monogynia, the flowers having many ſtamina and but one ſtyle.

The SPECIES are,

1. CORCHORUS (*Olitorius*) capſulis oblongis, ventricoſis, foliorum infimis ſerraturis ſetaceis. Lin. Flor. Zeyl. 213. *Jews Mallow with oblong ſwelling pods, and the ſaws on the under ſide of the leaves terminating with briſtles.* Corchorus ſive Melochia. J. B. 2. 982. *Common Jews Mallow.*
2. CORCHORUS (*Æſtuans*) capſulis oblongis, ſexſulcatis ſexcuſpidatis, foliis cordatis infimis ſerraturis ſetaceis. Lin. Sp. 746. *Jews Mallow with oblong furrowed pods, heart-ſhaped leaves, whoſe ſaws terminate with briſtles.* Corchorus Americana, carpini foliis, ſextuplici capſula prælonga. Pluk.
3. CORCHORUS (*Capſularis*) capſulis ſubrotundis, depreſſis, rugoſis. Flor. Zeyl. 214. *Jews Mallow with roundiſh depreſſed capſules which are rough.* Corchorus Americana, prælongis foliis, capſula ſtriata ſubrotunda brevi. Pluk.
4. CORCHORUS (*Tetragonis*) foliis ovato-cordatis crenatis, capſulis tetragonis, apicibus reflexis. *Jews Mallow with oval heart-ſhaped leaves which are crenated, and four-cornered capſules, whoſe points are reflexed.* Corchorus flore flavo, fructu carophylloide. Pluk.
5. CORCHORUS (*Linearibus*) foliis lanceolatis, ſerrato dentatis, capſulis linearibus, compreſſis, bivalvibus. *Jew Mallow with ſpear-ſhaped leaves, which are indented like the teeth of a ſaw, and narrow, compreſſed, bivalvular pods.*
6. CORCHORUS (*Bifurcatis*) foliis cordatis, ſerratis, capſulis linearibus, compreſſis, apicibus bifurcatis. *Jews Mallow with heart-ſhaped ſawed leaves, and narrow compreſſed pods, whoſe points have two horns.*
7. CORCHORUS (*Siliquoſus*) capſulis linearibus compreſſis, foliis lanceolatis æqualiter ſerratis. Lin. Sp. 746. *Jews Mallow with compreſſed capſules, and ſpear-ſhaped leaves equally ſawed on their edges.* Corchorus Americana, foliis & fructu anguſtioribus. Tourn. Inſt. R. H. 259.
8. CORCHORUS (*Hirſuta*) capſulis ſubrotundis lanatis, foliis ovatis obtuſis tomentoſis æqualiter ſerratis. Lin. Sp. 747. *Jews Mallow with roundiſh downy pods, and obtuſe, oval, woolly leaves, which are equally ſawed on their edges.* Corchoro affinis Chamædryos folio, flore ſtamineo, ſeminioribus atris quadrangulis duplici ſerie diſpoſitis. Sloan. Cat. 50.

The firſt ſpecies, Rauwolf ſays, is ſown in great plenty about Aleppo, as a pot-herb, the Jews boiling the leaves of this plant to eat with their meat; this he ſuppoſes to be the Olus Judaicum of Avicenna, and the Corchorum of Pliny.

This plant grows in the Eaſt and Weſt-Indies, from both which places I have ſeveral times received the ſeeds. In the Eaſt-Indies the herb is uſed in the ſame manner as in the Levant, as I have been informed; but I do not hear that it is uſed by the inhabitants of America.

It is an annual plant, which riſes about two feet high, dividing into ſeveral branches, garniſhed with leaves of different ſizes and forms; ſome are ſpear-ſhaped, others are oval, and ſome almoſt heart-ſhaped; they are of a deep green, and ſlightly indented on their edges, having near their baſe two briſtly ſegments, which are reflexed. They have very long ſlender foot-ſtalks, eſpecially thoſe which grow on the lower part of the branches. The flowers ſit cloſe on the oppoſite ſide of the branches to the leaves, coming out ſingly; they are compoſed of five ſmall yellow petals, and a great number of ſtamina ſurrounding the oblong germen, which is ſituated in the center of the flower, and afterward turns to a rough ſwelling capſule, two inches long, ending in a point, opening in four cells, which are filled with angular greeniſh ſeeds. This plant flowers in July and Auguſt, and the ſeeds ripen in autumn.

The ſecond ſort grows naturally in ſeveral iſlands of the Weſt-Indies, from whence the ſeeds have been ſent me; this is alſo an annual plant, which riſes with a ſtrong herbaceous ſtalk two feet high, divided upward into two or three branches, garniſhed with heart-ſhaped leaves, ſawed on their edges, ſtanding upon long foot-ſtalks; and between theſe are ſeveral ſmaller leaves nearly of the ſame form, ſitting cloſe to the branches. The flowers come out ſingly on the ſide of the branches, as the other, which are ſhaped like them, and are ſucceeded by longer ſwelling pods, which are rough, and have four longitudinal furrows; theſe open into four parts at the top, and contain four rows of angular ſeeds. It flowers and ſeeds at the ſame time with the former ſort.

The third ſort grows naturally in both Indies; I have received the ſeeds of this from ſeveral parts of India and America; this is alſo an annual plant, which riſes with a ſlender herbaceous ſtalk about three feet high, ſending out ſeveral weak branches, which are garniſhed at each joint by one leaf of an oblong heart-ſhape, ending in a long acute point, and are ſawed on their edges, ſtanding upon ſhort foot-ſtalks. The flowers come out ſingly on the ſide of the branches, to which they ſit very cloſe; they are ſmaller than thoſe of the former ſorts, and are ſucceeded by ſhort roundiſh ſeed-veſſels, which are rough, and flatted at the top, having ſix cells filled with ſmall angular ſeeds. This flowers and ſeeds at the ſame time as the former.

The fourth ſort is alſo a native of both Indies, from whence I have received the ſeeds; this is an annual plant, which riſes about two feet high, dividing into ſmall branches, garniſhed with oval heart-ſhaped leaves, ſawed on their edges. The flowers of this are very ſmall, of a pale yellow, and are ſucceeded by ſwelling, rough, four-cornered ſeed-veſſels, about an inch long, flatted at the top, where there are four horns, which are reflexed, ſo that theſe have ſome reſemblance in ſhape to the Clove. This flowers and ſeeds about the ſame time as the former ſorts.

The ſeeds of the fifth ſort were ſent me from Carthagena in New Spain, where the plants grow naturally; this is an annual plant, which riſes about three feet high, ſending out ſeveral weak ſide branches, garniſhed with leaves about three inches long, and one broad in the middle, leſſening gradually to both ends, and are indented on the edges like the teeth of a ſaw, ſitting cloſe to the branches. The flowers come out ſingly, oppoſite to the leaves; they are very ſmall, of a pale yellow, and are ſucceeded by ſeed-veſſels near two inches long, which are flat, and have two cells filled with ſmall angular ſeeds. This flowers and ripens its ſeeds about the ſame time as the former.

The ſeeds of the ſixth ſort were ſent me from Jamaica by the late Dr. Houſtoun; this is an annual plant, which riſes with a ſtrong herbaceous ſtalk between three and four feet high, ſending out ſeveral ſide branches, which grow erect, garniſhed with heart-ſhaped leaves ſawed on their edges, ſtanding upon long ſlender foot-ſtalks; between theſe grow many ſmaller leaves nearly of the ſame form, ſitting cloſe to the branches. The flowers come out from the ſide of the branches, on ſhort foot-ſtalks; they are very ſmall, of a pale yellow, and are ſucceeded by flat ſeed-veſſels near three inches long, ending in two horns; theſe open in two cells, which are filled with ſmall angular ſeeds.

The ſeeds of the ſeventh ſort were ſent me from Barbadoes, where the plant grows naturally, for I have alſo had it riſe in the earth which came over from thence in tubs with growing plants: this riſes about the ſame height as the ſixth, ſending out ſeveral weak ſide branches, garniſhed with long narrow leaves, which are rough, and ſawed on their edges, ſitting cloſe to the branches; between the larger leaves come out ſeveral ſmall ones, which are placed irregularly on the branches. The flowers are ſmall, of a pale yellow, and come out on the ſide of the branches oppoſite to the leaves; theſe are ſucceeded by very narrow compreſſed pods two inches long, opening with two valves, and filled with ſmall angular ſeeds. It flowers and ſeeds at the ſame time with the former.

The eighth ſort grows naturally in Jamaica; this riſes with a ſhrubby ſtalk four feet high, dividing into a great number of ſmall branches, which are cloſely garniſhed with ſmall, oval, ſawed leaves, ſitting cloſe to the branches; between theſe are many very ſmall leaves, placed without order: the flowers are produced on the ſide of the branches on very ſhort foot-ſtalks; theſe are ſmall, and the petals ſoon fall off, ſo that it has been ſuppoſed to have no petals. The flowers are ſucceeded by compreſſed ſeed-veſſels three inches long, which are rounded at their points, and open with two valves at the top, containing a great number of ſmall angular ſeeds. This plant hath a perennial ſtalk, ſo may be preſerved through the winter in a moderate ſtove, and the ſecond year will flower in June, and produce ripe ſeeds in autumn; but when the plants are brought forward ſo as to flower the firſt year, they ſeldom perfect their ſeeds, and theſe plants cannot be ſo well preſerved as thoſe which are treated hardily in the ſummer.

All theſe ſorts are too tender to thrive in England in the open air, therefore their ſeeds muſt be ſown on a hot-bed in the ſpring; and when the plants are come up fit to remove, they ſhould be tranſplanted on a freſh hot-bed to bring the plants forward, otherwiſe they will not ripen ſeeds. After the plants are rooted in the new hot-bed, they muſt have free air admitted to them every day, in proportion to the warmth of the ſeaſon, for they muſt not be drawn up weak; when the plants have obtained ſtrength, they ſhould be tranſplanted each into a ſeparate pot, and plunged into a hot-bed, obſerving to ſhade them from the ſun till they have taken root; then they muſt have a large ſhare of air every day, and ſhould be frequently refreſhed with water; and in June they ſhould be gradually inured to the open air, and part of them may be ſhaken out of the pots, and planted in a warm border, where, if the ſeaſon proves warm, they will flower and perfect their ſeeds; but as theſe will ſometimes fail, it will be proper to put one or two plants of each ſort into pots, which ſhould be placed in a glaſs-caſe, where they may be ſcreened from bad weather, and from theſe good ſeeds may always be obtained. The laſt ſort may alſo be treated in the ſame manner during the ſummer ſeaſon, but in autumn they muſt be removed into the ſtove, and plunged into the bark-bed, and theſe will flower early the ſecond year, and ripen ſeeds.

CORDIA. Plum. Nov. Gen. 13. tab. 14. Sebeſtena. Dillen. Hort. Elth. 225. Sebeſten.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, indented in three parts. It hath one funnel-ſhaped petal, whoſe tube is the length of the empalement, and the top is divided into four, five, or ſix parts, which are obtuſe and erect. It hath five awl-ſhaped ſtamina, terminated by long ſummits, and in the center a roundiſh pointed germen, ſupporting a bifid ſtyle, crowned by two obtuſe ſtigmas. The germen afterward becomes a dry berry, which is globular and pointed, faſtened to the empalement, and incloſes a furrowed nut with four cells.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The SPECIES are,

1. CORDIA (*Sebeſtina*) foliis oblongo-ovatis, repandis, ſcabris. Lin. Sp. Plant. 190. *Cordia with oblong, oval, rough leaves, turning backward.* Caryophyllus ſpurius inodorus, folio ſubrotundo, ſcabro, flore racemoſo, hexapetaloide, coccineo. Sloan. Cat. 136. *Commonly called Lignum Aloes.*
2. CORDIA (*Myxa*) foliis tomentoſis, corymbis lateralibus, calycibus decemſtriatis. Lin. Sp. 273. *Cordia with oval woolly leaves, flowers growing in a corymbus from the ſide of the branches, and empalements with ten ſtripes.* Sebeſtina domeſtica ſive Myxa. Com. Hort. Amſt. 1. 139. *The cultivated Sebeſten.*
3. CORDIA (*Macrophylla*) foliis ovatis, villoſis ſeſquipedalibus. Lin. Sp. Plant. 274. *Cordia with oval woolly leaves half a foot long.* Prunus racemoſa, foliis oblongis hirſutis maximis, fructu rubro. Sloan. Cat. Jam. 184.

The firſt ſort grows naturally in ſeveral iſlands in the Weſt-Indies: this riſes with ſeveral ſhrubby ſtalks eight or nine feet high, which are garniſhed toward the top with oblong, oval, rough leaves, ſtanding alternate on ſhort foot-ſtalks; they are of a deep green on their upper ſide. The flowers terminate the branches, growing in large cluſters upon branching foot-ſtalks, ſome ſuſtaining one, others two, and ſome have three flowers, which are large, funnel-ſhaped, having long tubes, which ſpread open at the top, where it is divided into five obtuſe ſegments; they are of a beautiful ſcarlet, ſo make a fine appearance.

The ſecond ſort is by moſt botaniſts believed to be the Myxa of Cæſalpinus, which is the beſt Sebeſten of the ſhops; the fruit of which was formerly uſed in medicine, but of late years has been ſeldom brought to England, therefore is rarely ordered. This is called Aſſyrian Plum, from the country where it naturally grows. It riſes to the height of our common Plum-trees, but was very rare in this country till the year 1762, when there was ſome of the fruit ſent from Egypt, by thoſe perſons who were ſent to travel at the king of Denmark's expence, from which fruit ſome plants have been raiſed in the Chelſea garden.

The third ſort was diſcovered by father Plumier, in ſome of the French iſlands of America; and ſince was found in the bay of Campeachy, by Mr. Robert Millar, who ſent the ſeeds to England: this ſort grows to the height of eighteen or twenty feet in the natural places where it is found wild; it hath winged leaves, which are large, entire, and ſmooth; but it hath not as yet flowered in England, ſo I can give no farther account of it.

Theſe plants, being natives of warm countries, are too tender to live through the winter in this country, unleſs they are preſerved in a ſtove: they are all propagated by ſeeds, which muſt be procured from the countries of their natural growth; theſe ſeeds muſt be ſown in ſmall pots, which muſt be plunged into a good hot-bed of tanners bark in the ſpring; and if the ſeeds are freſh and good, the plants will begin to appear in ſix or eight weeks after. Theſe muſt be brought forward in the hot-bed, by being treated as other tender exotic plants, obſerving frequently to water them in ſummer; and in July, if the plants have made much advance, they ſhould be gradually hardened, otherwiſe they will grow ſo weak as not to be eaſily preſerved through the winter. As theſe plants obtain ſtrength, they will become more hardy; but during the two firſt winters, it will be proper to plunge them into the tan-bed in the ſtove; but when they begin to have woody ſtems, they may be placed on ſhelves, in a dry ſtove; where, if they are kept in a moderate degree of heat, they may be preſerved very well (eſpecially the firſt ſort) which is ſomewhat hardier than the others. This may alſo be placed abroad in a warm ſituation, in the beginning of July, where

3

the plants may remain till the middle of September, provided the ſeaſon continues warm, otherwiſe they muſt be removed into the ſtove ſooner.

The firſt ſort produces very fine flowers, of a ſcarlet colour, in large bunches, at the extremity of the branches, after the ſame manner as the Oleander or Roſe-bay; but theſe flowers are much larger, and of a much finer colour.

A ſmall piece of the wood of this tree being put on a pan of lighted coals, will ſend forth a moſt agreeable odour, and will perfume a whole houſe.

COREOPSIS. Lin. Gen. Pl. 879. Tickſeed.

The CHARACTERS are,

The common empalement of the flower is double, the outer being compoſed of eight leaves, placed circularly; the inner is in every part larger, membranaceous, and coloured. The diſk of the flower is compoſed of many hermaphrodite florets, which are tubular, and divided into five parts at the top; theſe have each five hairy ſtamina, terminated by cylindrical ſummits. In their center is ſituated a compreſſed germen with two horns, ſupporting a ſlender ſtyle, crowned by an acute bifid ſtigma. The germen afterward becomes a ſingle orbicular ſeed, convex on one ſide, and hollow on the other, having a membranaceous border, and two horns on the top. The border or rays of the flower is compoſed of eight female florets which are large, and tongue-ſhaped, indented in five parts; theſe have no ſtamina, but a germen like the other, without any ſtyle or ſtigma, and are abortive.

This genus of plants is ranged in the third ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia Fruſtranea; the flowers of this claſs and ſection are compoſed of hermaphrodite florets which are fruitful, and female half florets which are barren.

The SPECIES are,

1. COREOPSIS (*Alternifolia*) foliis lanceolatis, ſerratis, alternis, petiolatis decurrentibus. Hort. Upſal. 270. *Tickſeed with ſpear-ſhaped ſawed leaves, placed alternate, and winged foot-ſtalks.* Chryſanthemum Virginianum, caule alato, ramoſius, flore minore. Pluk. Alm. 100.
2. COREOPSIS (*Lanceolata*) foliis lanceolatis, integerrimis ciliatis. Lin. Sp. Plant. 1283. *Tickſeed with ſpear-ſhaped leaves which are entire.* Bidens ſucciſæ folio, radio amplo laciniato. Hort. Elth. 55.
3. COREOPSIS (*Verticillata*) foliis decompoſito pinnatis, linearibus. Lin. Sp. Plant. 907. *Tickſeed with decompound, winged, narrow leaves.* Ceratocephalus delphinii foliis. Vaill. Act. 1720.
4. COREOPSIS (*Tripteris*) foliis ſubternatis, integerrimis. Hort. Upſal. 269. *Tickſeed with leaves growing by threes, which are entire.* Chryſanthemum Virginianum, folio acutiore, lævi, trifoliato, ſc. anagyridis folio. Mor. Hiſt. 3. p. 21.
5. COREOPSIS (*Radiato*) foliis lineari-lanceolatis, acutè ſerratis, oppoſitis radio amplo integro. *Tickſeed with narrow ſpear-ſhaped leaves, which are oppoſite and ſharply ſawed, and the rays of the flower large and entire.*

The firſt ſort grows naturally in North America every where. This hath a perennial root; the ſtalks decay to the root every winter, which are ſtrong, herbaceous, and riſe to the height of eight or ten feet, garniſhed with ſpear-ſhaped leaves ſawed on their edges, from three to four inches long, and one broad in the middle, placed alternate on every ſide the ſtalks, having ſhort foot-ſtalks, with a border or wing running from one to the other, the whole length of the ſtalk. The flowers grow at the top of the ſtalks, forming a ſort of corymbus, each foot-ſtalk ſuſtaining one, two, or three yellow flowers, ſhaped like Sun-flowers, but much ſmaller. This flowers in September and October, but doth not produce ſeeds in England. It is a very hardy plant, and may be propagated in plenty by parting the roots. The beſt time for this is in autumn, when the ſtalks begin to decay. It will thrive in almoſt every ſoil and ſituation.

The ſecond ſort is an annual plant. The ſeeds of this were brought me from Carolina by Mr. Cateſby, in the year 1726. This hath an upright ſtalk, garniſhed with ſmooth, narrow, ſpear-ſhaped leaves, placed oppoſite, which are entire; from the wings of the leaves come out the foot-ſtalks of the flowers, by pairs oppoſite, and ſtand erect; the lower part of theſe have one or two pair of very narrow leaves, but the upper is naked, and terminated by one large yellow flower, whoſe border or rays are deeply cut into ſeveral ſegments; theſe are ſucceeded by flat winged ſeeds, which, when ripe, roll up; the naked foot-ſtalks of theſe flowers are more than a foot long. This muſt be ſown upon a gentle hot-bed in the ſpring, and when the plants are fit to tranſplant, they ſhould be each planted into a ſeparate ſmall pot, and plunged into a freſh hot-bed to bring them forward; and in June they ſhould be inured by degrees to the open air, and afterward ſome of them may be ſhaken out of the pots, and planted in a warm border; where, if the ſeaſon is good, they will flower in the middle of July, and ripen their ſeeds the beginning of September.

The third ſort hath a perennial root, ſending up many ſtiff angular ſtalks, which riſe upward of three feet high, garniſhed at each joint with decompound winged leaves, ſtanding oppoſite; theſe are very narrow and entire. The branches alſo come out by pairs oppoſite, as do alſo the foot-ſtalks of the flowers; theſe are long, ſlender, and each terminated by a ſingle flower, of a bright yellow colour, the rays or border being oval and entire. The diſk or middle is of a dark purple colour. Theſe appear in July, and continue till September, during which time they make a fine appearance. This grows naturally in Maryland and Philadelphia. It is propagated by parting the roots, in the ſame manner as the firſt ſort, and delights in a light loamy earth, and ſunny expoſure.

The fourth ſort hath a perennial root. It grows naturally in many parts of North America, but has been long cultivated in the Engliſh gardens; the ſtalks of this are ſtrong, round, and ſmooth, riſing ſix or ſeven feet high, garniſhed at each joint with ſome trifoliate leaves, which ſtand oppoſite. The flowers are produced in bunches at the top of the ſtalks, ſtanding upon long foot-ſtalks; they are of a pale yellow, with a dark purple diſk. It flowers in July, but ſeldom produces good ſeeds in England. This ſort is propagated by parting the roots in the ſame manner as the firſt, but requires a better ſoil and poſition.

The fifth ſort grows naturally in South Carolina, from whence the ſeeds were ſent me by the late Dr. Dale. This is an annual plant, which riſes with upright ſtalks to the height of four feet, garniſhed with narrow ſpear-ſhaped leaves, ending in long points, and are deeply ſawed on their edges, ſtanding oppoſite at each joint, upon ſhort foot-ſtalks; theſe leaves are from three to four inches long, and three quarters of an inch broad in the middle, of a deep green on their upper ſide, and pale on their under. At all the upper joints of the ſtalks come out two long ſlender foot-ſtalks, one on each ſide, which are garniſhed with two or three pair of ſmall leaves, and terminated by one flower, compoſed of ſeven female half florets, which compoſe the ray; theſe are oval and entire. The diſk is compoſed of a great number of hermaphrodite florets, which are of a dark colour, and the ſummits of the ſtamina are of a bright yellow; theſe hermaphrodite florets are each ſucceeded by one flat bordered ſeed, having two horns or teeth. This ſort flowers in Auguſt, and if the autumn proves favourable, will ripen its ſeeds in October; but in cold ſeaſons it will not perfect ſeeds in England.

This is propagated by ſeeds, which ſhould be ſown on a warm border in autumn, and the plants will come up the following ſpring; for if the ſeeds are ſown in the ſpring, the plants ſeldom riſe till the year after. When the plants are fit to remove, they ſhould be carefully taken up, and either planted where they are deſigned to remain, or into a nurſery-bed, at four inches diſtance, to get ſtrength, obſerving to ſhade them from the ſun till they have taken freſh root;

after which, thoſe which are planted out for good, will require no other treatment but to keep them clean from weeds; and as they advance in height, they ſhould be ſupported by ſticks, otherwiſe the ſtrong winds in autumn often break them; and thoſe which were placed in a nurſery-bed, when they have obtained proper ſtrength, ſhould be taken up and tranſplanted with balls of earth to their roots, where they are deſigned to ſtand for flowering.

As theſe plants continue to produce flowers till the froſt puts a ſtop to them, they merit a place in every curious garden, eſpecially thoſe which do not ramble and ſpread too much. The firſt is the leaſt deſerving of either, ſo is ſeldom preſerved, but in botanic gardens for the ſake of variety.

CORIANDRUM. Lin. Gen. Plant. 318. Tourn. Inſt. R. H. 316. tab. 168. [of Κορίανδρον, of Κόρις, *Gr.* a tick; ſo called, either becauſe it has the ſcent of this inſect, or, as others ſay, becauſe it drives away or kills them; and Ἄνδρος, *Gr.* the iſle where it grew plentifully.] Coriander.

The Characters are,

It is a plant with an umbellated flower; the univerſal umbel hath but few rays, the partial umbels have many. The firſt hath no involucrum, but the latter hath a three-leaved one; the proper empalement is divided into five parts; the rays of the principal umbel are difform. The hermaphrodite flowers which form the diſk, have five equal heart-ſhaped petals, which are inflexed, but thoſe of the rays have five unequal petals of the ſame form; they have each five ſtamina, terminated by roundiſh ſummits. The germen which is ſituated under the flower, ſupports two ſtyles, crowned by ſmall radiated ſtigmas; the germen afterward becomes a ſpherical fruit, divided into two parts, each having a hemiſpherical concave ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, the flower having five ſtamina and two ſtyles.

The Species are,

1. Coriandrum (*Sativum*) fructibus globoſis. Hort. Cliff. 100. *Coriander with globular fruit.* Coriandrum majus. C. B. P. 158. *Greater Coriander.*
2. Coriandrum (*Teſticulatum*) fructibus didymis. Hort. Cliff. 100. *Coriander with twin fruit.* Coriandrum minus teſticulatum. C. B. P. 158.

The firſt of theſe ſpecies is the moſt common kind, which is cultivated in the European gardens and fields for the ſeeds, which are uſed in medicine. The ſecond ſort is leſs common than the firſt, and is ſeldom found but in botanic gardens in theſe parts of Europe. Theſe plants grow naturally in the ſouth of France, Spain, and Italy; but the firſt ſort has been long cultivated in the gardens and fields, though at preſent there is not near ſo much of it ſown in England as was ſome years paſt.

Theſe plants are propagated by ſowing their ſeeds in the autumn, in an open ſituation, on a bed of good freſh earth; and when the plants are come up, they ſhould be hoed out to about four inches diſtance every way, clearing them from weeds; by which management theſe plants will grow ſtrong, and produce a greater quantity of good ſeeds. The firſt ſort was formerly cultivated in the gardens as a ſallad herb, and in the Eaſt-Indies is ſtill much cultivated; for the plant is of great uſe in moſt of their compound diſhes, as a culinary herb, and the ſeeds are alſo much eſteemed for the like purpoſes; but in Europe neither of them are now much uſed.

The ſecond ſort will riſe eaſily from ſeeds, if they are ſown in the autumn; but thoſe which are ſown in the ſpring rarely ſucceed, or at leaſt do not come up till the following ſpring.

CORIARIA. Lin. Gen. Plant. 458. Niſſol. Act. Reg. 1711. Myrtle-leaved Sumach, vulgò.

The Characters are,

It is male and hermaphrodite in different plants; the male flowers have a five-leaved empalement; the flower has five leaves, which are joined to the empalement; theſe have ten ſlender ſtamina, terminated by oblong ſummits; the hermaphrodite flowers have the like empalement, and the ſame number of petals, and in the center are placed five pointals, which turn to a berry, incloſing five kidney-ſhaped ſeeds.

This is ranged in the ninth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Decandria, the plants having male and hermaphrodite flowers on different roots.

The Species are,

1. Coriaria (*Myrtifolia*) foliis ovato oblongis. Hort. Upſal. 299. *Myrtle-leaved Sumach, with oblong oval leaves.* Coriaria vulgaris mas. Niſſol. Act. 1711.
2. Coriaria (*Fœmina*) vulgaris fœmina. Lin. Hort. Cliff. *Female Myrtle-leaved Sumach.*

The ſort with male flowers has been the moſt common in England, the other having been very rarely raiſed in our gardens: a few years paſt, when ſome plants were raiſed from ſeeds, which came from Italy, in the Chelſea garden, where the plants ſo raiſed have moſt of them proved of the hermaphrodite ſort, and have produced great quantities of ſeeds, which have grown, though there is not one plant of the male ſort at preſent in the garden; the not finding any plants in the Engliſh gardens, but thoſe with male flowers, occaſioned my writing abroad for the ſeeds. Theſe grow wild in great plenty about Montpelier in France, where it is uſed for tanning of leather; and, from this uſe, has been titled by the botaniſts, Rhus coriariorum, i. e. Tanners Sumach.

Theſe ſhrubs ſeldom grow more than three or four feet high; and as they creep at the root, they ſend forth many ſtems, whereby they form a thicket, ſo may be planted to fill up vacancies in wilderneſs quarters; but they are improper for ſmall gardens, where they will take up too much room; and as there is no great beauty in the flowers, they are only admitted for variety.

It is ſtrange that Monſieur Niſſol, who lived upon the place where theſe grew in plenty, who conſtituted this genus, in the Memoirs of the Acadamy at Paris, has taken no notice of their being male and hermaphrodite in different plants.

It may be propagated plentifully from the ſuckers, which are produced from the creeping roots in great abundance; theſe ſhould be taken off in March, and planted into a nurſery to form good roots, where they may continue one or two years, and then muſt be removed to the places where they are to remain.

This plant delights in a loamy ſoil which is not too ſtiff, and ſhould be placed where it may have ſhelter from the north and eaſt winds; where it will endure the cold of our ordinary winters very well, and will flower better than if it is preſerved in pots and ſheltered in the winter, as hath been by ſome practiſed.

CORINDUM. See Cardiospermum.

CORIS. Lin. Gen. Plant. 216. Tourn. Inſt. 652. tab. 423. We have no Engliſh name for this plant.

The Characters are,

The empalement of the flower is of one leaf, with a ſwelling belly, but cloſed at the top, where it is divided into five parts, which are crowned by five ſpines; the flower hath one irregular petal, whoſe tube is the length of the empalement, and ſpread open at the top, where it is divided into five oblong ſegments, which are obtuſe and indented; it hath five briſtly ſtamina, terminated by ſingle ſummits. In the center is ſituated a round germen, ſupporting a ſlender declining ſtyle, crowned by a thick ſtigma; the empalement afterward becomes a globular capſule, having five valves, incloſing ſeveral ſmall oval ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

We have but one Species of this plant, viz.

Coris (*Monſpelienſis*). Hort. Cliff. 68. Coris cærulea maritima. C. B. P. 280. *Blue maritime Coris.*

There are two other varieties of this plant, one with a red, and the other a white flower, but theſe are only accidental varieties ariſing from the ſame ſeeds.

Theſe plants grow wild about Montpelier, and in many other parts of the ſouth of France, and alſo in Italy; they ſeldom grow above ſix inches high, and ſpread near the ſurface of the ground like heath; and in June, when they are full of flowers, they make a very pretty appearance.

They may be propagated by ſowing their ſeeds in the ſpring, on a bed of freſh earth; and when the plants are about an inch high, they ſhould be tranſplanted, ſome of them into pots filled with freſh light earth, that they may be ſheltered in winter; and the others into a warm border, where they will endure the cold of our ordinary winters very well, but in ſevere froſt they are generally deſtroyed; for which reaſon, it will be proper to have ſome plants of each ſort in pots, which may be put under a common hot-bed frame in winter, where they may be covered in froſty weather; but when it is mild, they ſhould have a great ſhare of free air: theſe plants ſometimes produce ripe ſeeds in England; but as they do not conſtantly perfect their ſeeds, it will be proper to increaſe them from ſlips and cuttings, which will take root, if planted about the end of Auguſt on a very gentle hot-bed, and ſhaded from the ſun and duly watered.

CORISPERMUM. Lin. Gen. Plant. 12. Juſſ. Act. R. S. 1712. Tickſeed.

The Characters are,

The flower hath no empalement, it hath two compreſſed incurved petals, which ſtand oppoſite and are equal; it hath one, two, or three ſtamina, which are ſhorter than the petals, terminated by ſingle ſummits, with a compreſſed pointed germen, ſupporting two hairy ſtyles, crowned by acute ſtigmas. The germen afterward becomes one oval compreſſed ſeed, with an acute border.

This genus of plants is ranged in the ſecond ſection of Linnæus's firſt claſs, intitled Monandria Digynia, the flower having one ſtamina and two ſtyles.

The Species are,

1. Corispermum (*Hyſopifolium*) floribus lateralibus Hort. Upſal. 2. *Tickſeed with flowers on the ſide of the ſtalks.* Coriſpermum Hyſſopifolium. Juſſ. Act. R. S. 1712. *Hyſſop-leaved Tickſeed.*
2. Corispermum (*Squarroſum*) ſpicis ſquarroſis. Hort. Upſal. 3. *Tickſeed with rough ſpikes.* Rhagroſtis foliis arundinaceis. Buxb. Cent. 3. p. 30. *Rhagroſtis with Reed-like leaves.*

Theſe plants are preſerved in botanic gardens for the ſake of variety; but as they have no beauty, are ſeldom cultivated in other gardens.

The firſt ſort is an annual plant, which, if ſuffered to ſcatter its ſeeds, the ground will be plentifully ſtocked with the plants, which will require no other care but to prevent the weeds from over-growing them.

The ſecond will not grow but in marſhy places, where there is ſtanding water; over the ſurface of which this plant will ſoon extend, when once it is eſtabliſhed.

As we had no Engliſh name to this genus, I have given it this of Tickſeed, which correſponds with the Greek name.

CORK-TREE. See Quercus.

CORN-FLAG. See Gladiolus.

CORNICULATE PLANTS [Plantæ Corniculatæ,] are ſuch, as after each flower, produce many horned ſeed-pods, called Siliquæ.

CORN-MARIGOLD. See Chrysanthemum.

CORN-SALLAD. See Valeriana.

CORNUS. Lin. Gen. Plant. 139. Tourn. Inſt. 641. tab. 410. [ſo called, of Cornu, *Lat.* a horn; becauſe its wood, or the ſhell of its fruit, is hard as a horn.] The Cornelian Cherry.

The Characters are,

It hath many flowers included in one common four-leaved involucrum, which is coloured. The flowers have each a ſmall empalement, ſitting on the germen, which is indented in four parts. They have four plain petals, which are ſmaller than the leaves of the involucrum, and four erect ſtamina, which are longer than the petals, terminated by roundiſh ſummits. The round germen ſituated below the empalement, ſupports a ſlender ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes an oval, or roundiſh berry, incloſing a nut, with two cells, having an oblong kernel.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flowers having four ſtamina and but one ſtyle.

The Species are,

1. Cornus (*Sanguinea*) arborea, cymis nudis. It. Weſtgoth. Lin. Sp. Plant. 117. *Dogwood-tree with naked ſhoots.* Cornus fœmina. C. B. P. 447. *Female Dogwood, and the Virga Sanguinea.* Matth.
2. Cornus (*Mas*) arborea, umbellis involucrum æquantibus. Hort. Cliff. 38. *Tree Dogwood with umbels equal to the involucrum.* Cornus hortenſis mas. C. B. P. 447. *Male Cornel, or Cornelian Cherry-tree.*
3. Cornus (*Florida*) arborea, involucro maximo, foliolis obverſe cordatis. Hort. Cliff. 38. *Tree Dogwood with a very large involucrum, and obverſe heart-ſhaped leaves.* Cornus mas, Virginiana, floſculis in corymbo digeſtis, à perianthio tetrapetalo albo radiatim cinctis. Pluk. Alm. 120.
4. Cornus (*Fœmina*) arborea, foliis lanceolatis, acutis, nervoſis, floribus corymboſis terminalibus. *Tree Dogwood with ſpear-ſhaped acute leaves which are veined, and flowers diſpoſed in a corymbus, terminating the branches.* Cornus fœmina Virginiana anguſtiore folio. Edit. prior. *Female Virginia Dogwood with a narrower leaf.*
5. Cornus (*Amomum*) arborea foliis ovatis petiolatis, floribus corymboſis terminalibus. *Tree Dogwood with oval leaves having foot-ſtalks, and flowers collected into a corymbus at the end of the branches.* Cornus Americana ſylveſtris, domeſticæ ſimilis, baccâ cærulei coloris elegantiſſimâ, Amomum Novæ Angliæ quorundam. Pluk. Phyt. tab. 169. f. 3. *By ſome ſuppoſed to be the true Amomum of New England.*
6. Cornus (*Candidiſſima*) arborea foliis lanceolatis, acutis, glabris, umbellis involucro minoribus, baccis ovatis. *Tree Dogwood with ſmooth, ſpear-ſhaped, pointed leaves, umbels ſmaller than the involucrum, and oval berries.* Cornus fœmina candidiſſimis foliis Americana. Pluk. Alm. 120.
7. Cornus (*Tartarica*) arborea foliis oblongo ovatis, nervoſis, infernè albis, floribus corymboſis terminalibus. *Tree Dogwood with oblong, oval, veined leaves, white on their under ſide, and flowers growing in a corymbus at the end of the branches.* Cornus ſylveſtris fructu albo. Amman. Ruth. *Wild Dogwood with a white fruit.*
8. Cornus (*Suecica*) herbacea ramis binis. Fl. Lapp. 55. *Herbaceous Dogwood with double branches.* Cornus pumila herbacea, chamæpericlymenum dicta. Hort. Elth. 108. *Low herbaceous Dogwood, called Dwarf Honeyſuckle.*

The firſt of theſe trees is very common in the hedges in divers parts of England, and is ſeldom preſerved in gardens. The fruit of this plant is often brought into the markets, and ſold for Buckthorn berries, from which it may be eaſily diſtinguiſhed, if the berries are opened to obſerve how many ſtones there are in each; which in this fruit is but one, but in the Buckthorn four, and they may be eaſily diſtinguiſhed by rubbing the juice of the berries on paper; that of the Buckthorn will ſtain the paper green, whereas the juice of this ſtains it purple. This tree is called Virga Sanguinea, from the young ſhoots being of a fine red colour. There is a variety of this tree with variegated leaves, which is preſerved in the nurſeries, but is not much eſteemed.

The ſecond ſort is very common in the Engliſh gardens, where it was formerly propagated for its fruit, which was by ſome people preſerved to make tarts. It is alſo uſed in medicine as an aſtringent and cooler: there is alſo an officinal preparation of this fruit, called Rob de Cornis. Of this there are two or three varieties, which differ only in the colour of their fruit, but that with the red fruit is the moſt common in England.

As the fruit of this tree is not at preſent much eſteemed, the nurſery-men about London propagate it as one of the ſorts which is commonly ſold as a flowering ſhrub, and is by ſome people valued for coming ſo early to flower; for if the ſeaſon is mild, the flowers will appear by the beginning of February; and though there is no great beauty in the flowers, yet, as they are generally produced in plenty, at a ſeaſon when few other flowers appear upon trees, a few plants of them may be admitted for variety. The fruit of this tree is ſeldom ripe before September. The tree will grow eighteen or twenty feet high, and make a large head.

The third ſort is an American, from whence the ſeeds have been brought to England: this is found in all northern parts of America, as are alſo the fourth, fifth, and ſixth ſorts, being natives of the woods in Virginia, New England, Maryland, and Carolina. Theſe are all of them very hardy, and thrive well in the open air in England, ſo are cultivated by the nurſery-men near London, to add to the variety of their hardy trees: theſe grow to the ſame height with our common female Dogberry, and make a much better appearance. The ſhoots of the fifth ſort are of a beautiful red colour in winter; and in ſummer the leaves being large, of a whitiſh colour on their under ſide, and the bunches of white flowers growing at the extremity of every branch, renders this ſhrub valuable; and in autumn, when the large bunches of blue berries are ripe, they make a fine appearance.

The third ſort is now very common in the nurſeries, where it is known by the name of Virginia Dogwood. This ſort is of much humbler growth than either of the former, ſeldom riſing above ſeven or eight feet high, but is generally well garniſhed with leaves, which are larger than either of the other ſorts. This does not flower ſo plentifully as the other ſorts, nor have I yet ſeen any of theſe ſhrubs, which have produced berries in England, though they are as hardy as the other.

There is a variety of this with a red involucrum or cover to the flowers, which adds to the beauty of the plant; this was found wild in Virginia by Mr. Baniſter, and afterward by Mr. Cateſby. This and the former ſort are great ornaments to the woods in America, firſt by their early flowering in the ſpring before the green leaves appear; and in the winter they are alſo beautiful when the berries are ripe, which hang upon the ſhrubs till the ſpring.

The eighth ſort grows upon Cheviot-hills in Northumberland, and alſo upon the Alps, and other mountainous places in the northern countries, but is very difficult to preſerve in gardens; the only method is, to remove the plants from the places of their natural growth, with good balls of earth to their roots, and plant them in a moiſt ſhady ſituation, where they are not annoyed by the roots of other plants. In ſuch a ſituation they may be preſerved two or three years, but it rarely happens that they will continue much longer. This is a low herbaceous plant, whoſe ſtalks decay in the autumn.

All the ſorts of Dogwood may be propagated by their ſeeds, which, if ſown in autumn ſoon after they are ripe, will moſt of them come up the following ſpring; but if the ſeeds are not ſown in autumn, they will lie a year in the ground before the plants will appear, and when the year proves dry, they will ſometimes remain two years in the ground; therefore the place ſhould not be diſturbed, where theſe ſeeds are ſown, under two years, if the plants ſhould not come up ſooner. When the plants are come up, they ſhould be duly watered in dry weather, and kept clean from weeds; and the autumn following they may be removed, and planted in beds in the nurſery, where they may remain two years, by which time they will be fit to tranſplant where they are to remain for good.

They are alſo propagated by ſuckers, and laying down the branches. Moſt of the ſorts produce plenty of ſuckers, eſpecially when they are planted on a moiſt light ſoil, which may be taken off from the old plants in autumn, and planted into a nurſery for a year or two, and then may be tranſplanted into the places where they are to remain; but thoſe plants which are propagated by ſuckers, rarely have ſo good roots as thoſe which are propagated by layers; and being much more inclinable to ſhoot out ſuckers, whereby they will fill the ground round them with their ſpawn, they are not near ſo valuable as thoſe plants which are raiſed from layers.

CORNUTIA. Plum. Nov. Gen. 17. Lin. Gen. Plant. 684. Agnanthus. Vaill. Act. R. 1722. We have no Engliſh name for this plant. It is ſo called from Cornutus, a phyſician of Paris, who publiſhed a hiſtory of Canada plants

The CHARACTERS are,

The flower hath a ſmall permanent empalement of one leaf, which is tubular, and indented in five parts at the top. The flower is of one petal, having a cylindrical tube, which is much longer than the empalement, and divided into four parts at the top; the upper ſegment is round and erect, the two ſide ones ſpread apart, and the lower is round and entire. It hath four ſtamina, two of theſe are longer than the tube, the other are ſhorter; they are terminated by inclining ſummits. In the center is ſituated the roundiſh germen, ſupporting a long ſtyle, divided into two parts, crowned by two thick ſtigmas. The germen afterward becomes a globular berry, ſitting upon the empalememt, incloſing ſeveral kidney-ſhaped ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, the flowers having two long and two ſhort ſtamina, and the ſeeds are included in a capſule.

There is but one SPECIES of this genus, viz.

CORNUTIA (*Pyramidata*). Hort. Cliff. 319. Cornutia flore pyramidato cæruleo, foliis incanis. Nov. Gen. 32. *Cornutia with a blue pyramidal flower and hoary leaves.*

This plant was firſt diſcovered by father Plumier in America, who gave it the name. It is found in plenty in ſeveral of the iſlands in the Weſt-Indies, as alſo at Campeachy and La Vera Cruz, from both which places I received the ſeeds, which were collected by my late ingenious friend Dr. William Houſtoun, and afterward by Mr. Robert Millar, from the ſame country. It grows to the height of ten or twelve feet; the branches are four-cornered, grow ſtraggling, and the leaves are placed oppoſite. The flowers are produced in ſpikes at the end of the branches, which are of a fine blue colour; theſe uſually appear in autumn, and ſometimes will remain in beauty for two months or more.

It is propagated by ſeeds, which ſhould be ſown early in the ſpring on a hot-bed; and when the plants are come up, they ſhould be tranſplanted each into a ſeparate halfpenny pot, filled with light freſh earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them until they have taken root; after which they ſhould have freſh air let into the bed, in proportion to the warmth of the ſeaſon, and ſhould be frequently watered (for it naturally grows on ſwampy ſoils.) When the plants have filled theſe pots with their roots, they ſhould be ſhifted into others of a larger ſize, and plunged into a hot-bed again, where they ſhould be continued till October, when they muſt be removed into the bark-ſtove, and plunged into the tan, for otherwiſe it will be very difficult to preſerve them through the winter. The ſtove in which theſe plants are placed ſhould be kept to the temperate heat marked on Mr. Fowler's thermometers, which will agree better with them than a hotter ſtove. The third year from ſeeds theſe plants will flower, when they make a fine appearance in the ſtove, but they never perfect their ſeeds in England.

They may alſo be propagated by cuttings, which, if planted into pots filled with earth, and plunged into a bark-bed, obſerving to ſhade and water them, will take root, and muſt be afterwards treated as the ſeedling plants.

CORONA IMPERIALIS. See FRITILLARIA.

CORONA SOLIS. See HELIANTHUS.

CORONILLA, Jointed-podded Colutea.

The CHARACTERS are,

The flower hath a ſhort permanent empalement of one leaf, which is compreſſed, bifid, and erect. It hath a *butterfly flower, whoſe ſtandard is heart-ſhaped, and reflexed on each ſide. The wings are oval, and join at the top. The keel is ſhorter than the wings, is pointed and compreſſed. It hath nine ſtamina which are united, and one ſtanding ſingle, which are broad at the top, terminated by ſmall ſummits. In the center is ſituated an oblong taper germen, ſupporting a briſtly riſing ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a taper jointed pod, incloſing oblong ſeeds.*

This genus of plants is ranged in the ſecond ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, the flower having ten ſtamina, nine of which are united, and one ſtands ſingle. To this genus Dr. Linnæus has joined the Emerus of Cæſalpinus, and the Securidaca of Tournefort, whereby he multiplies the ſpecies; but as theſe differ eſſentially in their fructification, I ſhall treat of them ſeparately, following the example of all the former botaniſts.

The Species are,

1. **Coronilla** (*Glauca*) fruticoſa, foliis ſeptenis, ſtipulis lanceolatis. Lin. Sp. 1047. *Shrubby Coronilla with ſeven pair of ſmall leaves, and ſpear-ſhaped ſtipula.* Coronilla maritima glauco folio. Tourn. Inſt. 650.
2. **Coronilla** (*Argentea*) fruticoſa foliolis undenis, extimo majore. Lin. Sp. Plant. 1049. *Shrubby Coronilla with eleven pair of ſmall leaves, the outer being the largeſt.* Coronilla argentea Cretica. Tourn. Inſt. 650.
3. **Coronilla** (*Valentina*) fruticoſa foliis ſubnovenis ſuborbiculatis. Lin. Sp. Plant. 1047. *Shrubby Coronilla with nine lobes which are orbicular.* Polygala Valentina.
4. **Coronilla** (*Hiſpanica*) fruticoſa enneaphylla, foliolis emarginatis, ſtipulis majoribus ſubrotundis. *Shrubby nine-leaved Coronilla, whoſe ſmall leaves are indented, and larger roundiſh ſtipulæ.* Coronilla ſiliquis & ſeminibus craſſioribus. Tourn. Inſt. R. H. 650.
5. **Coronilla** (*Minima*) foliolis plurimis, ovatis, caule ſuffruticoſo declinato, pedunculis longioribus. *Coronilla with many oval lobes, a declining ſtalk ſomewhat ſhrubby, and longer foot-ſtalks to the flowers.* Coronilla minima. Tourn. Inſt. R. H. 650. *Smalleſt Coronilla.*
6. **Coronilla** (*Varia*) herbacea, leguminibus erectis, teretibus, toroſis, numeroſis, foliis glabris. Hort. Cliff. 363. *Herbaceous Coronilla with many taper erect pods, and ſmooth leaves.* Coronilla herbacea flore vario. Tourn. Inſt. 650.
7. **Coronilla** (*Cretica*) herbacea, leguminibus quinis, erectis, teretibus, articulatis. Prod. Leyd. 387. *Herbaceous Coronilla with five taper, erect, jointed pods.* Coronilla Cretica herbacea, flore parvo purpuraſcente. Tourn. Cor. 44.
8. **Coronilla** (*Orientalis*) herbacea leguminibus numeroſis, radiatis, craſſioribus, articulatis, foliolis ſubtus glaucis. *Herbaceous Coronilla with many thick jointed pods diſpoſed like rays, and ſmaller leaves of a ſea-green on their under ſide.* Coronilla orientalis herbaceo, flore magno luteo. Tourn. Cor. 44.
9. **Coronilla** (*Juncea*) fruticoſa, foliis quinatis ternatiſque lineari-lanceolatis ſubcarnoſis obtuſis. Lin. Sp. 1047. *Shrubby Coronilla with five and trefoil linear, ſpear-ſhaped leaves, which are obtuſe and fleſhy.* Doricum luteum Hiſpanicum carnoſius. Barrel. Icon. 133.
10. **Coronilla** (*Scandens*) caule hirſuto, volubili, foliolis quinis ovatis, floribus binis, erectis, axillaribus, leguminibus erectis, villoſis. *Coronilla with a twining hairy ſtalk, five oval leaves, two flowers growing erect on the ſides of the branches, and upright hairy pods.* Coronilla ſcandens pentaphylla. Plum. Cat. 19. *Climbing five-leaved Coronilla.*

The firſt ſort is an humble ſhrub, which ſeldom riſes more than two or three feet high, with a ligneous branching ſtalk, garniſhed cloſely with winged leaves, each being generally compoſed of five pair of ſmall leaves (or lobes) terminated by an odd one; theſe are narrow at their baſe, and broad at the top, where they are roundiſh and indented; they are of a ſea-green colour, and continue all the year. The flowers are produced on ſlender foot-ſtalks from the wings of the leaves, on the upper part of the branches, ſeveral ſtanding together in a roundiſh bunch; they are of the butterfly, or Pea-bloom kind, and of a bright yellow colour, having a very ſtrong odour, which to ſome perſons is agreeable, but to others the contrary. This flowers in April and May, and the ſeeds ripen in Auguſt.

This plant is propagated by ſowing the ſeeds in the ſpring, either upon a gentle hot-bed, or on a warm border of light freſh earth; and when the plants are come up about two inches high, they ſhould be tranſplanted either into pots, or a bed of good rich earth, at about four or five inches diſtance every way, where they may remain until they have obtained ſtrength enough to plant out for good; which ſhould be either into pots filled with good freſh earth, or a warm ſituated border; in which, if the winter is not too ſevere, they will abide very well, provided they are in a dry ſoil.

The ſecond ſort is a ſhrub of the ſame ſize with the firſt, from which it differs in the number of ſmall leaves (or lobes) on each midrib; theſe having nine or eleven, and are of a ſilver colour, but the flowers and pods are the ſame. It flowers at the ſame time, and requires the ſame treatment as the former.

The third ſort is a ſhrubby plant, riſing four or five feet high; the ſtalks are ſhrubby garniſhed with winged leaves, compoſed of many ſmall oval lobes along the midrib by pairs, and ending in an odd one. The flowers ſtand upon long foot-ſtalks, which ariſe from the ſide of the branches; they are yellow, and grow together in cloſe bunches. This flowers in winter and ſpring, and the ſeeds are ripe in Auguſt.

This is a perennial ſhrubby plant, which is propagated by ſeeds; they may be ſown on a bed of light earth in April, and when the plants are fit to tranſplant, ſome of them ſhould be planted in a warm border, cloſe to a warm wall or pale, to which the branches ſhould be trained; obſerving to ſhade them from the ſun till they have taken freſh root, and alſo to refreſh them with water when they require it. After they are well rooted, they will require no other culture but to keep them clean from weeds, and faſten their branches to the wall; the next year they will flower, and if they are on a dry ſoil and in a warm ſituation, they will continue many years. Some of theſe plants ſhould be put into pots, that they may be removed into ſhelter in winter; where, if they are not too tenderly treated, they will flower great part of that ſeaſon; but theſe will rarely produce ſeeds, whereas thoſe in the full ground generally do, provided they are covered with mats in froſty weather.

The fourth ſort is nearly like the firſt, but hath fewer pinnæ on each midrib. The flowers are larger, and have little ſcent. The pods and ſeeds are much larger, and the plants are not quite ſo hardy. This flowers in May and June, but rarely perfects ſeeds in England; it requires the ſame treatment as the firſt, but in winter the plants ſhould be ſheltered, otherwiſe hard froſts will deſtroy them.

The fifth ſort is a low trailing plant with ſhrubby ſtalks, which ſpread near the ground, garniſhed with winged leaves, compoſed of many pair of ſmall lobes placed along the midrib, terminated by an odd one; theſe are oval, and of a bright green; the flowers ſtand upon long foot-ſtalks in cloſe bunches, they are yellow, and without ſcent. It flowers in May, and the ſeeds ripen in autumn. This is propagated by ſeeds in the ſame manner as the third, and requires the ſame treatment.

The ſixth ſort dies down every winter, but riſes again the ſucceeding ſpring; the ſtalks of this riſe to the height of five or ſix feet, where they have ſupport; otherwiſe they trail on the ground, and are garniſhed with winged leaves, compoſed of ſeveral oblong ſmall pinnæ, which are ſometimes placed by pairs, and at other times are alternate, ending in a ſingle one, they are of a deep green. The flowers come out on long foot-ſtalks from the wings of the leaves, many growing together in round bunches; they are variable from a deep to a light purple, mixed with white, and are ſucceeded by ſlender pods from two to three inches long, ſtanding erect. This plant flowers in June, July, and Auguſt, and the ſeeds ripen in autumn. The roots of this plant creep very far under ground, by which the plant increaſes greatly; which, when permitted to remain unremoved for two or three years, will ſpread and overbear what plants grow near it; for which reaſon the roots ſhould be confined, and it ſhould be planted at a diſtance from any other plants; it will grow in almoſt any ſoil and ſituation, but thrives beſt in a warm ſunny expoſure, in which the flowers will alſo be much fairer, and in greater quantities. This plant was formerly cultivated to feed cattle.

The ſeventh ſort hath an herbaceous ſtalk, which riſes two feet high, garniſhed with winged leaves, compoſed of ſix pair of ſmall leaves, placed along the midrib, which is terminated by an odd one; theſe are larger than thoſe of the ſixth ſort, and broader at the top. The foot-ſtalks of the flowers come out from the ſide of the ſtalks, but they are ſhorter than thoſe of the ſixth ſort, and ſuſtain ſmaller heads of flowers, which are ſucceeded by five taper jointed pods, near two inches long.

This is an annual plant, which grows naturally in the Archipelago, from whence Tournefort ſent the ſeeds to the royal garden at Paris. The ſeeds of this ſort ſhould be ſown on a bed of light earth in the ſpring, where the plants are deſigned to remain, and when the plants come up, they ſhould be thinned where they are too cloſe, and afterward kept clean from weeds, which is all the culture they will require. In June they will flower, and the ſeeds ripen in autumn.

The eighth ſort was diſcovered by Dr. Tournefort in the Levant, from whence he ſent the ſeeds to the royal garden at Paris; this hath a perennial root, and an annual ſtalk, which riſes upward of two feet high, ſtanding erect. The leaves are compoſed of five or ſix pair of ſmall oblong leaves, ranged along the midrib, which is terminated by an odd one. The foot-ſtalks of the flowers are ſtrong, and upward of ſix inches in length, ſupporting large bunches of yellow flowers, which are ſucceeded by ſhort thick pods about an inch long. This flowers in June and July, and in warm ſeaſons the ſeeds will ripen in autumn: there is a variety of this with large white flowers.

This ſort is propagated by ſeeds, which ſhould be ſown on a warm border of light earth in the ſpring; and when the plants come up, they muſt be carefully cleaned from weeds; when they are fit to remove, they ſhould be tranſplanted into a warm border, where they are to remain, ſhading them from the ſun till they have taken freſh root, after which they will require no farther care in ſummer, but to keep them clean from weeds; and in autumn, when the ſtalks are decayed, if the ſurface of the ground is covered with ſome old tan to keep out the froſt, it will be a ſecure method to preſerve the roots. The ſecond year the plants will flower, and, if the ſame care is taken in winter, the roots may be continued ſome years.

The ninth ſort grows naturally in Spain; this riſes from two to four feet high, having many ſlender ligneous branches, garniſhed with narrow ſpear-ſhaped leaves, which are ſometimes trifoliate, and at other times have five lobes on each foot-ſtalk; the flowers ſtand upon pretty long foot-ſtalks, which come out from the wings of the ſtalk, and are collected in ſmall bunches; they are of a bright yellow colour, and appear for ſix or ſeven months together, but have not been ſucceeded by ſeeds here as yet.

This is propagated by ſeeds in the ſame manner as the firſt ſort, and ſome of the plants ſhould be planted in pots that they may be ſheltered under a common frame in winter, becauſe in hard froſts the plants are often deſtroyed; but in mild weather they ſhould be expoſed to the air, otherwiſe they will draw up weak.

The tenth ſort was diſcovered by father Plumier in America. I received the ſeeds of this plant from Carthagena, which were ſent me by my late ingenious friend Dr. William Houſtoun; this hath a ſlender, hairy, twining ſtalk, of a brown colour, twiſting round any of the ſhrubs which ſtand near it, whereby it riſes eight or ten feet high, and is garniſhed with winged leaves, for the moſt part compoſed of five oval lobes, one inch long, and half an inch broad, of a deep green. The flowers come out by pairs at each joint, ſtanding on very ſhort ſeparate foot-ſtalks erect; they are large, and of a pale yellow; theſe are ſucceeded by taper jointed pods, more than three inches long, which are covered with ſhort, ſoft, white, hairy down, and ſtand erect. This plant is propagated by ſeeds, which ſhould be ſown early in the ſpring on a moderate hot-bed; and when the plants are come up, they ſhould be each tranſplanted into a halfpenny pot filled with freſh rich earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them until they have taken root; after which time they ſhould have air and water in proportion to the warmth of the ſeaſon, and when they have filled theſe pots with their roots, they ſhould be ſhifted into pots of a larger ſize, and plunged into the hot-bed again, where they muſt remain until autumn, when they ſhould be removed into the ſtove, and plunged into the tan. Theſe plants muſt be conſtantly kept in the bark-ſtove, and placed among plants which require a moderate heat; where they will thrive and flower, and ſhould be ſupported by tall ſticks, round which they will twine as Hops do; for if they have not this ſupport, they will twiſt round other plants and ſpoil them. Theſe are very proper plants to place againſt an eſpalier on the back part of the ſtove, amongſt other climbing plants, where they will make an agreeable variety.

If the plants are carefully managed in the winter, they may be preſerved two or three years, and will annually flower in July, and ſometimes they will produce ripe ſeeds in England.

CORONOPUS. See Plantago.

CORTUSA. Lin. Gen. Plant. 181. [This plant is ſo called from Cortuſus, a famous botaniſt, who firſt brought it into uſe.] Bears-ear Sanicle.

The Characters are,

The flower hath a ſmall, ſpreading, permanent empalement, which is indented at the brim in five parts; this hath one wheel-ſhaped petal, ſpreading open to the bottom, and cut into five parts at the brim, having five prominent tubercles at the baſe. It hath five ſhort obtuſe ſtamina, which are terminated by oblong erect ſummits. In the center is ſituated an oval germen, ſupporting a ſlender ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes an oval, oblong, pointed capſule, having two longitudinal furrows, and one cell, opening with two valves, filled with ſmall oblong ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Cortusa (*Matthioli*) calycibus corollâ brevioribus. Lin. Sp. Plant. 144. *Bears Ear Sanicle, with an empalement ſhorter than the petal.* Cortuſa Matthioli. Cluſ. Hiſt. 1. p. 307. *Bears Ear Sanicle of Matthiolus.*
2. Cortusa (*Gmelini*) calycibus corollum excedentibus. Amœn. Acad. 2. p. 340. *Bears Ear Sanicle with an empalement longer than the petal.*

The firſt ſort grows naturally on the Alps, and alſo on the mountains in Auſtria, and in Siberia. This plant ſends out many oblong ſmooth leaves, which are a little indented on the edges, and form a ſort of head, like the Auricula. The foot-ſtalks of the flowers come out in the center of the leaves; theſe riſe about four inches high, and ſupport an umbel of flowers, each ſitting on a ſlender, ſeparate, ſhort foot-ſtalk; they are of a fleſh colour, and ſpread open like thoſe of the Auricula. It flowers in April, but doth not produce ſeeds in the gardens, for this plant is with great difficulty kept in a garden. The only method by which I could ever preſerve it, has been by planting the plants in pots, and placing them in a ſhady ſituation, where they were duly watered in dry weather; in this place they conſtantly remained both ſummer and winter, for the cold will not deſtroy them; the earth for this plant ſhould be light, and not too rich, for dung is very injurious to it. As this very rarely produces any ſeeds in England, the only method to propagate it is, by parting the roots in the ſame manner as is practiſed for Auriculas; the beſt time for this is about Michaelmas, ſoon after which the leaves decay.

The ſecond ſort is very like the firſt, but the flowers are much leſs, and their empalements are larger; this grows naturally in Siberia, but is with great difficulty kept in a garden.

CORYLUS. Lin. Gen. Plant. 953. Tourn. Inſt. R. H. 581. [ſo called from Κόρυλος, *Gr.* a Hazel, or Filbert-tree. It is alſo called Avellana, from Avella, a town in Campania, where it grew in great plenty.] The Hazel, or Nut-tree.

The Characters are,

It hath male and female flowers growing at remote diſtances on the ſame tree. The male flowers are produced in long ſcaly katkins, each ſcale including a ſingle flower, having no petals, but eight ſhort ſtamina faſtened to the ſide of the ſcale, and terminated by oblong erect ſummits. The female flowers are included in the future bud, ſitting cloſe to the branches; theſe have a thick two-leaved perianthium, torn on the border, ſitting under the flower when it is ſmall, but afterward is enlarged to the ſize of the fruit; it hath no petal, but a ſmall round germen occupies the center, ſupporting two briſtly coloured ſtyles, which are longer than the empalement, crowned by two ſingle ſtigmas. The germen afterward becomes an oval nut, ſhaved at the baſe, and compreſſed at the top, ending in a point.

This genus of plants is ranged in the eighth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Polyandria, from there being male and female flowers on the ſame plant, and the male flowers having many ſtamina.

The Species are,

1. Corylus (*Avellana*) ſtipulis ovatis obtuſis. Hort. Cliff. 448. *Hazel Nut with oval blunt ſtipulæ.* Corylus Sylveſtris. C. B. P. 418. *Wild Hazel Nut.*
2. Corylus (*Maxima*) ſtipulis oblongis, obtuſis, ramis erectioribus. *Hazel with oblong blunt ſtipulæ, and the branches growing more erect.* Corylus ſativa fructu oblongo. C. B. P. 418. *The Filbert.*
3. Corylus (*Colurna*) ſtipulis linearibus acutis. Hort. Cliff. 448. *Hazel with narrow acute ſtipulæ.* Corylus Byzantina. H. L. 191. *Byzantine Nut.*

The firſt of theſe trees is common in many woods in England, from whence the fruit is gathered in plenty, and brought to the London markets by the country people. This tree is ſeldom planted in gardens (except by perſons curious in collections of trees and ſhrubs;) it delights to grow on a moiſt ſtrong ſoil, and may be plentifully increaſed by ſuckers from the old plants, or by laying down their branches, which, in one year's time, will take ſufficient root for tranſplanting; and theſe will be much handſomer and better rooted plants than ſuckers, and will greatly outgrow them, eſpecially while young.

There is a variety of this with fruit growing in great cluſters at the end of the branches, which is diſtinguiſhed by the title of Cluſter Nut; but as this is ſuppoſed to be only a variety, which accidentally came from the other, I have not diſtinguiſhed it; however, this may be continued by layers, ſo the kind may always be preſerved.

The ſecond ſort is by many ſuppoſed to be only a ſeminal variety from the firſt, which hath been improved by culture; but this is very doubtful, for I have ſeveral times propagated both from the nuts, but never have found them vary from one to the other, though they have altered in the ſize and colour of their fruit, from the ſorts which were ſown; but as the ſhrubs of this grow more erect than thoſe of the other, and the ſtipulæ are different in their ſhape, ſo I have enumerated it as a diſtinct ſort; of this there are the red and white Filberts, both which are ſo well known, as to need no deſcription.

The third ſort grows naturally near Conſtantinople; the nuts of this are large, roundiſh, and in ſhape like thoſe of the common Hazel, but are more than twice their ſize. The cups in which the nuts grow are very large, ſo as almoſt to cover the nut, and is deeply cut at the brim. This ſort is not common in England, but I take thoſe large nuts which are annually imported from Barcelona in Spain, to be of the ſame kind, the nuts being ſo alike, as not to be diſtinguiſhed when out of their cups; and thoſe of the Spaniſh ſort come over naked, ſo I cannot with certainty ſay how they eſſentially differ.

All theſe ſorts may be propagated by ſowing their nuts in February; which, in order to preſerve them good, ſhould be kept in ſand in a moiſt cellar, where the vermin cannot come at them to deſtroy them nor ſhould the external air be excluded from them, which would occaſion their growing mouldy.

The manner of ſowing the ſeeds being well known to every one, I need not here mention it, eſpecially ſince it is not the ſureſt way to obtain the ſorts deſired; for they ſeldom prove ſo good as the nuts which were ſown, or at leaſt not one in four of them will; and the method of propagating them by layers being not only the ſureſt, but alſo moſt expeditious, is what I would recommend to every one who would cultivate theſe trees for the ſake of their fruits.

CORYMBIFEROUS PLANTS are ſuch as have a compound diſcous flower, but their ſeeds have no down adhering to them. The name is taken from the manner of bearing its flowers in cluſters, and ſpreading round in the form of an umbrella. Of this kind is the Corn Marigold, common Ox Eye, the Daiſy, Camomile, Mugwort, Feverfew, &c.

Mr. Ray diſtinguiſhes them into ſuch as have a radiated flower, as the Sun Flower, Marigold, &c. and ſuch as have a naked flower, as the Lavender Cotton and Tanſey, and alſo thoſe that are akin to them, as Scabious, Teaſel, Carduus, &c.

CORYMBIUM.

The Characters are,

It hath an empalement of two leaves, having ſix angles; the ſmall leaves are erect and cloſe together their whole length, and are triangular on their outſide, cut into three ſegments, and are permanent. The flower has one petal, which is equal, having a very ſhort tube, cut into five ſegments at the brim, which ſpread open; it hath five erect ſtamina ſitting within the tube, crowned with oblong erect ſummits, ſhorter than the petal, joining in a cylinder: the germen is ſituated within the empalement, at the bottom of the petal, ſupporting a ſingle erect ſtyle the length of the petal, terminated by a bifid oblong ſtigma; the germen afterward becomes an oblong ſeed, having a ſort of down adhering to it.

This genus of plants is ranged in the ſixth ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Monogamia, the flower having five ſtamina which join by their ſummits, and is ſucceeded by one ſeed.

We know but one Species of this genus, viz.

Corymbium (*Africanum*). Hort. Cliff. 494. *African Corymbium.* Bupleurifolia ſemine papposo, valerianoides umbellata, cauliculi ſcabro. Pluk. Alm. 73.

This plant grows naturally at the Cape of Good Hope; it riſes with an erect rough ſtalk about a foot high, with a ſingle leaf at each joint, which half embrace the ſtalk with their baſe. The leaves are long, narrow, and triangular, and have a downy ſubſtance intermixed with them at their baſe; the upper part of the ſtalk divides into ſeveral foot-ſtalks, which are terminated by purple flowers of one petal, cut into five parts at the brim, each being ſucceeded by an oblong ſeed.

It is propagated by ſeeds, which ſhould be ſown in a ſmall pot filled with light earth as ſoon as it is received from abroad; the pots ſhould be plunged into a bed of tanners bark, where the heat is near ſpent, and covered with a common frame in winter, to protect the ſeeds from froſt, ſnow, and hard rains. In the ſpring, if the pots are removed into a moderate hot-bed, the plants will ſoon appear: when they are about an inch high, they ſhould be each tranſplanted into a ſeparate ſmall pot, obſerving to ſhade them until they have got new roots; ſoon after which they ſhould be gradually inured to the open air, and in June they ſhould be placed abroad in a ſheltered ſituation; where they may remain till October, when they ſhould be placed in a common frame, where they may be protected from froſt, being too tender to live abroad in England.

CORYMBUS [Κόρυμβος, *Gr.*] ſignifies among botaniſts, round cluſters of berries, as thoſe of Ivy.

Jungius uſes it to ſignify the extremity of a ſtalk, ſo ſubdivided and laden with flowers, or fruits, as to compoſe a ſpherical figure.

It is alſo by modern botaniſts uſed to ſignify a compound diſcous flower, which does not fly away in down, as the Chryſanthemum, Daiſy, Chryſocome, &c. For theſe kind of flowers, being ſpread into breadth, do, after a ſort, reſemble an umbrella, or bunch of Ivy-berries.

COSTUS. Lin. Gen. Plant. 3.

The Characters are,

It hath a ſimple ſpadix and ſpathæ, with a ſmall empalement, divided into three parts, ſitting on the germen. The flower hath three concave petals, which are erect and equal, with a large oblong nectarium of one leaf, having two lips, the lower being broad, and as long as the petal. The upper is ſhorter and ſpear-ſhaped, changing to a ſtamina; this is faſtened to the upper lip of the nectarium, to which adheres a bipartite ſummit. The germen is ſituated within the receptacle of the flower, which is roundiſh, ſupporting a ſlender ſtyle, crowned by a compreſſed indented ſtigma. The germen afterward becomes a roundiſh capſule with three cells, containing ſeveral triangular ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's firſt claſs, intitled Monandria Monogynia, the flower having but one ſtamen and one ſtyle.

We have but one Species of this plant, viz.

Costus (*Arabicus*). Hort. Cliff. 2. Coſtus Arabicus. C. B. P. 36. *Arabian Coſtus.*

This hath a fleſhy jointed root like that of Ginger, which propagates under the ſurface as that doth; from which ariſe many round, taper, herbaceous ſtalks, garniſhed with oblong ſmooth leaves, embracing the ſtalks like thoſe of a Reed; theſe ſtalks riſe near two feet high; out of the center, the club, or head of flowers is produced, which is near two inches long, the thickneſs of a man's finger, and blunt at the top, compoſed of ſeveral leafy ſcales, out of which the flowers come; theſe have but one thin white petal, which is of ſhort duration, ſeldom continuing longer than one day before it fades, and is never ſucceeded by ſeeds in this country. The time of its flowering is very uncertain, for ſometimes it flowers late in the winter, and at other times it has flowered in ſummer, ſo is not conſtant to any ſeaſon in England. It grows naturally in moſt parts of India.

This is propagated by parting of the roots; the beſt time for doing this is in the ſpring, before the roots put out new ſtalks. The roots muſt not be divided too ſmall, becauſe that will prevent their flowering. They ſhould be planted in pots, filled with light kitchen-garden earth, and plunged into the tan-bed in the ſtove, where they ſhould conſtantly remain, and may be treated in the ſame manner as the Ginger, which is fully treated of under the article Amomum.

The roots of this plant were formerly imported from India, and were much uſed in medicine; but of late years they have not been regarded, the roots of Ginger being generally ſubſtituted for theſe.

COTINUS. See Rhus.

COTONEA MALUS. See Cydonia.

COTONEASTER. See Mespilus.

COTULA. Lin. Gen. Plant. 868. Annathocyclus. Vaill. Act. Reg. Scien. 1719. Mayweed.

The Characters are,

It hath a flower compoſed of hermaphrodite florets in the diſk, and female half florets which form the rays; theſe are included in one common convex empalement, divided into ſeveral oval parts. The hermaphrodite florets are tubular, and cut into four unequal ſegments at the top; theſe have four ſmall ſtamina, terminated by tubular ſummits, and have two obtuſe ſtigmas, having one ſmall, oval, angular ſeed to each. The female half florets have an oval compreſſed germen, ſupporting a ſlender ſtyle, crowned by two ſtigmas, but have no ſtamina; theſe are ſucceeded by ſingle heart-ſhaped ſeeds, plain on one ſide, and convex on the other, with an obtuſe border.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia ſuperflua; the plants of this ſection have hermaphrodite and female flowers, which are fruitful.

The Species are,

1. Cotula (*Anthemoides*) foliis pinnato-multifidis, corollis radio deſtitutis. Hort. Cliff. 417. *Mayweed with many pointed winged leaves, and no rays to the flower.* Chamæmelum luteum capite aphyllo. C. B. P. 135.
2. Cotula (*Turbinata*) receptaculis ſubtus inflatis, turbinatis. Hort. Cliff. 417. *Mayweed whoſe receptacles are ſwollen and turbinated beneath.* Cotula Africana calice eleganter cæſio. Tourn. Inſt. R. H. 495.
3. Cotula (*Coronopi folia*) foliis lanceolato-linearibus, amplexicaulibus pinnatifidis. Hort. Cliff. 417. *Mayweed with narrow ſpear-ſhaped leaves embracing the ſtalk, having many points.* Chryſanthemum exoticum minus, capite aphyllo, Chamæmeli nudi facie. Breyn. Cent. 156.

The firſt ſort grows naturally in Spain, Italy, and the Archipelago; this is an annual plant, which riſes with a branching ſtalk half a foot high, garniſhed with leaves which are finely divided like thoſe of Chamomile. The flowers are produced ſingly at the end of the branches, which are very like thoſe of the naked Chamomile, but the heads riſe higher in the middle like a pyramid. This flowers in May and June, and the ſeeds ripen in Auguſt. If the ſeeds of this ſort are permitted to ſcatter, the plants will come up in the ſpring, and require no other care but to keep them clean from weeds, and thin the plants where they are too cloſe.

The ſecond ſort grows naturally at the Cape of Good Hope, from whence I have received the ſeeds; this is an annual plant, ſending out many branching ſtalks from the root, which ſpread on the ground, and are garniſhed with very fine divided leaves, covered with a lanugo, or cotton. The flowers are produced ſingly upon long foot-ſtalks, ariſing from the ſide of the branches; theſe have a narrow border of white rays, with a pale yellow diſk. It flowers in June and July, and the ſeeds ripen in autumn. This ſort muſt be raiſed on a moderate hot-bed in the ſpring, and when the plants have obtained ſtrength, they may be tranſplanted into a warm border, where they will ripen their ſeeds very well.

The third ſort is an annual plant, which ſends out trailing ſtalks about ſix inches long, garniſhed with ſucculent leaves, in ſhape like thoſe of Buckſhorn Plantain. The flowers grow from the diviſions of the ſtalks upon ſhort weak foot-ſtalks, being deſtitute of rays; they are of a ſulphur colour, and appear about the ſame time with the former. If the ſeeds of this ſort are ſown on a warm border where the plants are to remain, they will require no other culture but to keep them clean from weeds. The flowers of the two laſt ſorts ſtand erect, when they firſt appear, but ſo ſoon as the florets are impregnated, and their colour changes, the foot-ſtalks become very flaccid toward the top, and the flowers hang downward; but when the ſeeds are ripe, the foot-ſtalks become ſtiff, and the heads ſtand erect for the winds to diſperſe the ſeeds.

COTYLEDON. Lin. Gen. Plant. 512. Tourn. Inſt. R. H. 90. tab. 19. [Κοτυληδῶν, *Gr.* of Κοτυλη, *Gr.* a cavity; becauſe the leaves of this are hollowed like the navel, or becauſe it reſembles a veſſel wherewith the ancients uſed to draw water.] Navelwort.

The CHARACTERS are,

The flower hath a ſmall empalement of one leaf, divided into five parts at the top. It hath one funnel-ſhaped petal, cut into five parts at the brim, which turn backward. It hath five germina, which have each a ſquamous concave nectarium at their baſe, and each ſuſtains a ſtyle, crowned by a ſingle ſtigma; theſe are attended by ten erect ſtamina, which are terminated by erect ſummits, having four furrows. The germen afterward become ſo many oblong ſwelling capſules, opening longitudinally, with one valve, filled with ſmall ſeeds.

This genus of plants is ranged in the fourth ſection of Linnæus's tenth claſs, intitled Decandria Pentagynia, the flower having ten ſtamina and five ſtyles.

The SPECIES are,

1. COTYLEDON (*Umbilicus*) foliis cuculato-peltatis, ſerrato-dentatis, alternis, caule ramoſo, floribus erectis. Lin. Sp. Plant. 429. *Navelwort with hooded leaves ſharply indented, growing alternate, and a branching ſtalk with erect flowers.* Cotyledon major. *Greater Navelwort.* Umbilicus Veneris. Cluſ. H.
2. COTYLEDON (*Spinoſo*) foliis oblongis ſpinoſo-mucronatis, caule ſpicato. Lin. Sp. Plant. 429. *Navelwort with oblong pointed leaves, ending with a ſpine, and a ſpiked ſtalk.*
3. COTYLEDON (*Serrata*) foliis ovalibus, crenatis, caule ſpicato. Lin. Sp. Plant. 429. *Navelwort with oval crenated leaves and a ſpiked ſtalk.* Cotyledon Cretica, folio oblongo, fimbriato. Hort. Elth. 113. tab. 95. *Navelwort of Crete, with an oblong fringed leaf.*
4. COTYLEDON (*Hemiſpherica*) foliis ſemigloboſis. Hort. Cliff. 176. *Navelwort with ſemiglobular leaves.* Cotyledon Capenſis, folio ſemiglobato. Hort. Elth. 112. tab. 94.
5. COTYLEDON (*Orbiculata*) foliis ſubrotundis, planis integerrimis. Hort. Cliff. 276. *Navelwort with roundiſh, plain, entire leaves.* Sedum Africanum fruteſcens, incanum, orbiculatis foliis. H. L. 349.
6. COTYLEDON (*Ramoſiſſimo*) caule ramoſiſſimo, foliis rotundis, planis, marginibus purpureis. *Navelwort with a very branching ſtalk, and round, plain, hairy leaves, with purple edges.*
7. COTYLEDON (*Arboreſcens*) caule ramoſo, ſucculento, foliis obverſe ovatis, emarginatis, marginibus purpureis. *Navelwort with a branching ſucculent ſtalk, and obverſe oval leaves, which are indented at the top, and have purple borders.* Cotyledon major, arboreſcens Afra, foliis orbiculatis, glaucus, limbo purpureo, & maculis viridibus ornatis. Boerh. Ind. alt. 1. p. 287.
8. COTYLEDON (*Ovata*) caule ramoſo, ſucculento, foliis ovatis, planis, acuminatis oppoſitis ſemiamplexicaulibus. *Navelwort with a ſucculent branching ſtalk, and oval, plain, pointed leaves growing oppoſite, which half embrace the ſtalk.*
9. COTYLEDON (*Spuria*) foliis alternis ſpatulatis carnoſis integerrimis. Lin. Sp. 614. *Navelwort with ſpatule-ſhaped leaves.* Cotyledon Africana fruteſcens, folio longo & anguſto, flore flaveſcente. Com. Rar. Plant. 23. tab. 23.
10. COTYLEDON (*Laciniata*) foliis laciniatis, floribus quadrifidis. Hort. Cliff. 175. *Navelwort with cut leaves, and four-pointed flowers.* Cotyledon Afra, folio craſſo lato laciniato, floſculo aureo. Boerh. Ind. alt. 288.

The firſt ſort, which is that uſed in medicine, grows upon old walls and buildings in divers parts of England, particularly in Shropſhire and Somerſetſhire; in both which counties it greatly abounds upon old buildings, and on rocky places, but is not often found wild near London, nor often cultivated in gardens. This hath many round ſucculent leaves, whoſe foot-ſtalks are placed almoſt in the center, ſo as to reſemble a target. They are alternately ſawed on their edges, which frequently turn inward; the upper ſurface of the leaves are hollow in the middle, where the foot-ſtalks are joined on the lower ſide, ſo as to reſemble a navel, from whence the plant was titled Navelwort. From between the leaves ariſe the foot-ſtalks of the flowers, which in ſome places grow near three feet high, and in others not more than ſix inches, their lower part being garniſhed with leaves, and their upper part with flowers, which ſtand cloſe to the ſide of the branches, and grow erect; they are of a whitiſh yellow colour, and appear in June. It requires a dry rubbiſhy ſoil, and to have a ſhady poſition. This is a biennial plant, ſo that after it has perfected ſeed, the plant decays; but if the ſeeds are ſcattered on walls and old buildings as ſoon as it is ripe, or if the ſeeds are permitted to fall upon ſuch places, the plants will come up, and thrive much better than when they are ſown in the ground; and when once the plants are eſtabliſhed upon an old wall or building, they will ſow their ſeeds, and maintain their place better than when cultivated with more care.

The ſecond ſort grows naturally in Siberia, from whence it was brought to the imperial garden at Peterſburgh. This was ſent me by Dr. Amman, the late profeſſor of botany in that garden. It is a low plant, in ſhape like the Houſleek, but the leaves are longer, and terminate in ſoft ſpines. The flower-ſtalks riſe about four inches high, and ſupport four or five whitiſh flowers, which are cut at the brim into five parts. Theſe appear in April, and are ſometimes ſucceeded by ſeeds in England. This ſort requires a very ſhady ſituation, for if it is expoſed to the ſun in ſummer, the plants will ſoon decay. It is propagated by offſets like the Houſleek, and requires a pretty ſtrong ſoil.

The third ſort grows naturally in the Levant. This hath a fibrous root, from which is produced a ſingle upright ſucculent ſtalk, garniſhed with oblong, thick, ſucculent leaves, placed alternate, which are ſawed on their edges. The upper part of the ſtalk is garniſhed with purpliſh flowers, growing in a looſe ſpike, two or three being joined on the ſame foot-ſtalk, which is very ſhort. The flowers appear in June, and the ſeeds ripen in autumn. It is a biennial plant, which decays ſoon after the ſeeds are ripe. If this ſort is ſown upon a wall, it will thrive better than in the ground, and be leſs liable to ſuffer by froſt; ſo that where the ſeeds ſcatter themſelves in ſuch ſituations, the plants thrive better than when they are cultivated.

The fourth ſort grows naturally at the Cape of Good Hope. This hath a thick ſucculent ſtalk, which rarely riſes above a ſpan high, dividing into many branches, garniſhed with ſhort, thick, ſucculent leaves, which are very convex on their under ſide, but plain on their upper, not more than half an inch long, and a quarter broad, of a grayiſh colour ſpotted over with ſmall green ſpots, and ſit cloſe to the branches: the foot-ſtalks of the flower riſe from the top of the branches, and are ſix inches long, naked, and ſupport five or ſix flowers, which come out alternate from the ſide, ſitting very cloſe to the ſtalks; they are tubular, and cut into five parts at the top; theſe are greeniſh, with purple tips. It flowers in June and July, but never produces ſeeds in England.

The fifth ſort grows naturally upon dry gravelly ſpots at the Cape of Good Hope. It hath a thick ſucculent ſtalk, which by age becomes ligneous, and riſes three or four feet high, ſending out crooked branches, which grow irregular, garniſhed with thick, fleſhy, ſucculent leaves about two inches long, and near as wide toward the top; they are narrow at their baſe, and rounded at the top, of a ſea-green colour, with a purple edge, which is frequently irregularly indented. The flowers grow upon thick ſucculent foot-ſtalks, which ariſe from the end of the branches, and are near a foot long, naked, and ſupporting eight or ten flowers, growing in an irregular umbel at the top; theſe are of a pale yellow colour, having long tubes, which hang downward, cut into five parts at the brim, which turn backward, the ſtamina and ſtyle being longer than the tube of the flower, hanging downward. This ſort flowers in July, Auguſt, and September, but doth not ripen ſeeds in England.

The ſixth ſort is alſo a native of the Cape of Good Hope. This hath a ſhort, thick, ſucculent ſtalk, which rarely riſes more than a foot high, branching out on every ſide, ſo as to ſpread over the pots in which they are planted: they become woody by age, and are cloſely garniſhed with thick round leaves, of a grayiſh colour, with purple borders, plain on their upper ſide, but convex on their under, and very fleſhy, of an herbaceous colour within, and full of moiſture. This ſort hath not flowered in England, ſo far as I can learn, for I have kept plants of it which were twenty years old, but never attempted to flower. It is undoubtedly a different ſort from the former, although they have been ſuppoſed to be the ſame by ſome writers.

The ſeventh ſort is ſomewhat like the ſixth, but the ſtalks riſe higher, the leaves are much larger, and ſhaped more like thoſe of the fifth, but are ſpotted on their upper ſide with great numbers of dark green ſpots; they have a deep border of purple on their edges, and ſit cloſe to the branches. This hath not as yet flowered in England. This is alſo a native of Æthiopia.

The eighth ſort hath been of late years introduced into the gardens in Holland, from the Cape of Good Hope, where it grows naturally, and was ſent me by Dr. Adrian Van Royen, late profeſſor of botany at Leyden. This riſes with a ſucculent ſtalk near three feet high, which divides into many branches, growing erect, garniſhed with oval ſucculent leaves, placed oppoſite; they are of a lively green, and end in points, and half embrace the ſtalks with their baſe. This ſort hath not as yet produced any flowers in England.

The ninth ſort grows on rocky places at the Cape of Good Hope, from whence it was firſt brought to the gardens in Holland, and hath ſince been ſpread into moſt parts of Europe, where there are curious perſons who preſerve exotic plants in their gardens: this hath a ſhort, greeniſh, ſucculent ſtalk, which ſeldom riſes more than a ſpan high, dividing into ſeveral irregular branches, garniſhed with thick ſucculent leaves four inches long, and half an inch broad, and as much in thickneſs, having a broad concave furrow on their upper ſide, running almoſt their whole length, and are convex on their under ſide, of a bright green, with a purple tip. The foot-ſtalks of the flowers are produced at the end of the branches, and riſe near a foot high, having here and there an oblong pointed leaf, growing on their ſide. The flowers ſtand upon ſhort foot-ſtalks, which branch out from the principal ſtem; theſe are yellow, having pretty long tubes, which are cut at the top into five parts, and are reflexed backward. The flowers of this ſort hang downward, and the ſtamina are longer than the tube of the flower; the reflexed parts of the petal are tipped with purple. Dr. Linnæus has ſuppoſed this to be the ſame with the fifth ſort, but whoever has ſeen both plants, cannot doubt of their being diſtinct ſpecies.

The tenth ſort grows naturally in the warm parts of Africa, ſo is much more tender than either of the other ſorts: this riſes with an upright ſtem about a foot high, which is jointed and ſucculent, garniſhed with broad leaves, which are deeply cut on their edges; they are of a grayiſh colour, placed oppoſite, and almoſt embrace the ſtalks with their baſe. The foot-ſtalks of the flowers ariſe from the end of the branches, which are about ſix inches long, ſuſtaining ſeven or eight ſmall flowers of a deep yellow colour, which are divided into four parts almoſt to the bottom. The ſtamina of theſe flowers are not longer than the ſhort tube. This flowers at different ſeaſons of the year, but never produces any ſeeds in England. This ſort requires a warm ſtove to preſerve it through the winter in England, nor ſhould it be expoſed abroad in ſummer; for if it receives much wet, the ſtalks are very ſubject to rot; ſo that it ſhould conſtantly remain either in the ſtoves, or in ſummer ſhould be placed in an airy glaſs-caſe with other tender ſucculent plants, where they may have free air in warm weather, and be ſcreened from cold and wet; but in autumn they muſt be removed into the ſtove, where they ſhould be kept in a moderate temperature of warmth: this is propagated by cuttings, which ſhould be taken off in ſummer, and planted into ſmall pots, and plunged into a moderate hot-bed, and when they have taken root, they ſhould be removed into the ſtove. This plant muſt have but little water, eſpecially in winter.

The African kinds are all of them propagated by planting cuttings in any of the ſummer months, which ſhould be laid in a dry place for a fortnight or three weeks after they are taken from the plant, before they are planted; for theſe abound with juice through every part of the plant, which will certainly rot the cuttings, if they are not ſuffered to lie out of the ground, that the wounded part may heal over, and the great redundancy of ſap evaporate. The ſoil in which theſe plants thrive beſt, is one third freſh light earth from a paſture, one third ſand, and the other third part lime-rubbiſh and rotten tan, in equal quantities; theſe ſhould be well mixed, and laid in a heap ſix or eight months before it is uſed, turning it over five or ſix times, that the parts may the better incorporate; and before it is uſed, it will be proper to paſs it through a ſcreen, to ſeparate the large ſtones, clods, &c. therefrom.

Having prepared the earth, and your cuttings being in a fit order for planting, you muſt fill as many halfpenny pots with earth as you have cuttings to plant; then put one cutting in the middle of each pot about two or three inches deep or more, according to their ſtrength; then give them a little water to ſettle the earth cloſe about them, and ſet the pots in a warm ſhady place for about a week, to prepare the cuttings for putting forth roots; after which they ſhould be plunged into a moderate hot-bed of tanners bark, which will greatly facilitate their rooting; but obſerve to give them air, by raiſing the glaſſes at all times when the weather will permit, as alſo to ſhade the glaſſes in the heat of the day.

In about ſix weeks or two months time after planting, theſe cuttings will be rooted, when you muſt begin to expoſe them to the open air by degrees, firſt drawing the pots out of the tan, and ſetting them on the top, then raiſe the glaſſes very high in the daytime; and in about a week after remove the pots into a green-houſe, and there harden them for another week; after which they may be expoſed to the open air in a well defended place, obſerving not to ſet them into a place too much expoſed to the ſun, until they have been inured to the open air for ſome time.

In this place the plants may remain until the beginning of October, at which time you ſhould remove them into the conſervatory, placing them as near the windows as poſſible at firſt, letting them have as much free open air as the ſeaſon will permit, by keeping the windows open whenever the weather is good; and now you muſt begin to abate your waterings, giving it to them ſparingly; but you ſhould not ſuffer their leaves to ſhrink for want of moiſture, which is another extreme ſome people run into for want of a little obſervation; for when they are ſuffered to ſhrink for want of ſufficient moiſture to keep their veſſels diſtended, they are rendered incapable of diſcharging this moiſture whenever they receive it again. The tenth ſort ſhould be placed in a moderate ſtove in winter, nor muſt it be ſet abroad till Midſummer, for it is much tenderer than any of the others.

The beſt method to treat moſt of theſe plants is, to place them in an open, airy, dry glaſs-caſe, among Ficoideſſes and African Houſleeks, where they may enjoy as much of the ſun-ſhine as poſſible, and have a free, dry, open air; for if theſe are placed in a common green-houſe among ſhrubby plants, which perſpire freely, it will fill the houſe with a damp air, which theſe ſucculent plants are apt to imbibe; and thereby becoming too replete with moiſture, often caſt their leaves, and many times their branches alſo decay, and the whole plant periſhes.

COWSLIP. See Primula.

CRAB-TREE. See Malus.

CRAMBE. Lin. Gen. Plant. 739. Tourn. Inſt. R. H. 211. tab. 100. [Κραμϐὴ, *Gr.*] Sea Cabbage.

The Characters are,

The empalement of the flower is compoſed of four oval concave leaves which ſpread open. The flower hath four petals, placed in form of a croſs, which are large, oblong, and ſpread open; it hath ſix ſtamina, two of which are the length of the empalement, the other four are longer, and bifid at their points; theſe are terminated by ſingle ſummits, which branch into threads on their outſide. The petals have honey glands on their inſide, which are longer than the ſtamina. It hath an oblong germen, but no ſtyle, crowned by a thick ſtigma. The germen afterward becomes a round dry capſule, with one cell, incloſing one roundiſh ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, intitled Tetradynamia ſiliquoſa, the flower having four long and two ſhort ſtamina, and the ſeeds growing in pods.

The Species are,

1. Crambe (*Maritima*) foliis cauleque glabris. Fl. Suec. 570. *Sea Cabbage with ſmooth ſtalks and leaves.* Crambe maritima braſſicæ folio. Tourn. Inſt. 211.
2. Crambe (*Suecica*) foliis profundè laciniatis, caule erecto, ramoſo. *Sea Cabbage with leaves deeply cut, and an upright branching ſtalk.*
3. Crambe (*Orientalis*) foliis ſcabris, caule glabro. Lin. Sp. Plant. 671. *Sea Cabbage with rough leaves and a ſmooth ſtalk.* Crambe foliis & foliolis alternatim pinnatifidis. Prod. Leyd. 330.
4. Crambe (*Hiſpanica*) foliis cauleque ſcabris. Hort. Upſal. 193. *Sea Cabbage with rough ſtalks and leaves.* Rapiſtrum maximum rotundifolium monoſpermum. Corn. Canad. 147.

The firſt ſort ſends out many broad ſmooth leaves, which are deeply jagged on their ſides in obtuſe ſegments, and are of a grayiſh colour, ſpreading near the ground; between theſe ariſe a thick ſmooth foot-ſtalk about one foot high, which ſpreads out into many branches, which have at each joint one leaf of the ſame form as thoſe below, but much leſs; theſe foot-ſtalks ſubdivide again into many ſmaller, which are garniſhed with white flowers, growing in a looſe obtuſe ſpike, compoſed of four concave petals, placed in form of a croſs; theſe are ſucceeded by round dry ſeed-veſſels about the ſize of large Peaſe, having a ſingle ſeed in each. It flowers in June, and the ſeeds ripen in autumn. The roots of this ſort creep under ground, whereby it propagates very faſt.

The ſeeds of the ſecond ſort were ſent me from Peterſburgh for the firſt ſort, from which it differs greatly. This hath a perennial root, which ſends out ſeveral oblong, ſmooth, pointed leaves, irregularly cut on their ſides into acute ſegments almoſt to the midrib; theſe are very ſmooth, and of a ſea-green colour: between theſe ariſe the ſtalk, which grows three feet high, garniſhed below by oblong pointed leaves, which are acutely indented on their edges. The ſtalks branch out into many ſmaller, and theſe ſubdivide again into leſs, which are garniſhed with looſe ſpikes of white flowers like thoſe of the firſt ſort, which are ſucceeded by ſeeds of the ſame form. This differs greatly from the firſt in the ſhape of its leaves, which are longer, ending in points, and the ſegments do the ſame; whereas thoſe of the other are blunt, and not half ſo deeply cut. The ſtalks riſe more than twice the height of the firſt, branch out more, and the branches grow more erect; and theſe differences are conſtant, where the plants of both ſorts grow in the ſame ſoil.

The third ſort grows naturally in the Eaſt. This hath a biennial root, from which ariſe many leaves in the ſpring, that are alternately divided to the midrib; and theſe diviſions are again alternately cut on their edges into many points, ſo that they have the appearance of winged leaves, and are of a grayiſh colour. The ſtalks riſe about two feet high, and divide into many branches, which are terminated by looſe panicles of ſmall white flowers, placed in form of a croſs, which are ſucceeded by ſmall round capſules, each containing a ſingle ſeed. This flowers in June, and the ſeeds ripen in autumn, ſoon after which the roots decay.

The fourth ſort is an annual plant, which grows naturally in Spain and Italy. This riſes with a very branching ſtalk near three feet high, garniſhed with roundiſh heart-ſhaped leaves, indented on their edges, ſtanding upon long foot-ſtalks; the branches ſubdivide into many ſlender ones, which end in long looſe ſpikes of ſmall white flowers, which are ſucceeded by ſmall, round, dry ſeed-veſſels, which contain a ſingle ſeed. The leaves and ſtalks of this ſort are rough. It flowers in June, and the ſeeds ripen in autumn.

The firſt ſpecies is found wild upon ſea-ſhores in divers parts of England, but particularly in Suſſex and Dorſetſhire in great plenty, where the inhabitants gather it in the ſpring to eat, preferring it to any of the Cabbage kind; as it generally grows upon the gravelly ſhore, where the tide overflows it, the inhabitants obſerve where the gravel is thruſt up by the ſhoots of this plant, and open the gravel, and cut the ſhoots before they come out, and are expoſed to the open air, whereby the ſhoots appear as if they were blanched; and when they are cut ſo young, they are very tender and ſweet; but if they are ſuffered to grow till they are green, they become tough and bitter.

This plant may be propagated in a garden, by ſowing the ſeed ſoon after it is ripe, in a ſandy or gravelly ſoil, where it will thrive exceedingly, and increaſe greatly by its creeping roots, which will ſoon overſpread a large ſpot of ground, if encouraged; but the heads will not be fit to cut until the plants have had one year's growth: and in order to have it good, the bed in which the plants grow, ſhould, at Michaelmas, be covered over with ſand or gravel about four or five inches thick, which will allow a proper depth for the ſhoots to be cut before they appear above ground; and if this is repeated every autumn, in the ſame manner as is practiſed in earthing of Aſparagus-beds, the plants will require no other culture. This may be cut for uſe in April and May, while it is young; but if the ſhoots are ſuffered to remain, they will produce fine regular heads of white flowers, which appear very handſome, and will perfect their ſeeds, by which they may be propagated.

The other ſorts are only preſerved in curious gardens of plants for variety, but are not of any uſe or beauty. The perennial ſorts may be propagated in the ſame manner as the firſt.

CRANE'S-BILL. See Geranium.

CRANIOLARIA. Lin. Gen. Plant. 670. Martynia. Houſt. Gen.

The Characters are,

The flower hath a permanent empalement, compoſed of four ſhort narrow leaves which ſpread open, with a large ſwollen head, which is cut longitudinally on the ſide. The flower hath one petal, which is unequal, having a very long narrow tube, whoſe brim is divided into two lips; the upper being roundiſh and entire, but the under is divided into three parts, the middle ſegment being the largeſt. It hath four ſtamina, two of which are the length of the tube, and two are ſhorter; theſe are terminated by ſingle ſummits; at the bottom of the tube is ſituated an oval germen, ſupporting a ſlender ſtyle, crowned by an obtuſe thick ſtigma. The germen afterward becomes an oval leathery fruit, pointed at both ends, opening with two valves, incloſing a depreſſed woody nut, pointed at both ends, and recurved, having two or three furrows, ſo as to reſemble a ſkull, opening in two parts.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, the flowers having two long and two ſhort ſtamina, and the ſeeds being included in a capſule.

The Species are,

1. **Craniolaria** (*Annua*) foliis cordatis, angulatis lobatis. Lin. Sp. Plant. 862. *Craniolaria with angular heart-ſhaped leaves.* Martynia annua, villoſa, & viſcoſa, aceris folio, flore albo, tubo longiſſimo. Houſt. MSS.
2. **Craniolaria** (*Fruticoſa*) foliis lanceolatis dentatis. Lin. Sp. Plant. 618. *Craniolaria with ſpear-ſhaped indented leaves.* Geſnera arboreſcens amplo flore fimbriato & maculoſo. Plum. Nov. Gen. 27.

The firſt ſort was diſcovered in the neighbourhood of Carthagena in New Spain, by the late Dr. William Houſtoun, who ſent the ſeeds to England. This is an annual plant, which riſes with a branching ſtalk about two feet high; the branches come out oppoſite, which are hairy and viſcous; the leaves alſo are placed oppoſite, upon very long foot-ſtalks; theſe are of different ſhapes, ſome of them are divided into five lobes, others into three, and ſome are almoſt heart-ſhaped, ending in acute points; they are hairy and clammy. The flowers are produced from the ſide, and alſo at the end of the branches, ſtanding on ſhort foot-ſtalks, having an inflated ſheath or cover, out of which the tube of the flower ariſes, which is ſeven or eight inches long, and very ſlender; but at the top is divided into two lips, the under being large, divided into three broad ſegments, the middle being larger than the other two; the upper lip is roundiſh and entire: the flowers are ſucceeded by oblong fruit, having a thick dry ſkin, which opens lengthways, incloſing a hard furrowed nut, with two recurved horns. This is an annual plant, whoſe ſeeds muſt be ſown on a hot-bed in the ſpring; and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, filled with light freſh earth, and plunged into a moderate hot-bed, carefully ſhading them from the ſun till they have taken new root; after which they ſhould have free air admitted to them in proportion to the warmth of the ſeaſon, to prevent their drawing up weak, and afterwards treated in the ſame manner as other tender exotic plants, being too tender to thrive in the open air in England; ſo that when they are grown too large to remain under the frames, they ſhould be removed into the bark-ſtove, and plunged into the tan-bed, where they will flower in July, and with good management they often perfect their ſeeds in autumn. But the ſeeds of this plant ſhould remain on till they drop, otherwiſe they will not grow, for the outer covers of theſe ſeeds ſplit open and drop off like thoſe of the Almond, before the ſeeds are fully ripened.

The ſecond ſort grows naturally at the Havannah, and in ſome of the other iſlands in America. This riſes with a ſhrubby ſtalk to the height of ten or twelve feet, dividing upward into a few branches, which are garniſhed with ſpear-ſhaped leaves, cut on their edges; theſe are ſoft and hairy. The flowers are produced from the ſide of the branches, growing ſeveral together on the ſame foot-ſtalk; they are ſhaped like thoſe of the Foxglove, of a greeniſh yellow colour, with brown ſpots on the inſide; the flowers have a ſwelling tube, which is recurved, and the brim is ſlightly divided into five unequal ſegments. Theſe appear in July, but are not ſucceeded by ſeeds in England.

This ſort is propagated by ſeeds, which muſt be procured from the countries where it grows naturally, and ſhould be ſown on a hot-bed in the ſpring; when the plants are fit to remove, they ſhould be each planted into a ſeparate ſmall pot, filled with light kitchen-garden earth, and plunged into a freſh hot-bed, where they muſt be ſhaded from the ſun till they have taken freſh root; then they muſt have air admitted to them, according to the warmth of the ſeaſon, and frequently watered during the heat of ſummer. In autumn they muſt be removed into the bark-ſtove, and plunged into the tan-bed. During the winter ſeaſon, the plants ſhould not have much water, and may be treated in the ſame manner as other tender plants from thoſe countries. The plants ſeldom flower in England till the third year; and as they do not produce ſeeds here, it is with difficulty the ſort is preſerved in the European gardens, as there is no other method of propagating the plants but by ſeeds.

CRASSULA. Dillen. Hort. Elth. 114. Lin. Gen. Plant. 352. Leſſer Orpine, or Live-ever. This name was formerly applied to the Anacampſeros, or Orpine.

The Characters are,

The flower hath a five-leaved empalement. The corolla conſiſts of five narrow petals, which are joined at their baſe, are reflexed, and ſpread open at the brim. In the bottom of the tube are ſituated five nectarii, and there are five ſtamina ſituated round theſe, which ariſe from the bottom of the tube, and extend to the brim. At the bottom of the tube are placed five oblong pointed germina; after the flower is paſt, theſe become five capſules, opening lengthways, and filled with ſmall ſeeds.

This genus of plants is by Dr. Linnæus ranged in his fifth claſs of plants, and in the fifth diviſion, intitled Pentandria Pentagynia, which includes thoſe plants whoſe flowers have five ſtamina and five ſtyles.

The Species are,

1. **Crassula** (*Coccinea*) foliis planis cartilagineo-ciliatis, baſi connato vaginantibus. Vir. Cliff. 26. *Leſſer Orpine with plain leaves, having ſtiff edges ſet with ſilver hairs, and their baſe ſurrounding the ſtalk like ſheaths.* Cotyledon Africana fruteſcens, flore umbellato Coccineo. Com. Rar. 24.
2. **Crassula** (*Perfoliata*) foliis lanceolato-ſubulatis ſeſſilibus connatis, canaliculatis, ſubtus convexis. Hort. Cliff. 116. *Leſſer Orpine with ſpear-ſhaped awl-faſhioned leaves, ſurrounding the ſtalks with their baſe, channelled on their upper ſide, and convex on their under.* Craſſula altiſſima perfoliata. Dill. Hort. Elth. 114.
3. **Crassula** (*Cultrata*) foliis oppoſitis, obtuſè ovatis, integerrimis, hinc anguſtioribus. Hort. Cliff. 496. *Leſſer Orpine with oval blunt leaves placed oppoſite, which are entire, and narrow at their baſe.* Craſſula Anacampſerotis folio. Hort. Elth. 115. tab. 65.
4. **Crassula** (*Ciliata*) foliis oppoſitis, ovalibus, planiuſculis, diſtinctis, ciliatis, corymbis terminalibus. Hort. Cliff. 496. *Leſſer Orpine with oblong plain leaves placed oppoſite, which are bordered with ſilver hairs, and ſtalks terminated by a corymbus of flowers.* Craſſula cauleſcens, foliis ſempervivi cruciatis. Hort. Elth. 116. tab. 98.
5. **Crassula** (*Scabra*) foliis oppoſitis, patentibus, connatis ſcabris ciliatis, corymbis terminalibus. Lin. Sp. Plant. 283. *Leſſer Orpine with rough ſpreading leaves growing oppoſite.* Cotyledon Africana fruteſcens, foliis aſperis, anguſtis, acuminatis, flore vireſcente. Mart. Cent. 24.
6. **Crassula** (*Nudicaulis*) foliis ſubulatis, radicatis, caule nudo. Hort. Cliff. 116. *Leſſer Orpine with awl-ſhaped leaves which put out roots, and a naked ſtalk.* Craſſula Cæſpitoſa longifolia. Hort. Elth. 116. tab. 98.
7. **Crassula** (*Punctata*) caule flaccido, foliis connatis, cordatis, ſucculentis, floribus confertis terminalibus. *Leſſer Orpine with a weak ſtalk growing through the leaves, which are heart-ſhaped and ſucculent, and flowers growing in cluſters at the end of the branches.*
8. **Crassula** (*Fruticoſa*) foliis longis, teretibus, alternis, caule fruticoſo, ramoſo. *Leſſer Orpine with long taper leaves placed alternate, and a branching ſhrubby ſtalk.*
9. **Crassula** (*Sediodes*) caule flaccido, prolifero, determinatè-folioſo, foliis patentiſſimis, imbricatis. Hort. Cliff. 496. *Leſſer Orpine with a proliferous weak ſtalk, which is leafy, and leaves placed in the manner of tiles, and ſpreading open.* Sedum Afrum, ſaxatile, foliis ſedi vulgaris, in roſam verè compoſitis. Boerh. Ind. alt. 1. 287.
10. **Crassula** (*Pelucida*) caule flaccido repente, foliis oppoſitis. Lin. Sp. Plant. 283. *Leſſer Orpine with a weak creeping ſtalk, leaves placed oppoſite, and a ſhrubby ſucculent ſtalk.* Craſſula portulacæ facie repens. Hort. Elth. 119.

11. **Crassula** (*Portulacaria*) foliis obovatis, oppoſitis, caule arboreo. Lin. Sp. 406. *Leſſer Orpine with obverſe oval leaves placed oppoſite, and a tree-like ſtalk.* Craſſula portulacæ facie arboreſcens. Hort. Elth. 120. tab. 90.

The firſt ſort hath a round reddiſh ſtalk, which is jointed, riſing about three feet high, which divides upward into many irregular branches, garniſhed with oblong plain leaves placed oppoſite, having a griſtly border, ſet with ſmall ſilver hairs, and cloſely embrace the ſtalks with their baſe. The flowers are produced at the end of the branches in cloſe umbels, ſitting very cloſe to the end of the branches; theſe are funnel-ſhaped, having pretty long tubes cut at the top into five parts, which ſpread open; they are of a fine ſcarlet colour, and ſtand erect; the uſual time of their flowering is July or Auguſt. This is propagated by cuttings during any of the ſummer months; theſe ſhould be cut off about a fortnight before they are planted, and laid in a dry place that the wounded part may heal over; then they ſhould be each planted in a ſmall pot filled with light ſandy earth, and plunged into a moderate hot-bed, giving them but little water. In about ſix weeks theſe will have put out roots and begin to grow, when they ſhould have a large ſhare of air admitted to them, and muſt be gradually inured to bear the open air, into which they ſhould be removed, placing them in a ſheltered ſituation, where they may remain till autumn; when they muſt be removed into a dry airy glaſs-caſe, where they may enjoy the ſun as much as poſſible, and be ſcreened from the wet and cold. In warm dry weather, during the ſummer months while they are abroad, theſe plants ſhould be gently watered two or three times a week; but in winter they ſhould have very little water, leſt it rot their ſtems. Theſe plants require no artificial heat in winter, but they muſt be ſecured from froſt and wet.

The ſecond ſort will riſe with an upright ſtalk ten or twelve feet high, if it is not broken or injured, but it requires ſupport; for the ſtalks being ſlender, and the leaves very weighty, they are very ſubject to break, eſpecially if they are expoſed to the wind. The leaves of this plant are about three inches long; they are hollowed on the upper ſide, and have a convex ridge on their lower, and are placed oppoſite, ſurrounding the ſtalks with their baſe; theſe alternately croſs each other; they are very thick, ſucculent, and of a pale green colour, ending in acute points; at the top of the ſtalk the flowers are produced in large cluſters; they are of a whitiſh herbaceous colour, having ſhort tubes, which are cut into five parts at the brim, ſpreading open. The ſtalk which ſuſtains the flowers is pretty thick and ſucculent, generally turning firſt downward, and then upward again, almoſt in the form of a ſyphon. It flowers in July, but doth not produce ſeeds here. This ſort is propagated by cuttings in the ſame manner as the firſt, and the plants require the ſame treatment.

The third ſort riſes with a weak ſucculent ſtalk about two feet high, ſending out many irregular branches, garniſhed with oblong, oval, thick leaves, plain on their upper ſide, but convex below, of a deep green; their borders are ſet with a few ſilvery hairs. The ſtalk which ſupports the flowers riſes from the top of the branches, and is from four to ſix inches long, putting out ſeveral ſide branches, which grow erect; theſe are terminated by large cluſters of ſmall greeniſh flowers, which appear in June and July. This is propagated by cuttings in the ſame manner as the two former, but being pretty hardy, ſhould not be ſo tenderly treated; for if the cuttings of this are planted in a border of light earth, they will put out roots, and may afterward be taken up and potted, to be ſheltered in winter.

The fifth ſort hath a very weak ſucculent ſtalk, which riſes about a foot and a half high, dividing upward into ſmall branches, garniſhed with thin rough leaves which are flat, near two inches long, and a quarter broad at their baſe, gradually narrowing to a point; theſe are rough, placed oppoſite, and embrace the ſtalks with their baſe. The flowers come out in ſmall cluſters at the end of the branches; they are ſmall, and of an herbaceous colour, ſo make no figure; they appear in June and July. This may be propagated by cuttings, which may be treated in the ſame manner as the fourth ſort.

The ſixth ſort never riſes with a ſtalk, but the leaves come out cloſe to the ground, forming a ſort of head; they are taper, ſucculent, ending in points, and frequently put out roots; out of the center of theſe ariſe the flower-ſtalk, which grow about ſix inches high, branching into two or three ſhoots upward, each being terminated by cluſters of greeniſh flowers, which make no great appearance. It flowers in May, and ſometimes again in the latter part of ſummer. This is propagated by taking off the heads, or ſide offsets, which ſhould be laid to dry three or four days before they are planted; then they may be treated in the ſame manner as the other hardier ſorts beforementioned.

The ſeventh ſort hath been lately introduced to the gardens in Holland, from the Cape of Good Hope; it was ſent me by Dr. Adrian Van Royen, late profeſſor of botany at Leyden. This hath very ſlender ſtalks, which are full of joints, ſo trail upon the ground, unleſs they are ſupported, cloſely garniſhed with thick, ſucculent, heart-ſhaped leaves, placed oppoſite, which are cloſely joined at their baſe, ſo that the ſtalks run through them; they are of a grayiſh colour; the ſtalks are divided, and grow about eight or nine inches long, and are terminated by cluſters of ſmall white flowers, ſitting very cloſe to the top of the ſtalks; theſe appear in the ſpring, and alſo again in the latter part of ſummer. It is propagated by cuttings in the ſame manner as the other hardier ſorts, and may be treated in the ſame way.

The eighth ſort was ſent me from Leyden, by the gentleman before-mentioned; this riſes with a ſhrubby ſtalk four or five feet high, dividing into many branches, which at firſt are taper and ſucculent, but by age becomes ligneous; they are garniſhed with very ſlender, taper, ſucculent leaves, which are near three inches long, and are flaccid, generally turning downward, eſpecially in winter, when they are in the houſe; but as it hath not as yet flowered here, I can give no further deſcription of it. This is equally hardy with the former ſorts, and takes eaſily from cuttings, ſo may be treated in the ſame way as the former.

The ninth ſort is a low plant, with the appearance of Houſleek, having open ſpreading heads very like thoſe of ſome ſorts of Houſleek, which grow on the ends of very ſlender trailing ſtalks, which are produced in plenty on every ſide the parent plant, in like manner as the childing Marigold. The flower-ſtalks ariſe from the center of theſe heads, which are naked, about four inches long, and are terminated by cloſe cluſters of herbaceous flowers, which appear in different ſeaſons of the year. This plant propagates very faſt by the ſide heads, which come out from the parent plant, which frequently put out roots as they trail on the ground, ſo may be taken off and potted, during any of the ſummer months; this is equally hardy with the former ſorts, ſo the plants may be treated in the ſame way.

The tenth ſort hath very ſlender, trailing, ſucculent ſtalks, of a reddiſh colour, which put out roots at the joints as they lie upon the ground. The ſtalks and leaves of this ſort have the appearance of Purſlane, but trail upon the ground like Chickweed. The flowers are produced in ſmall cluſters at the end of the branches; theſe are white, with a bluſh of purple at their brim; they appear in ſummer at different times, and are often ſucceded by ſeeds, which grow eaſily. This ſort is eaſily propagated by its trailing branches, and the plants require the ſame treatment as the other hardy ſorts, but unleſs they are often renewed will decay.

The eleventh ſort riſes with a very thick, ſtrong, ſucculent ſtalk to the height of three or four feet, ſending out branches on every ſide, ſo as to form a kind of pyramid, the lower branches being extended to a great length, and the other diminiſhing gradually to the top; theſe are of a red or a purpliſh colour, and very ſucculent; they are garniſhed with roundiſh ſucculent leaves very like thoſe of Purſlane, from whence the gardeners have titled it the Purſlane-tree.

This ſort hath not flowered in England, though it has been many years in the gardens, ſo that we are not ſure if it is properly ranged in this genus; but from the outward appearance it ſeems to be nearly allied to ſome of the other ſpecies, on which account Dr. Dillenius has placed it here.

It is propagated with great facility by cuttings, which may be planted during any of the ſummer months; but theſe ſhould be laid to dry for ſome days before they are planted, that the wounded part may be healed over, otherwiſe they will rot. This ſort is ſomewhat tenderer than the four ſorts laſt mentioned, ſo muſt be placed in a warm glaſs-caſe in winter, where it may enjoy the full ſun, and ſhould have very little water during that ſeaſon. In ſummer the plants ſhould be placed abroad in a ſheltered ſituation, and in warm weather will require to be refreſhed with water twice a week; but as the ſtalks are very ſucculent, too much wet at any ſeaſon is very hurtful to theſe plants.

All the hardy ſorts of Craſſula may be treated in the ſame way as the Ficoides, and other hardier kinds of ſucculent plants, with this difference only, not to give them ſo much water; but the firſt, ſecond, and eleventh ſorts require to be placed in a warm dry glaſs-caſe in winter, and muſt not be ſo long expoſed abroad in the ſummer as the other ſpecies, nor ſhould have much water, eſpecially in the winter.

Theſe plants are preſerved in moſt curious gardens for the ſake of variety, which conſiſts more in the outward appearance of their plants, than in the beauty of their flowers, except the firſt ſort, whoſe flowers are of a beautiful ſcarlet, and grow in cloſe bunches at the end of the branches; ſo that when ſeveral of the branches are garniſhed with flowers at the ſame time, they make a fine appearance, and theſe flowers continue in beauty a long time; but the flowers of the other ſorts are ſmall, and moſt of them are of an herbaceous colour, ſo make no figure.

Dr. Dillenius, who firſt eſtabliſhed this genus, and ſeparated the ſpecies from Cotyledon, to which many of them had been joined by former botaniſts, made their difference to conſiſt in the ſhape of the flower; ſo that all the ſorts with long tubulous flowers of one leaf, he placed under the genus of Cotyledon, and thoſe whoſe flowers have five petals, he placed under this genus of Craſſula: but Dr. Linnæus makes their difference to conſiſt in the number of their ſtamina, ſo that all thoſe whoſe flowers have but five ſtamina, he ranges under the title of Craſſula, and thoſe which have ten ſtamina, he puts under that of Cotyledon; ſo that by his ſyſtem they are removed to a great diſtance from each other, and the firſt ſort here mentioned is brought from Cotyledon, with whoſe characters in every other reſpect it agrees, and is placed here.

CRATÆGUS. Tourn. Inſt. R. H. 633. Lin. Gen. Plant. 547. The Wild Service.

The Characters are,

The flower hath a permanent empalement of one leaf, cut into five concave ſegments, which ſpread open. It hath five roundiſh concave petals, which are inſerted into the empalement, and many ſtamina, terminated by roundiſh ſummits, which are alſo inſerted in the empalement. The germen is ſituated under the flower, ſupporting two ſlender ſtyles, crowned with roundiſh ſtigmas. The germen afterward becomes an oval or roundiſh umbilicated berry, incloſing two oblong hard ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's twelfth claſs, intitled Icoſandria Digynia, the flower having twenty or more ſtamina, which are inſerted to the empalement, and two ſtyles.

The Species are,

1. Cratægus (*Aria*) foliis ovatis inæqualiter ſerratis, ſubtus tomentoſis. Hort. Cliff. 187. *Wild Service with oval leaves unequally ſawed, and woolly on their under ſide.* Cratægus folio ſubrotundo, ſerrato, ſubtus incano. Tourn. Inſt. R. H. 633. Aria Theophraſti, and in ſome countries, *The White Beam, or white Leaf-tree.*
2. Cratægus (*Torminalis*) foliis cordatis ſeptangulis, lobis infimis divaricatis. Lin. Sp. Plant. 476. *Wild Service with heart-ſhaped leaves, having ſeven angles, whoſe lower lobes ſpread aſunder.* Cratægus folio laciniato. Tourn. Inſt. 633. *Wild, or Maple-leaved Service.*
3. Cratægus (*Alpina*) foliis oblongo-ovatis ſerratis, utrinque virentibus. *Wild Service with oblong, oval, ſawed leaves, which are green on both ſides.* Cratægus folio oblongo, ſerrato, utrinque virenti. Tourn. Inſt. 633.
4. Cratægus (*Coccinea*) foliis ovatis repando-angulatis ſerratis glabris. Hort. Cliff. 187. *Cratægus with oval, ſmooth, ſawed leaves, having angles.* Meſpilus ſpinoſa, ſc. oxyacantha Virginiana maxima. Tourn. Inſt. 633. *Commonly called Cockſpur Hawthorn.*
5. Cratægus (*Crus Galli*) foliis lanceolato ovatis ſerratis glabris, ramis ſpinoſis. Lin. Sp. 682. *Cratægus with oval, ſpear-ſhaped, ſawed leaves, and prickly branches.* Meſpilus aculeata pyrifolia denticulato ſplendens, fructu inſigni rutilo, Virginienſis. Pluk. Alm. 249. *Commonly called Virginian L'Azarole.*
6. Cratægus (*Lucida*) foliis lanceolatis ſerratis lucidus, ſpinis longiſſimis, floribus corymboſis. *Cratægus with lucid, ſpear-ſhaped, ſawed leaves, very long ſpines, and flowers in a corymbus.* Meſpilus prunifolius, ſpinis longiſſimis fortibus, fructu rubro magno. Flor. Virg. 55.
7. Cratægus (*Azarolus*) foliis obtuſis ſubtrifidis dentatis. Lin. Sp. 683. *Cratægus with obtuſe, trifid, indented leaves.* Meſpilus Apii folio laciniato. C. B. P. 453. *Commonly called L'Azarole.*
8. Cratægus (*Oxyacantha*) foliis obtuſis ſubtrifidis ſerratis. Hort. Cliff. 188. *Cratægus with obtuſe, trifid, ſawed leaves.* Meſpilus Apii folio, ſylveſtris ſpinoſa, ſc. oxycantha. C. B. P. 454. *The common White Thorn.*
9. Cratægus (*Tomentoſa*) foliis cuneiformi-ovatis ſerratis ſubangulatis ſubtus villoſis ramis ſpinoſis. Lin. Sp. 682. *Cratægus with oval, wedge-ſhaped, ſawed, angular leaves, hoary on their under ſide, and prickly branches.* Meſpilus Virginiana groſſulariæ foliis. Pluk. Phyt. 100. f. 1.

The firſt ſort grows naturally on the chalky hills in Kent, Surry, and Suſſex, and in ſome other parts of England, and riſes to the height of thirty or forty feet, with a large trunk, dividing upward into many branches; the young ſhoots have a brown bark, covered over with a mealy down, garniſhed with oval leaves between two and three inches long, and one and a half broad in the middle, of a light green on their upper ſide, but very white on their under, having many prominent tranſverſe veins, running from the midrib to the border, where they are unequally ſawed, ſome of the indentures being much deeper, and the ſegments broader than others. The flowers are produced at the ends of the branches in bunches, their foot-ſtalks being meally, as are alſo the empalements of the flowers, which are cut into five obtuſe ſegments, and are reflexed. The flowers have five ſhort petals, which ſpread open like thoſe of the Pear-tree, having a great number of ſtamina of the ſame length with the petals, terminated by oval ſummits. The germen, which is ſituated below the flowers, afterwards becomes an oval fruit, crowned with the empalement of the flower, having one cell, in which is incloſed three or four ſeeds. It flowers in May, and the fruit ripens in autumn.

This tree may be propagated by ſeeds, which ſhould be ſown ſoon after they are ripe; for if they are kept out of the ground till ſpring, they remain at leaſt one year in the ground before the plants appear; ſo that the fruit ſhould be buried in the ground, as is practiſed with the common Haws, Holly-berries, and thoſe other hard ſeeds which do not come up the ſame year; and when the plants come up, they may be treated in the ſame manner as the Haws, but they ſhould by no means be headed or cut down; when theſe plants are upon a poor chalky ſoil, they make great progreſs, and the wood is very white and hard, ſo has been often uſed for making cogs for mills, and many other purpoſes where hard tough timber is wanted.

It may alſo be propagated by layers in the ſame manner as the Lime-tree and Elm, but theſe ſhould be laid in the young wood; but they are two years before they have ſufficient roots to tranſplant. I have alſo raiſed a few plants from cuttings, which were planted in autumn, in a ſhady border, but there was not more than one eighth part of the cuttings which ſucceeded; therefore I would recommend the raiſing them from ſeeds, for the trees ſo raiſed grow much larger and ſtraiter than thoſe which are raiſed either from layers or cuttings.

The tree will take by grafting, or budding it upon Pear-ſtocks very well, and Pears will take by grafting upon theſe trees, ſo that there is a nearer affinity between the Cratægus and Pear, than there is between either of theſe and the Meſpilus; for although both theſe will ſometimes take upon the Meſpilus, yet neither of them thrive ſo well, or laſt ſo long, when grafted, or budded upon thoſe ſtocks, as they do upon each other; therefore Tournefort, who has joined the Cratægus in his ſection, with the Pear and Quince, has come nearer to the natural diviſion of their genera, than thoſe who have joined the Cratægus to the Meſpilus.

There is another ſpecies of this tree which grows naturally about Verona, from whence I have received dried ſamples of it, but they were without flower and fruit, and came over by the ſame title as the former; for as there is no other growing in that neighbourhood, they have ſuppoſed it to be the common ſort; but if that is the Aria of Theophraſtus, thoſe trees which grow in England are not, for the leaves of the ſort from Verona are ſpear-ſhaped, and above an inch long, and not ſo broad by an inch as thoſe of the Engliſh, and the nerves on the under ſide of the leaves are purpliſh, the leaves terminating in acute points, ſo that I make no doubt of its being a different ſpecies; but as I have not ſeen the growing tree, I would not enumerate it till I had been better informed.

The ſecond ſort grows naturally in many parts of England, and is chiefly found upon ſtrong ſoils; it formerly grew in great plenty in Cane-Wood, near Hampſtead; and lately there was ſome young trees growing in Biſhop's-Wood, near the ſame place; but in many parts of Hertfordſhire there are large trees now growing: this riſes to the height of forty or fifty feet, with a large trunk, ſpreading at the top into many branches, ſo as to form a large head. The young branches are covered with a purpliſh bark, marked with white ſpots, and are garniſhed with leaves placed alternately, ſtanding on pretty long foot-ſtalks; theſe are cut into many acute angles, like thoſe of the Maple-tree; they are near four inches long, and three broad in the middle, having ſeveral ſmaller indentures toward the top, of a bright green on their upper ſide, but a little woolly on their under. The flowers are produced in large bunches toward the end of the branches, they are white, and ſhaped like thoſe of the Pear-tree, but ſmaller, and ſtand upon longer foot-ſtalks; theſe appear in May, and are ſucceeded by roundiſh compreſſed fruit, which are ſhaped like large Haws, and ripen late in autumn, when they are brown; and if kept till they are ſoft, in the ſame way as Medlars, they have an agreeable acid flavour. The fruit of this tree is annually ſold in the London markets in autumn.

The wood of this tree is hard, and very white, and is very uſeful for many purpoſes; but particularly ſo to the millwrights. It may be propagated in the ſame way as the former ſort, but requires a ſtrong ſoil.

The third ſort grows naturally upon mount Baldus, from whence I received it, and on other mountainous parts of Italy; this riſes with a woody trunk about twenty feet high, dividing into many branches, which are covered with a purpliſh ſpotted bark, and cloſely garniſhed with oblong ſawed leaves, ſtanding alternate, on very ſhort foot-ſtalks; they are about three inches long, and one and a half broad, in the broadeſt part, leſſening toward both ends; they are ſlightly ſawed on their edges, and of a deep green on both ſides. The flowers are produced at the end of the branches in ſmall bunches, which have rarely more than four or five flowers in each; they are white, and much ſmaller than thoſe of the former ſorts; theſe are ſucceeded by fruit about the ſize of the common Haw, which is of a dark brown colour when ripe. It flowers in May, and the fruit ripens in autumn.

The fourth ſort is a native of North America, but has been many years cultivated in the Engliſh gardens, where it is known by the title of Cockſpur Haw. Of this there are two ſpecies, one of which has no ſpikes on the branches; but the other has ſtrong thorns which are curved downwards, greatly reſembling the ſpur of a cock, from whence it had this appellation: in other reſpects both ſorts agree in the form of their leaves, their flowers and fruit. However, Dr. Linnæus has been ill informed of the two ſorts by Kalm, who went to America, and is now profeſſor at Abo in Sweden; for the doctor has added the appellation of Cockſpur to the fifth ſort here mentioned, which has long been known in England by the title of Virginia L'Azarole.

The fourth ſort riſes to the height of near twenty feet in England, where the trunk becomes large, and divides into many ſtrong branches, ſo as to form a large head; the leaves are large, oval, and deeply ſawed on their edges, ſo as almoſt to divide them into lobes, which are placed without order; the flowers come out from the ſide of the branches in cluſters; they are large, compoſed for the moſt part of five petals, which ſpread open, and are ſucceeded by pretty large Pear-ſhaped fruit of a ſcarlet colour. It flowers in May, and the fruit ripens in September.

The fifth ſort is generally known by the title of Virginia L'Azarole; this riſes with a ſtrong ſtem to the height of fifteen feet or more, ſending out many irregular branches covered with a light brown bark, and have a few thorns on their ſides; the leaves have ſhort foot-ſtalks, they are narrow at their baſe, but widen upward ſo as to become almoſt of an oval figure, of a lucid green on their upper ſide, and pretty deeply ſawed on their edges; the flowers are white, pretty large, and compoſed of five petals which expand: theſe are ſucceeded by large fruit of a ſcarlet colour; it flowers the end of May, and the fruit ripens in September.

The ſixth ſort grows naturally in North America; this riſes with a ſtrong ſtem to the height of ten or twelve feet, ſending out many ſtrong irregular branches, which, while young, is covered with a bright brown bark, but that on the older branches is of a lighter colour; the leaves are oval, ſpear-ſhaped, ſlightly ſawed on their edges, of a bright green on their upper ſide, but paler on their under; ſometimes they are placed by pairs, at others three or four come out from the ſame joint; the flowers are produced in large cluſters toward the end of the branches, forming a ſort of corymbus, and are ſucceeded by roundiſh fruit of a middling ſize, and a deep red colour. As the branches of this ſort ſhoot very ſtrong, and are generally interwoven with each other, being armed with very long ſtrong thorns, it is very proper for outward fences round gardens or fields.

The ſeventh ſort grows naturally in Italy and the Levant, where the fruit is ſerved up to table with their deſert; this hath a ſtrong ſtem riſing twenty feet high, having many ſtrong irregular branches, covered with a light-coloured bark; the leaves are in ſhape ſomewhat like thoſe of the common Hawthorn, but they are much larger, have broader lobes, and are of a paler colour; the flowers come out in ſmall cluſters from the ſide of the branches, which are in ſhape like thoſe of the common Hawthorn, but are much larger; as is alſo the fruit, which when fully ripe has an agreeable acid taſte, for which it is eſteemed by the inhabitants of the countries where it grows naturally.

The eighth ſort is the common Hawthorn, which is generally planted for fences in moſt parts of England, therefore being univerſally known to the inhabitants, it requires no deſcription: there are two or three varieties of this ſort, which differ in the ſize of their leaves and the ſtrength of their ſhoots; however, thoſe with the ſmalleſt leaves are generally preferred for hedges, as their branches always grow cloſer together; the method of raiſing the plants, and planting them for hedges, being fully treated of under the article of Hedges, I need not repeat here.

The ninth ſort grows naturally in North America, this has a ſlender ſhrubby ſtalk, riſing about ſix or ſeven feet high, ſending out many irregular branches, armed with long ſlender thorns, and garniſhed with ſhort, oval, wedge-ſhaped leaves, which are ſawed on their edges, and are woolly on their under ſide; the flowers are ſmall, proceeding from the ſide of the branches, ſtanding ſometimes ſingle, and at other times two or three upon the ſame foot-ſtalk, having large leafy empalements, and are ſucceeded by ſmall roundiſh fruit, with a large leafy umbilicus, which was before the empalement of the flower: the flowers appear the beginning of June, and the fruit ripens very late in the autumn.

This ſort may be propagated in the ſame manner as the firſt, but requires a ſtrong deep ſoil, otherwiſe it will not thrive. It is very hardy in reſpect to cold, but at preſent is very rare in England.

All the ſorts of Haws may be propagated by ſeeds, which ſhould be ſown in autumn, in the ſame manner as hath been directed for the firſt ſort; but as theſe ſeeds are frequently brought from America, and do not arrive here till ſpring, the fruit may be buried in the ground till the autumn following, when they may be taken up and ſown in drills, being careful to cover them ſo as to prevent birds from deſtroying them. In the ſpring following the plants will come up, which ſhould be moderately watered two or three times a week, if the ſpring ſhould prove dry; during the ſummer, they muſt be kept clean from weeds, which if ſuffered to grow, will ſoon overbear the plants and deſtroy them. The following ſpring the plants ſhould be planted out before they begin to ſhoot, into a nurſery-bed, where they may grow two years to get ſtrength, when they may be tranſplanted where they are to remain. If theſe plants are planted in a moiſt light ſoil, their roots will extend to a conſiderable diſtance, and put up many ſhoots, which may be taken off in the ſpring, and thereby may be increaſed; this will alſo take if grafted on the Pear, and if the young branches are laid down, they will take root, ſo the plants may be propagated either way.

The other ſorts of Hawthorn are generally planted among flowering ſhrubs of the ſame growth, where they add to the variety.

CRATEVA. Lin. Gen. Plant. 528. Tapia. Plum. Nov. Gen. 22. tab. 21. Garlic Pear.

The Characters are,

The empalement of the flower is of one leaf, cut at the top into four oval ſegments, which ſpread open. The flower hath four oval petals, which are narrow at their baſe, and broad at the top. It hath many briſtly ſtamina, which are longer than the petals, terminated by oblong erect ſummits. It hath a long incurved ſtyle, upon which ſits the oval germen, crowned by the ſtigma, ſitting cloſe on the top. The germen afterward becomes a large fleſhy globular fruit with one cell, including many kidney-ſhaped ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's eleventh claſs, intitled Dodecandria Monogynia, the plants of this claſs and ſection have twelve ſtamina in their flowers, and one ſtyle.

The Species are,

1. Crateva (*Tapia*) inermis foliis integerrimis, foliolis lateralibus baſiantica brevioribus. Lin. Sp. 673. *Smooth Crateva, or Garlic Pear.* Tapia arborea triphylla. Plum. Nov. Gen. 22.
2. Crateva (*Marmalos*) ſpinoſa foliis ſerratis. Flor. Zeyl. 212. *Prickly Crateva.* Cucurbitifera trifolia ſpinoſa medica, fructu pulpa Cydonii æmula. Pluk. Alm. 125.

The firſt ſort grows naturally in both Indies. I received the fruit of this from Jamaica, where it grows in great plenty, which were ſent me by William Williams, Eſq; of St. Anne's, in that iſland, who has been ſo kind as to furniſh me with many other curious ſeeds which have ſucceeded in the Chelſea garden.

This tree hath a very large trunk, which riſes to the height of thirty feet or upward, covered with a dark green bark, ſending out many branches, ſo as to form a large head. The branches are garniſhed with trifoliate leaves, ſtanding on pretty long foot-ſtalks; the middle leaf, which is much larger than either of the other, is oval, about five inches long, and two and a half broad in the middle. The two ſide leaves are oblique, thoſe ſides which join the middle leaf being much narrower than the other, and turn at both ends toward the middle, ſo that their midrib is not parallel to the ſides; theſe two end in acute points. The leaves are ſmooth, of a light green on the upper ſide, but pale on their under; their edges are entire. The flowers are produced at the ends of the branches, ſtanding upon long foot-ſtalks; theſe have empalements of one leaf, which are cut into four ſegments, almoſt to the bottom. The flower hath four oblong petals, which ſpread open, and are reflexed, having many long ſlender ſtamina, which are connected at their baſe, but ſpread open above, and are terminated by oblong purple ſummits; theſe ſurround a ſlender long ſtyle, upon which is ſituated the oval germen, which is crowned by an obtuſe ſtigma. The germen afterward becomes a round fruit, about the ſize of an Orange, having a hard brown ſhell, or cover, incloſing a meally pulp, filled with kidney-ſhaped ſeeds. This fruit hath a ſtrong ſmell of Garlic, which is communicated to the animals that feed on it. This is propagated by ſeeds, which muſt be procured from the countries where the trees grow naturally, and muſt be ſown on a hot-bed in the ſpring; when the plants come up, they muſt be treated in the ſame manner as hath been directed for the Annona, to which article the reader is deſired to turn for the culture.

The ſecond ſort grows naturally in India, where it grows to a great height, with a large trunk, ſending out many long branches, garniſhed with trifoliate leaves, which are oblong, entire, and end in acute points; between theſe the branches are armed with long ſharp thorns, which come out by pairs, and ſpread aſunder. The flowers are produced in ſmall cluſters from the ſide of the branches, five or ſeven ſtanding upon a common branching foot-ſtalk; theſe have each five acute petals, which are reflexed, and many ſtamina which ſtand round a ſingle ſtyle of the ſame length; the petals are green on the outſide, whitiſh within, and have a grateful odour. After the flower is paſt, the germen ſwells to a large fruit the ſize of an Orange, having a hard ſhell, which incloſes a fleſhy viſcous pulp, of a yellowiſh colour, having many oblong plain ſeeds ſituated within it; the pulp of this fruit hath an agreeable flavour when ripe, ſo is frequently eaten in India, where they ſerve up the fruit, mixed with Sugar and Orange, in their deſerts, and is eſteemed a great delicacy.

This ſort is propagated by ſeeds, which muſt be procured from the places where it grows naturally; theſe muſt be ſown upon a good hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each tranſplanted into a ſmall pot filled with light kitchen-garden earth, and plunged into a hot-bed of tanners bark, ſhading them every day from the ſun, until they have taken freſh root, after which they may be treated in the ſame manner as the Annona;

but ſhould be ſparingly watered in the winter ſeaſon.

CREPIS. Lin. Gen. Plant. 819. Hieraicioides. Vaill. Act. R. Sc. 1721. Hieraicium. Tourn. Baſtard Hawkweed.

The CHARACTERS are,

It hath a flower compoſed of many hermaphrodite florets, which are included in a double empalement; the outer is ſhort, ſpreading, and falls off; the inner one is permanent, oval, and furrowed, having many narrow ſcales, which are contracted together at the top. The hermaphrodite florets are of one leaf; they are uniform, tongue-ſhaped, and are indented at the top in five parts; theſe ſpread over each other like the ſcales of fiſh; they have each five ſhort hairy ſtamina, terminated by cylindrical ſummits. The germen is ſituated in the center of the florets, ſupporting a ſlender ſtyle, crowned by two reflexed ſtigmas. The germen afterward becomes an oblong ſeed, crowned with a long feathery down, which ſits upon little foot-ſtalks.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia Æqualis. The flowers of this ſection are compoſed of hermaphrodite florets, which are fruitful.

The SPECIES are,

1. CREPIS (*Rubra*) foliis amplexicaulibus, lyrato-runcinatis. Vir. Cliff. 79. *Crepis with lyre-ſhaped leaves embracing the ſtalks.* Hieracium dentis leonis folio, flore ſuave rubente. C. B. P. 127. *Hawkweed with a Dandelion leaf.*
2. CREPIS (*Barbata*) foliis pinnatis angulatis, petiolatis, dentatis. Prod. Leyd. 126. *Crepis with angular, indented, winged leaves, having foot-ſtalks.* Hieracium foliis Cichorei ſylveſtris villoſis, odore Caſtorei. Bot. Monſp.
3. CREPIS (*Bœtica*) involucris calyce longioribus incurvatis, foliis lanceolatis dentatis. *Crepis with an incurved volucrum longer than the empalement, and ſpear-ſhaped indented leaves.* Hieracium medio-nigrum, Bœticum majus. Par. Bat. 185. *Greater Spaniſh Hawkweed with flowers black in the middle.*
4. CREPIS (*Alpina*) foliis amplexicaulibus, oblongis, acuminatis inferioribus, superné, ſummis inferné, denticulatis. Hort. Upſal. 238. *Crepis with oblong pointed leaves embracing the ſtalk, the lower being indented upward; and the upper downward.* Hieracium Alpinum Scorzoneræ folio. Tourn. Inſt. 472.

There are ſeveral other ſpecies of this genus, ſome of which grow naturally in England, and others are weeds in divers parts of Europe, ſo are rarely admitted into gardens, therefore I ſhall not enumerate them here.

The firſt ſort grows naturally in Apulia, but is now commonly cultivated in Engliſh gardens for ornament; it is an annual plant, which periſhes after it hath ripened ſeeds. This hath many ſpear-ſhaped leaves which ſpread on the ground, deeply jagged on their ſides; between them ariſe the branching ſtalks, which grow a foot and a half high, dividing into many ſlender branches, garniſhed with oblong leaves deeply indented on their edges, embracing the ſtalks with their baſe; the ſtalks are each terminated by one large radiated flower, of a ſoft red colour, compoſed of many half florets, which are ſucceeded by oblong ſeeds crowned with a feathery down. It flowers in June and July, and the ſeeds ripen in autumn. This plant, when bruiſed, emits an odour like bitter Almonds.

The ſeeds of this plant ſhould be ſown in the ſpring, on the borders of the flower-garden where they are deſigned to remain, ſo that if ſix or eight ſeeds are ſown in each patch, when the plants come up, they may be reduced to three or four; and if theſe are kept clean from weeds, they will require no other culture, excepting the putting ſmall ſticks down, to faſten the ſtalks, to prevent their being broken by winds or rain. If the ſeeds are ſown in autumn, or permitted to ſcatter, the plants will come up and live through the winter without ſhelter, and theſe will flower early in the ſpring.

The ſecond ſort grows naturally in the ſouth of France, and in Italy. This is a biennial plant, and ſometimes, when it is in poor ground, it will continue longer; it hath a thick tap-root, which ſtrikes deep into the ground, ſending out many ſmall fibres; the lower leaves are from four to five inches long, and about a quarter of an inch broad, having ſeveral deep jags on their edges, the ſegments ending in acute points; from the ſame root ariſes four or five ſtalks, which grow about nine or ten inches high, the lower part of theſe are garniſhed with leaves of the ſame form with thoſe near the root, but are ſmaller, and more jagged; the upper part of the ſtalks are naked, and branch out into two, and ſometimes three branches, each being terminated by one flower of a gold colour, inclining to copper, compoſed of many florets which are included in a ſingle empalement; the flowers are ſucceeded by oblong narrow ſeeds, crowned with a feathery down: the whole plant, when bruiſed, emits a ſtrong odour of Caſtor. It flowers in June, and the ſeeds ripen in autumn. This is frequently preſerved in gardens for the ſake of variety.

It is propagated by ſeeds in the ſame manner as the firſt ſort, but as this continues longer, the ſeeds need not be annually ſown. The plants will require no other culture but to keep them clean from weeds, and if the ſeeds are permitted to ſcatter, the plants will come up without any trouble, ſo need only be thinned where they are too cloſe.

The third ſort is an annual plant, which grows naturally in Spain, but is now frequently propagated in the flower-gardens for ornament. This puts out leaves near the root, which are nine inches long, and almoſt two broad in the middle, of a light green colour, and a little jagged on their edges; the ſtalks riſe a foot and a half high, dividing into many branches, garniſhed with leaves of the ſame form as thoſe at bottom, but ſmaller, and ſit cloſe to the branches; the flowers are produced at the end of the branches; theſe have a double empalement, compoſed of many long very narrow leaves; the outer ſeries are reflected downward, and turn upward again, and are inflexed at their extremities. The flowers are compoſed of many florets, which are ſtretched out on one ſide at the top like a tongue, theſe are cut at their extremities into four or five parts; they ſpread regularly in form of rays, and are ſituated over each other like ſcales of fiſh; there are two varieties of this, one with a deep yellow, and the other of a ſulphur colour inclining to white; but both have a dark black bottom or middle, ſo make a pretty appearance in a garden. It flowers in June and July, and the ſeeds ripen in autumn. This plant requires the ſame culture as the firſt, and is equally hardy, ſo that where the ſeeds are permitted to ſcatter, the plants will come up without care.

The fourth ſort grows naturally on the Alps; this is alſo an annual plant, which ſends out many oblong pointed leaves near the root; they are five inches long, and almoſt two broad at their baſe, leſſening gradually to a point; the upper part of theſe are ſlightly indented, but their lower parts are entire; the ſtalks are ſtrong and upright, riſing two feet high, dividing into three or four branches, which grow erect, and are terminated by pale white flowers, incloſed in a ſtrong hairy empalement, which contracts cloſe toward the top; the ſtalks are garniſhed with leaves of the ſame form as the lower, which embrace them with their baſe, where they are ſlightly indented, but their upper parts are entire; theſe leaves are hairy and rough. It flowers in June, and the ſeeds ripen in autumn. This requires the ſame culture as the firſt, and the ſeeds will ſcatter about the garden, ſo that if the plants are not deſtroyed, they will maintain themſelves without any care.

CRESCENTIA. Lin. Gen. Plant. 680. Cujete. Plum. Nov. Gen. 23. tab. 16. Calabaſh-tree.

The CHARACTERS are,

The flower hath one petal, which is irregular, having a *curved gibbous tube, whoſe brim is cut into five unequal ſegments, which are reflexed; this hath an empalement, which is ſhort, of one leaf, cut into two obtuſe ſegments, which are concave. It hath four ſtamina, two of which are of the length of the petal; the other are ſhorter, terminated by twin ſummits which are proſtrate. It hath an oval germen ſitting on a foot-ſtalk, ſupporting a long ſlender ſtyle, crowned by a roundiſh ſtigma. The germen afterward becomes an oval or bottle-ſhaped fruit, with a hard ſhell, incloſing many flat heart-ſhaped ſeeds.*

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia. The flower having two long and two ſhort ſtamina, and the ſeeds being included in a capſule.

The Species are,

1. Crescentia (*Cujete*) foliis lanceolatis, utrinque attenuatis. Hort. Cliff. 327. *Creſcentia with ſpear-ſhaped leaves, narrowed at both ends.* Cujete foliis oblongis anguſtis magno fructu ovato. Plum. Nov. Gen. 23. *Calabaſh-tree with oblong narrow leaves, and a large oval fruit.*
2. Crescentia (*Latifolia*) foliis oblongo-ovatis, fructu rotundo, cortice fragili. *Creſcentia with oblong oval leaves, and round fruit with a tender ſhell.* Cujete latifolia, fructu putamine fragili. Plum. Nov. Gen. 23. *Broad-leaved Calabaſh-tree whoſe fruit hath a tender ſhell.*

There are ſome varieties of theſe trees, which only differ in the ſize and ſhape of their fruit; but thoſe are variations which ariſe from ſeeds of the ſame tree, ſo are not to be enumerated as diſtinct ſpecies; but the two here mentioned are undoubtedly different ſpecies, for I have frequently raiſed them from ſeeds, and have never found either of them vary.

The firſt ſort grows naturally in Jamaica, and in all the Leeward Iſlands. This hath a thick trunk, covered with a whitiſh bark, which riſes from twenty to thiry feet high, having ſeveral knots all the length, and at the top divides into many branches, which ſpread every way, and form a large regular head, garniſhed with leaves which come out irregularly; ſometimes ſingle, at others many ariſe from the ſame knot; they are near ſix inches long, and one and a half broad in the middle, diminiſhing gradually to both ends; they are of a lucid green, and have very ſhort foot-ſtalks, with one midrib, and ſeveral tranſverſe veins running from that to the ſides. The flowers are produced from the ſide of the large branches, and ſometimes from the trunk, ſtanding upon long foot-ſtalks; their empalement is deeply divided into two obtuſe ſegments. The flower hath but one petal, which is irregular, having an incurved tube, which is divided at the brim into two irregular ſegments, which turn backward; theſe are of a greeniſh yellow colour, ſtriped and ſpotted with brown; the flowers are an inch and a half long, from the bottom of the tube to the extent of the upper ſegment. They have four ſlender ſtamina, of the ſame colour with the petal, which are of unequal lengths, two being full as long as the petal, and the other are much ſhorter, terminated by oblong ſummits, divided in the middle, which lie proſtrate on the ſtamina. From the lower part of the tube ariſes a long ſlender foot-ſtalk, ſupporting the oval germen, which hath a headed ſtigma ſitting cloſe on the top; the germen afterward turns to a large fruit, of different forms and ſize; they are often ſpherical, ſometimes they are oval, and at other times they have a contracted neck like a bottle; and are ſo large, as when the pulp and ſeeds are cleaned out, the ſhells will contain three pints or two quarts of liquid. Theſe fruit or ſhells, are covered with a thin ſkin of a greeniſh yellow when ripe, which is peeled off; and under this is a hard ligneous ſhell, incloſing a pale, yellowiſh, ſoft pulp, of a tart unſavory flavour, ſurrounding a great number of flat heart-ſhaped ſeeds.

The ſhells of this fruit are cleaned of their pulp, and the outer ſkin taken off, by the inhabitants of the iſlands, and dried; then they uſe them for drinking-cups, ſome of which are tipped with ſilver, and to the necks they faſten handles, and ſome of the long ſmall fruit are formed into the ſhape of ſpoons or ladles, and are uſed as ſuch; the round ones are cut through the middle, and are uſed as cups for Chocolate. The Indians put a number of ſmall ſtones into theſe ſhells, when cleared of the pulp, to make a ſort of rattle: in ſhort, they convert theſe ſhells into many ſorts of furniture, which is the principal uſe made of the fruit; for the pulp is ſeldom eaten, except by the cattle in the time of great droughts. The leaves and branches of this tree are alſo eaten by the cattle in times of ſcarcity. The wood of this tree is hard and ſmooth, ſo is frequently uſed for making ſaddles, ſtools, and other furniture.

The ſecond ſort ſeldom riſes more than fifteen or twenty feet high; this hath an upright trunk, covered with a white ſmooth bark, ſending out many lateral branches at the top, garniſhed with leaves three inches in length, and one and a quarter broad; theſe are ranged alternately on the branches, ſitting upon ſhort foot-ſtalks; they are of a deeper green than thoſe of the firſt ſort, and their edges are entire. The flowers come out from the ſide of the large branches and the trunk; theſe are ſmaller, and of a deeper yellow colour than thoſe of the firſt; the fruit of this is ſometimes round, at others oval, ſome being much larger than the other; the ſhells of this fruit are thin and very brittle, ſo are unfit for any purpoſes to which thoſe of the former are employed; the ſeeds are alſo much thinner, and the pulp is of a deeper yellow. The wood of this tree is hard, and very white, ſo might be uſeful, were it not for the plenty of other ſorts, which abound in many of the iſlands. This was found growing naturally in plenty at Campeachy by the late Dr. Houſtoun, who ſent the fruit to England.

Theſe trees are too tender to live abroad in England, ſo require a warm ſtove to be preſerved here. They are eaſily propagated by ſeeds, which muſt be procured from the countries where they grow naturally; the way is to have the entire fruit ſent over when fully ripe; for when the ſeeds are taken out of the pulp abroad, and ſent over hither, if they are long in their paſſage they will loſe their growing quality before they arrive, as I have often experienced. Theſe muſt be ſown on a good hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each planted into a ſmall halfpenny pot filled with light ſandy earth, and plunged into a hot-bed of tanners bark, obſerving to ſhade them from the ſun till they have taken freſh root; when they muſt be treated in the ſame manner as other tender plants, which are natives of the ſame countries. In winter they muſt be placed in the tan-bed of the bark-ſtove, and during that ſeaſon ſhould have but little water; in ſummer they will require to be gently watered two or three times a week, according to the warmth of the ſeaſon; and in hot weather they ſhould have a large ſhare of air admitted to them. With this management the plants will make great progreſs, and their leaves being of a fine green, they make a pretty variety in the ſtove, but have not as yet flowered in England.

CRESS the Winter. }

CRINUM. Lin. Gen. Plant. 366. Lilio-Aſphodelus. Com. Rar. 14. Dillen. Hort. Elth. 194. Aſphodel Lily.

The Characters are,

The involucrum is compoſed of two oblong leaves, in form of a ſheath or cover, which dries and is reflexed. The flower hath one petal, which is funnel-ſhaped, having a long tube, deeply cut at the top into ſix ſegments which are reflexed. It hath ſix long ſtamina, which are inſerted in the tube of the petal, and are ſtretched out beyond the flower, ſpreading open; theſe are terminated by oblong proſtrate ſummits, riſing at one end; the germen is ſituated *in the bottom of the flower, ſupporting a long ſlender ſtyle, crowned by a ſmall trifid ſtigma. The germen afterward becomes an oval capſule with three cells, each containing one or two oval ſeeds.*

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, the flower having ſix ſtamina and one ſtyle.

The Species are,

1. Crinum (*Africanum*) foliis ſublanceolatis planis, corollis obtuſis. Lin. Sp. Plant. 292. *Crinum with plain ſpear-ſhaped leaves, and obtuſe petals.* Hyacinthus Africanus tuberoſus, flore cæruleo umbellato. Hort. Amſt. 1. p. 133. *African tuberous Hyacinth, with a blue umbellated flower.*

The firſt ſort grows naturally at the Cape of Good Hope, from whence it was brought to the gardens in Holland, and hath ſince been ſpread into moſt of the curious gardens in Europe. The root of this plant is compoſed of many thick fleſhy fibres, diverging from the ſame head, which ſtrike deep into the ground, and put out many ſmaller fibres, which are white and fleſhy; from the ſame head ariſes a cluſter of leaves ſurrounding each other with their baſe, ſo as to form a kind of herbaceous ſtalk, about three inches high, from which the leaves ſpread only two ways, appearing flat the other two. The flower-ſtalk ariſes by the ſide of theſe leaves, which is round, hollow, and near three feet high, terminated by a large head of flowers, included in a kind of ſheath, which ſplits into two parts, and is reflexed. The flowers ſtand each upon a foot-ſtalk about one inch long; they are tubulous, have but one petal, which is cut almoſt to the bottom, into ſix oblong blunt ſegments, which are waved on their edges; in the center is ſituated an oval three-cornered germen, ſupporting a long ſtyle, which is attended by ſix ſtamina, two of the ſame length, two ſomewhat ſhorter, and the two which reſt upon the lower ſegments are the ſhorteſt. The flowers are of a bright blue colour, and grow in large umbels, ſo make a fine appearance. They begin to flower in September, and frequently continue in beauty till ſpring, which renders them more valuable.

This plant is propagated by offſets, which come out from the ſide of the old plants, and may be taken off the latter end of June, at which time theſe plants are in their greateſt ſtate of reſt; when the plants ſhould be turned out of the pots, and the earth carefully cleared away from the roots, that the fibres of the offſets may be better diſtinguiſhed, which ſhould be ſeparated from thoſe of the old roots, being careful not to break their heads. But where they adhere ſo cloſely to the old plant, as not to be ſo ſeparated, they muſt be cut off with a knife, taking great care not to wound or break the roots of either the offſets or the parent plant. When theſe are parted, they ſhould be planted each into a ſeparate pot, filled with light kitchen-garden earth, and placed in a ſhady ſituation, where they may enjoy the morning ſun, giving them a little water twice a week, if the weather proves dry; but they muſt not have too much wet, eſpecially at this ſeaſon, when they are almoſt inactive; for as the roots are fleſhy and ſucculent, they are apt to rot with great moiſture. In about five weeks time the offſets will have put out new roots, when the pots may be removed to a more ſunny ſituation, and then they may have a little more water, which will ſtrengthen their flowering, but it muſt not be given them too liberally for the reaſons before given. In September they will put out their flower-ſtalks, and toward the end of that month the flowers will begin to open; when, if the weather ſhould not be good, they ſhould be removed under ſhelter, to prevent the flowers from being injured by froſt or too much wet; but they ſhould have as much free air as poſſible, otherwiſe the flowers will be pale-coloured and weak. Toward the end of October they ſhould be removed into the green-houſe, and placed where they may enjoy as much free air as poſſible, and not be over-hung by other plants; and during the winter, they may have a little water once a week or oftener in mild weather, but in froſt they ſhould be kept dry. This plant only requires protection from froſt and moiſture, ſo ſhould not have any artificial warmth in winter, and muſt be placed in the open air in ſummer.

The ſecond ſort hath large bulbous roots, which ſend out many large fleſhy fibres, having bulbs formed at their ends; the leaves are near three feet long, hollow on their upper ſide, and cloſely fold over each other at their baſe, ſpreading out on every ſide; the outer leaves generally turn downward at the top; they are of a deep green, obtuſe at their points, with a ridge on their under ſide. The flower-ſtalk ariſes on one ſide the leaves, which is thick, ſucculent, hollow in the middle, and a little compreſſed on two ſides; this grows two feet high or more, and is of the ſame colour with the leaves, and are terminated by large umbels of flowers, with a ſheath or cover, which ſplits lengthways, and reflexed back to the ſtalk, where it dries and remains; the tubes of the flowers are narrow, near four inches long, and the upper part is deeply cut into ſix long ſegments, which are reflexed back almoſt to the tube; in the center ariſes the ſtyle, attended by ſix long ſtamina, which ſtand out beyond the petal, and is terminated by oblong proſtrate ſummits of a yellow colour. After the flowers are paſt, the germen, which is ſituated at the bottom of the tube, becomes a large, roundiſh, three-cornered capſule, having three cells, two of which are generally abortive, and the third hath one or two irregular bulbs, which if planted produce young plants.

The third ſort hath broader leaves than the ſecond, which are plain, and not hollowed on their upper ſide, but they are ſhorter and of a lighter green; theſe embrace each other at their baſe; by the ſide of theſe ariſe the flower-ſtalk, which is compreſſed and hollow, riſing about two feet high, and terminated by large umbels of white flowers, like thoſe of the former ſort, but the ſegments of the petal are broader and not ſo much reflexed.

The fourth ſort hath roots like thoſe of the ſecond ſort; the leaves of this are narrower at their baſe, and are ſtained with purple on their under ſide; the flower-ſtalks are purple, and grow to the ſame height as thoſe of the ſecond; the flowers are in ſhape like them, but the tube is purple, and the ſegments have a purple ſtripe running through them; the ſtamina alſo are purple, which renders this more beautiful than either of the other ſorts; and theſe differences are conſtant in all the plants which riſe from ſeeds, ſo there can be no doubt of its being a diſtinct ſort.

Theſe three ſorts grow naturally in both Indies, ſo are very tender, therefore muſt be kept in a warm ſtove, otherwiſe they will not thrive in England; they are eaſily propagated by offſets, which the roots put out in plenty; or by the bulbs which ſucceed the flowers, and ripen perfectly here. Theſe muſt be planted in pots filled with rich earth, and if plunged into the tan-bed in the ſtove, the plants will make greater progreſs and flower oftener, than when they are placed on ſhelves; though in the latter way they will ſucceed very well, provided they are kept in a good temperature of heat. The roots ſhould be tranſplanted in the ſpring, and all the offſets taken off, otherwiſe they will fill the pots and ſtarve the old plants: they muſt be frequently refreſhed with water, but it muſt not be given them too plentifully, eſpecially in winter. Theſe ſorts flower at every ſeaſon of the year, which renders them more valuable; for where there are many plants, there will be almoſt a perpetual ſucceſſion of flowers, which emit a very agreeable odour.

CRITHMUM. Lin. Gen. Plant. 303. Tourn. Inſt. R. H. 317. tab. 169. Samphire.

The Characters are,

It is a plant with an umbelliferous flower; the great umbel is hemiſpherical, and compoſed of many ſmaller of the ſame figure; the involucrum of the general umbel is compoſed of ſeveral ſpear-ſhaped leaves; thoſe of the particular umbels have very narrow leaves the length of the umbel; the general umbel is uniform; the flowers have five oval inflexed petals, which are almoſt equal; they have five ſtamina the length of the petals, which are terminated by roundiſh ſummits. The germen is ſituated under the flower, ſupporting two reflexed ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes an oval compreſſed fruit, dividing into two parts, each having one compreſſed, elliptical, furrowed ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, the flowers having five ſtamina and two ſtyles.

The Species are,

1. Crithmum (*Maritimum*) foliolis lanceolatis carnoſis. Hort. Cliff. 98. *Samphire with ſpear-ſhaped fleſhy leaves.* Crithmum ſive Fœniculum maritimum minus. C. B. P. 288. *Samphire.*
2. Crithmum (*Pyrenaicum*) foliolis lateralibus bis trifidis. Hort. Cliff. 98. *Samphire whoſe ſmaller leaves on their ſides are doubly trifid.* Apium Pyrenaicum thapſicæ facie. Tourn. Inſt. 305.

The firſt ſort grows upon the rocks by the ſea-ſide, in many parts of England. This hath a root compoſed of many ſtrong fibres, which penetrate deep into the crevices of the rocks, ſending up ſeveral fleſhy ſucculent ſtalks, which riſe about two feet high, garniſhed with winged leaves, which are compoſed of three or five diviſions, each of which hath three or five ſmall, thick, ſucculent leaves near half an inch long; the foot-ſtalks of the leaves embrace the ſtalks at their baſe. The flowers are produced in circular umbels at the top of the ſtalks; theſe are of a yellow colour, compoſed of five petals, which are near equal in ſize, and are afterward ſucceeded by ſeeds ſomewhat like thoſe of Fennel, but are larger. This herb is pickled, and eſteemed very comfortable to the ſtomach, and is very agreeable to the palate; it provokes urine gently, removes the obſtructions of the viſcera, and creates an appetite; it is commonly uſed for ſauce; it is gathered on the rocks where it grows naturally, but the people who ſupply the markets with it, ſeldom bring the right herb, but inſtead of it they bring a ſpecies of Aſter, which is called golden Samphire, but hath a very different flavour from the true, nor has it any of its virtues. This grows in greater plenty, and upon the plain ground which is overflowed by the ſalt water; whereas, the true Samphire grows only out of the crevices of perpendicular rocks, where it is very difficult to come at. It flowers in July, and the ſeeds ripen in autumn.

This plant is with difficulty propagated in gardens, nor will it grow ſo vigorous with any culture, as it does upon rocks; but if the plants are planted on a moiſt gravelly ſoil, they will thrive tolerably well, and may be preſerved ſome years. It may be propagated either by ſeeds or parting the roots.

The ſecond ſort is by Tournefort ranged in his genus of Apium. This grows naturally on the Pyrenean mountains. It is a biennial plant, which doth not flower till the ſecond year, and periſhes ſoon after the ſeeds are ripe. There are two or three ſorts of this plant, which differ in their outer appearance, but I am not certain of their being diſtinct ſpecies. One of theſe is titled by Mr. Ray, Apium montanum ſive petræum album. This is of humbler growth than the other; the ſmall leaves are broader, and not ſo much cut on their edges, and are of a paler green: theſe plants are preſerved in a few gardens for the ſake of variety; they are propagated by ſeeds, which ſhould be ſown in the autumn where they are deſigned to remain, and will require no other culture but to keep them clean from weeds, and thin them where they are too cloſe.

CRISTA GALLI. See **Pedicularis.**

CRISTA PAVONIS. See **Poinciana.**

CROCUS. Lin. Gen. Plant. 53. Tourn. Inſt. R. H. 350. tab. 183, 184. [is ſo called of the youth Crocus, who (as the poets feign) loved Smilax with ſo violent a paſſion, that, by reaſon of impatience, he was turned into a flower of his name.] Saffron.

The Characters are,

It hath a ſpatha or ſheath of one leaf. The flower hath one petal, which is deeply cut into ſix oblong ſegments, which are equal. It hath three ſtamina which are ſhorter than the petal, terminated by arrow-pointed ſummits. The roundiſh germen is ſituated at the bottom of the tube, ſupporting a ſlender ſtyle, crowned by three twiſted ſtigmas, which are ſawed. The germen afterward becomes a roundiſh fruit, with three cells, filled with roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, the flower having three ſtamina and one ſtyle.

The Species are,

1. Crocus (*Sativus*) ſpathâ univalvi radicali, corollæ tubo longiſſimo. Lin. Sp. Plant. 36. *Saffron with a ſpatha near the root, having one valve, and a long tube to the flower.* Crocus ſativus. C. B. P. 65. *Cultivated Saffron.*
2. Crocus (*Autumnalis*) ſpathâ univalvi pedunculato, corollæ tubo breviſſimo. *Saffron with a ſpatha on the foot-ſtalk, having one valve, and a very ſhort tube to the flower.* Crocus juncifolius autumnalis, flore magno purpuraſcente. Boerh. Ind. alt. 2. 120.
3. Crocus (*Vernus*) ſpathâ bivalvi radicali, floribus ſeſſilibus. *Crocus with a bivalve ſpatha near the root, and flowers ſitting cloſe to the ground.* Crocus vernus latifolius, flavo flore varius. C. B. P. 66. *Commonly called Biſhop's Crocus.*
4. Crocus (*Biflora*) ſpathâ biflorâ corollæ tubo tenuiſſimo. *Crocus with two flowers in each ſpatha, having very narrow tubes.* Crocus vernus, ſtriatus, vulgaris. Par. Bat. *Ordinary, ſpring, ſtriped Crocus.*

There are a much greater variety of theſe flowers than are here enumerated; but as moſt, if not all of them are only ſeminal variations, I thought it would be needleſs to particularize them here, eſpecially as there are frequently new varieties obtained from ſeeds. Thoſe which are here enumerated, I think muſt be allowed to be ſpecifically different, ſince they have many diſtinguiſhing characters, which are ſufficient to determine the ſpecific difference in plants.

The firſt ſort is the plant which produces the Saffron, which is a well known drug: this hath a roundiſh bulbous root as large as a ſmall Nutmeg, which is a little compreſſed at the bottom, and is covered with a coarſe, brown, netted ſkin; from the bottom of this bulb is ſent out many long fibres, which ſtrike pretty deep into the ground; from the upper part of the root come out the flowers, which, together with the young leaves, whoſe tops juſt appear, are cloſely wrapped about by a thin ſpatha or ſheath, which parts within the ground, and opens on one ſide. The tube of the flower is very long, ariſing immediately from the bulb, without any foot-ſtalk, and at the top is divided into ſix oval obtuſe ſegments, which are equal, of a purple blue colour. In the bottom of the tube is ſituated a roundiſh germen, ſupporting a ſlender ſtyle, which is not more than half the length of the petal, crowned with three oblong golden ſtigmas (which is the Saffron;) theſe ſpread aſunder each way. The ſtyle is attended by three ſtamina, whoſe baſes are inſerted in the tube of the petal, and riſe to the height of the ſtyle, where they are terminated by arrow-pointed ſummits. This plant flowers in October, and the leaves keep growing all the winter, but it never produces any ſeeds here.

The ſecond ſort grows naturally on the Alps and Helvetian mountains: this hath a ſmaller bulbous root than the firſt, which is more compreſſed; the flowers appear about the ſame ſeaſon with the former, but they riſe with a ſhort foot-ſtalk, having a ſhort ſpatha or ſheath juſt below the flower, which covers it before it expands. The tube of the flower is very ſhort, the petal being divided almoſt to the bottom, and the ſegments terminate in acute points; the ſtamina and ſtyle are ſhort, and the leaves of the plant are very narrow. The flower is of a deep blue; but there is a variety of this with a ſky blue flower, which is ſuppoſed to have been produced by ſeeds. Dr. Linnæus has ſuppoſed theſe, and alſo all the varieties of the Spring Crocus, to be but one ſpecies, but there can be no doubt of theſe being diſtinct from thoſe of the Spring.

The third ſort hath a pretty large, compreſſed, bulbous root, covered with a light, brown, netted ſkin, from which ariſe four or five leaves, like thoſe of the the other Vernal Crocuſes, of a purpliſh colour on their lower parts; from between theſe come out one or two flowers of a deep yellow colour, ſitting cloſe between the young leaves, never riſing above two inches high; theſe have an agreeable odour; the outer ſegments of the petal are marked with three black ſtreaks or ſtripes running lengthways from the bottom to the top of the ſegment; theſe are narrower than the inner ſegments. From the double arrangement of theſe ſegments ſome have called it a double flower. Theſe ſegments have dark purple bottoms, and the tube of the flower hath as many purple ſtripes as there are ſegments in the petal. Out of the center of the tube ariſes a ſlender ſtyle, crowned by a golden ſtigma, which is broad and flat, and is attended by three ſlender ſtamina of the ſame length, terminated by yellow ſummits. After the flower is paſt, the germen puſhes out of the ground, and ſwells to a roundiſh three-cornered ſeed-veſſel, which opens in three parts, and is filled with roundiſh brown ſeeds. This is one of the earlieſt Crocuſes in the ſpring.

The fourth ſort riſes with a few very narrow leaves, which are, together with the flower-buds, cloſely wrapped round by a ſpatha or ſheath, out of which ariſe two flowers, one of which hath a longer tube than the other, but theſe are very ſlender, and do not riſe much above the ſpatha; there the petal enlarges, and is divided into ſix obtuſe ſegments, which are of equal ſize; they are of a dirty white on their outſide, with three or four purple ſtripes in each; the inſide of the petal is of a purer white; the ſtamina and ſtyle are nearly the ſame as thoſe of the former ſort. This is one of the earlieſt ſorts which flowers in the ſpring.

The VARIETIES of the autumnal Crocus are,

1. The ſweet-ſmelling autumnal Crocus, whoſe flowers come before the leaves. C. B. This is our ſecond ſort.
2. The autumnal mountain Crocus. C. B. This hath a paler blue flower.
3. The many flowering bluiſh autumnal Crocus. C. B. This hath many ſky blue flowers.
4. The ſmall flowering autumnal Crocus. C. B. This hath a ſmall deep blue flower.

The VARIETIES of the Spring Crocus are,

1. Broad-leaved, purple, variegated, Spring Crocus. C. B. This hath broad leaves and a deep blue flower ſtriped.
2. Broad-leaved Crocus of the ſpring with a purple flower. C. B. This hath a plain purple flower.
3. Broad-leaved Spring Crocus with a Violet-coloured flower. C. B. This hath a large deep blue flower.
4. Spring Crocus, with a white flower and a purple bottom. C. B.
5. Broad-leaved, white, variegated, Spring Crocus. C. B.
6. Broad-leaved Spring Crocus, with many purple Violet flowers ſtriped with white. C. B.
7. Broad-leaved Spring Crocus with an Aſh-coloured flower.
8. Broad-leaved Spring Crocus with a large yellow flower. C. B.
9. Broad-leaved Spring Crocus with a ſmaller and paler yellow flower. C. B.
10. Broad-leaved Spring Crocus, with ſmaller yellow flowers ſtriped with black.
11. Narrow-leaved Spring Crocus with a ſmaller brimſtone-coloured flower.
12. Narrow-leaved Spring Crocus with a ſmall white flower.

Theſe are the principal varieties which I have obſerved in the Engliſh gardens, but there are many more mentioned in the foreign catalogues of flowers, many of which are ſo nearly alike, as ſcarce to be diſtinguiſhed; and if the ſeeds of theſe flowers were ſown, there might be a greater variety of them obtained than is at preſent; but as they propagate very faſt by offsets, the ſeeds are very rarely regarded.

All theſe ſeveral varieties of Crocuſes are very hardy, and will increaſe exceedingly by their roots, eſpecially if they are ſuffered to remain two or three years unremoved; they will grow in almoſt any ſoil or ſituation, and are very great ornaments to a garden early in the ſpring of the year, before many other flowers appear. They are commonly planted near the edges of borders on the ſides of walks; in doing of which, you ſhould be careful to plant ſuch ſorts in the ſame line as flower at the ſame time, and are of an equal growth, otherwiſe the lines will ſeem imperfect. Theſe roots, loſeing their fibres with their leaves, may then be taken up, and kept dry until the beginning of September, obſerving to keep them from vermin, for the mice are very fond of them. When you plant theſe roots (after having drawn a line upon the border,) make holes with a dibble about two inches deep or more, according to the lightneſs of the ſoil, and two inches diſtance from each other, in which you muſt place the roots with the bud uppermoſt; then with a rake fill up the holes in ſuch a manner as that the upper part of the root may be covered an inch or more, being careful not to leave any of the holes open; for this will entice the mice to them, which, when once they have found out, will deſtroy all your roots, if they are not prevented.

This is the way in which theſe flowers are commonly diſpoſed in gardens, but the better way is to plant them ſix or eight near each other in bunches between ſmall ſhrubs, or on the borders of the flower-garden; where, if the varieties of theſe flowers are planted in different patches, and properly intermixed, they will make a much better appearance than when they are diſpoſed in the old method of ſtrait edgings.

In January, if the weather is mild, the Crocus will often appear above ground; and in February their flowers will appear, before the green leaves are grown to any length, ſo that the flower ſeems at firſt to be naked; but ſoon after the flowers decay, the green leaves grow to be ſix or eight inches long, which ſhould not be cut off until they decay, notwithſtanding they appear a little unſightly; for by cutting off the leaves, the roots will be ſo weakened as not to arrive at half their uſual bigneſs, nor will their flowers the ſucceeding year be half ſo large. Their ſeeds are commonly ripe about the latter end of April, or the beginning of May, when the green leaves begin to decay.

The autumnal Crocuſes are not ſo great increaſers as are thoſe of the ſpring, nor do they produce ſeeds in our climate; ſo that they are leſs common in the gardens, except the true Saffron, which is propagated for uſe in great plenty in many parts of England; theſe muſt be taken up every third year, as was directed for the Spring Crocuſes, otherwiſe the roots will run long, and produce no flowers; but they ſhould not be kept out of the ground longer than the beginning of Auguſt, for they commonly produce their flowers the beginning of October; ſo that if they remain too long out of the ground, they will not produce their flowers ſo ſtrong, nor in ſuch plenty, as when they are planted early.

The method of cultivating Saffron being ſomewhat curious, I thought it not improper to inſert in this place an abſtract of it, as it was preſented to the Royal Society by Dr. James Douglaſs.

As Saffron grows at preſent moſt plentifully in Cambridgeſhire, and has grown formerly in ſeveral other counties of England, the method of culture does not, I believe, vary much in any of them, and therefore I judge it ſufficient to ſet down here the obſervations which I employed proper perſons, in different ſeaſons, to make, in the years 1723, 1724, 1725, and 1728, up and down all that large tract of ground that lies between Saffron-Walden and Cambridge, in a circle about ten miles diameter.

In that county Saffron has been cultivated, and therefore it may be reaſonably expected, that the inhabitants thereof are more thoroughly acquainted with it than they are any where elſe.

I ſhall begin with the choice and preparation of the ground. The greateſt part of the tract already mentioned is an open level country, with few incloſures; and the cuſtom there is, as in moſt other places, to crop two years, and let the land be fallow the third. Saffron is generally planted upon fallow ground, and, all other things being alike, they prefer that which has borne Barley the year before.

The Saffron grounds are ſeldom above three acres, or leſs than one; and in chooſing, the principal thing they have regard to is, that they be well expoſed, the ſoil not poor, nor a very ſtiff clay, but a temperate dry mould, ſuch as commonly lies upon chalk, and is of an Hazel colour; though if every thing elſe anſwers, the colour of the mould is pretty much neglected.

The ground being made choice of, about Lady-Day, or the beginning of April, it muſt be carefully ploughed, the furrows being drawn much cloſer together, and deeper, if the ſoil will allow it, than is done for any kind of corn; and accordingly, the charge is greater.

About five weeks after, during any time in the month of May, they lay between twenty and thirty loads of dung upon each acre, and having ſpread it with great care, they plough it in as before. The ſhorteſt rotten dung is the beſt; and the farmers, who have the conveniency of making it, ſpare no pains to make it good, being ſure of a proportionable price for it. About Midſummer they plough a third time, and between every ſixteen feet and an half, or pole in breadth, they leave a broad furrow or trench, which ſerves both as a boundary to the ſeveral parcels, when there are ſeveral proprietors to one incloſure, and to throw the weeds in at the proper ſeaſon.

To this head likewiſe belongs the fencing of the grounds, becauſe moſt commonly, though not always, that is done before they plant. The fences conſiſt of what they call dead hedges, or hurdles, to keep out not only cattle of all ſorts, but eſpecially hares, which would otherwiſe feed on the Saffron leaves during the winter.

About the weather we need not only obſerve, that the hotteſt ſummers are certainly the beſt, and therewith, if there be gentle ſhowers from time to time, they can hardly miſs of a plentiful crop, if the extreme cold, ſnow, or rain of the foregoing winter have not prejudiced the heads.

The next general part of the culture of Saffron is, planting, or ſetting the roots; the only inſtrument uſed for which is a narrow ſpade, commonly termed a ſpit ſhovel.

The time of planting is commonly in the month of July, a little ſooner or later, according as the weather anſwer. The method is this: one man with his ſpit ſhovel raiſes between three and four inches of earth, and throws it before him about ſix or more inches; two perſons, generally women, following with heads, place them in the fartheſt edge of the trench he makes, at three inches diſtance from each other, or thereabouts; as ſoon as the digger or ſpitter has gone once the breadth of the ridge, he begins again at the other ſide, and digging as before, covers the roots laſt ſet, and makes the ſame room for the ſetters to place a new row, at the ſame diſtance from the firſt, that they are from one another. Thus they go on, till a whole ridge, containing commonly one rod, is planted; and the only nicety in digging is, to leave ſome part of the firſt ſtratum of earth untouched, to lie under the roots, and, in ſetting, to place the roots directly upon their bottom.

What ſort of roots are to be preferred ſhall be ſhewn under the fourth head, but it muſt be obſerved in this place, that formerly, when roots were very dear, they did not plant them ſo thick as they do now; and that they have always ſome regard to the ſize of the roots, placing the largeſt at a greater diſtance than the ſmall ones.

The quantity of roots planted in an acre, is generally about 16 quarters, or 128 buſhels, which, according to the diſtances left between them, as before aſſigned, and ſuppoſing all to be an inch in diameter one with another, ought to amount to 392,040 in number.

From the time that the roots are planted, till about the beginning of September, or ſometimes later, there is no more labour about them; but as they then begin to ſpire, and are ready to ſhew themſelves above ground (which is known by digging a few out of the earth,) the ground muſt be carefully pared with a ſharp hoe, and the weeds, &c. raked into the furrows, otherwiſe they would hinder the growth of the plants.

In ſome time after appear the Saffron flowers, and this leads us to the third branch of our preſent method. The flowers are gathered as well before as after they are full blown, and the moſt proper time for this is early in the morning. The owners of the Saffron get together a ſufficient number of hands, who place themſelves in different parts of the field, who pull off the whole flowers, and throw them handful by handful into a baſket, and ſo continue till all the flowers are gathered, which happens commonly about ten or eleven o'clock.

Having then carried home all they have got, they immediately ſpread them upon a large table, and fall to picking out the filamenta ſtyli, or chives, and together with them a pretty long proportion of the ſtylus itſelf, or ſtring to which they are joined; the reſt of the flower they throw away as uſeleſs. The next morning they return into the field again, whether it be wet or dry weather, and ſo on daily, even on Sundays, till the whole crop be gathered.

The chives being all picked out of the flowers, the next labour about them is to dry them on the kiln. The kiln is built upon a thick plank (that it may be moved from place to place) ſupported by four ſhort legs; the outſide conſiſts of eight pieces of wood about three inches thick, in form of a quadrangular frame, about twelve inches ſquare at the bottom on the inſide, and twenty-two inches at top, which is likewiſe equal to the perpendicular height of it. On the foreſide is left a hole about eight inches ſquare, and four inches above the plank, through which the fire is put in; over all the reſt laths are laid pretty thick, cloſe to one another, and nailed to the frame already mentioned, and then are plaiſtered over on both ſides, as are alſo the planks at bottom very thick, to ſerve for a hearth. Over the mouth, or wideſt part, goes a hair cloth, fixed to the ſides of the kiln, and likewiſe to two rollers, or moveable pieces of wood, which are turned by wedges or ſcrews, in order to ſtretch the cloth. Inſtead of the hair cloth, many people now uſe a net-work, or iron wire, with which it is obſerved that the Saffron dries ſooner, and with leſs quantity of fuel; but the difficulty in preſerving the Saffron from burning, makes the hair cloth be preferred by the niceſt judges in drying.

The kiln is placed in a light part of the houſe, and they begin by laying five or ſix ſheets of white paper on the hair cloth, upon which they ſpread the wet Saffron between two and three inches thick; this they cover with other ſheets of paper, and over theſe lay a coarſe blanket five or ſix times doubled, or, inſtead thereof, a canvas pillow filled with ſtraw; and after the fire has been lighted for ſome time, the whole is covered with a board, having a large weight upon it.

At firſt they give it a pretty ſtrong heat, to make the chives ſweat (as their expreſſion is;) and in this, if they do not uſe a great deal of care, they are in danger of ſcorching, and ſo of ſpoiling all that is on the kiln.

When it has been thus dried about an hour, they take off the board, blanket, and upper papers, and take the Saffron off from that which lies next it, raiſing at the ſame time the edges of the cake with a knife; then laying on the paper again, they ſlide in another board between the hair cloth and upper papers, and turn both papers and Saffron upſide-down, afterwards covering them as above.

The ſame heat is continued for an hour longer; then they look on the cake again, free it from the papers, and turn it; then they cover it, and lay on the weight as before. If nothing happens amiſs during theſe firſt two hours, they reckon the danger to be over; for they have nothing more to do but to keep a gentle fire, and to turn their cakes every half hour till thoroughly dry, for the doing of which as it ought, there are required full twenty-four hours.

In drying the larger plump chives they uſe nothing more, but towards the latter end of the crop, when theſe come to be ſmaller, they ſprinkle the cake with a little ſmall beer, to make it ſweet as it ought; and they begin now to think, that uſing two linen cloths next the cake, inſtead of the two innermoſt papers, may be of ſome advantage in drying, but this practice is followed as yet but by few.

Their fire may be made of any kind of fuel, but that which ſmokes the leaſt is beſt, and charcoal, for that reaſon, is preferred to any other.

What quantity of Saffron a firſt crop will produce, is very uncertain; ſometimes five or ſix pounds of wet chives are got from one rood, ſometimes not above one or two, and ſometimes not enough to make it worth while to gather and dry it; but this is always to be obſerved, that about five pounds of wet Saffron go to make one pound of dry, for the firſt three weeks of the crop, and ſix pounds during the laſt week; and when the heads are planted very thick, two pounds of dried Saffron may, at a medium, be allowed to an acre for the firſt crop, and twenty-four pounds for the two remaining, the third being conſiderably larger than the ſecond.

In order to obtain theſe, there is only a repetition to be made every year of the labour of hoeing, gathering, picking, and drying, in the ſame manner as before ſet down, without the addition of any thing new, except that they let cattle into the fields, after the leaves are decayed, to feed upon the weeds, or, perhaps, mow them for the ſame uſe.

About the Midſummer after the third crop is gathered, the roots muſt be all taken up and tranſplanted; the management requiſite for which, is the fourth thing to be treated of. To take up the Saffron heads, or break up the ground (as the term is,) they ſometimes plough it, ſometimes uſe a forked kind of hoe, called a pattock, and then the ground is harrowed once or twice over; during all which time of ploughing, or digging, and harrowing, fifteen or more people will find work enough to follow and gather the heads as they are turned up.

They are next to be carried to the houſe in ſacks, and there cleaned and raſed; this labour conſiſts in cleaning the roots thoroughly from earth, and from the remains of old roots, old involucra, and excreſcences, and thus they become fit to be planted in new ground immediately, or to be kept for ſome time without danger of ſpoiling.

The quantity of roots taken up, in proportion to thoſe which were planted, is uncertain; but at a medium, it may be ſaid, that allowing for all the accidents which happened to them in the ground, and in breaking up from each acre, may be had twenty-four quarters of clean roots, all fit to be planted.

The owners are ſure to chooſe for their own uſe the largeſt, plumpeſt, and fatteſt roots, but do leaſt of all approve the longeſt pointed ones, which they call ſpickets, or ſpickards, for very ſmall, round, or flat roots, are ſometimes obſerved to flower well.

This is the whole culture of Saffron in the county above-mentioned, and we have only now to conſider the charges and profits which may be ſuppoſed, one year with another, to attend that branch of agriculture; and of theſe I have drawn up the following computation for one acre of ground, according to the price of labour in this country.

	l.	s.	d.
Rent for three years	3	0	0
Ploughing for three years	0	18	0
Dunging	3	12	0
Hedging	1	16	0
Spitting and ſetting the heads	1	12	0
Weeding or paring the ground	1	4	0
Gathering and picking the flowers	6	10	0
Drying the flowers	1	6	0
Inſtruments of labour for three years, with the kiln, about	0	10	0
Ploughing the ground once, and harrowing twice	0	12	0
Gathering the Saffron heads	1	0	0
Raiſing the heads	1	12	0
Total charge	23	12	0

This calculation is made upon ſuppoſition, that an acre of ground yields twenty-ſix pounds of nett Saffron in three years, which I ſtated only as a mean quantity between the greateſt and the leaſt, and therefore the price of Saffron muſt be judged accordingly, which I think cannot be done better than by fixing it at 30 ſhillings per pound; ſince in very plentiful years it is ſold at twenty, and is ſometimes worth between three and four pounds; at this rate, twenty-ſix pounds of Saffron are worth thirty-nine pounds, and the nett profits of an acre of ground producing Saffron, will, in three years, amount to fifteen pounds, thirteen ſhillings, or about five pounds four ſhillings yearly.

This, I ſay, may be reckoned the nett profit of an acre of Saffron, ſuppoſing that all the labour were to be hired for ready money; but as the planter and family do a conſiderable part of the work themſelves, ſome of this expence is ſaved; that is, by planting Saffron, he may not only reaſonably expect to clear about five pounds yearly per acre, but alſo to maintain himſelf and family for ſome part of each year; and it is upon this ſuppoſition only, that the reſult of other computations can be ſaid to have any tolerable degree of exactneſs, but the calculations themſelves are undoubtedly very inaccurate.

I have ſaid nothing here concerning the charge in buying, or profits in ſelling, the Saffron heads, becauſe, in many large tracts of ground, theſe muſt at length balance one another, while the quantity of ground planted yearly continues the ſame, which has been pretty much the caſe for ſeveral years paſt.

Dr. Patrick Blair, deſigning to treat concerning the Crocus, in his ſixth Decad of his Pharmaco-Botanologia, did, in the year 1725, ſend to me the following queries:

1. After what manner the ſpecies are propagated?
2. Whether the tap-root ſprings firſt, or the bulb?
3. At what ſeaſon the leaves ſpring forth?

To theſe queries I ſent him the following anſwer:

1. As to the propagation of the ſpecies.

This is only by the roots or offſets, which the old roots produce in great plenty, for I never ſaw any thing like a ſeed, or a ſeed-veſſel produced, though I have let ſtand great quantities of flowers purpoſely to try.

2. As to the query, Whether the tap-root ſprings firſt, and the bulb be afterwards formed?

As ſoon as the roots begin to ſhoot upwards, there are commonly two or three large tap-roots ſent forth from the ſide of the old root, which will run downright two inches and a half or more, into the ground; at the place where theſe bulbs firſt come out from the old one, will be formed a bulb ſometimes (though not always, as you will hear preſently;) and this tap-root decays. The bulb will increaſe in its bigneſs, till at laſt it quite falls off, and is then left entire, which commonly happens in April, when the green begins to decay; but many times theſe tap or carrotty roots never produce any bulbs, but always retain the ſame figure, and for ever after, I believe are barren; for I planted a parcel of theſe carrotty roots four years ago in a little bed, where they have ever ſince remained, but have not produced one ſingle flower, notwithſtanding they have produced a numerous offſpring of the ſame carrotty roots.

And the people about Saffron Walden are well appriſed of this barrenneſs, and therefore throw away all ſuch roots when they make a new plantation; but as this change of the root is not peculiar to the Saffron only, permit me to digreſs a little, to give you ſome account of this matter.

In the pariſh of Fulham, near London, the gardeners uſed to drive a great trade in the Jonquil, or Narciſſus juncifolius, flore multiplici, at which place the greateſt quantity of thoſe roots was raiſed for ſale, as perhaps was in any part of England, and turned to as great account for the maſter, as any crop they could employ their ground in, till of late years, that moſt of their roots have turned carrotty, and ſo proved barren, or have produced only ſingle flowers; ſo that the gardeners being hereby diſheartened, have thrown them out entirely, neglecting to cultivate them, ſatisfying themſelves with this reaſon, that their ground was tired with them.

But to return to the Crocus. Beſides thoſe roots already mentioned, there will be three or four ſmall bulbs formed upon the upper part of the root, and ſome underneath, which from the firſt appearance aſſume the round ſhape of its parent root, and have no tap-root belonging to them; thoſe on the upper part of the root rarely emit ſo much as a fibre, but receive their nouriſhment immediately from the old root; but thoſe on the under ſide ſend out many fibres all around, by which they draw their nouriſhment from the ground; theſe being parted from the old root much ſooner than the other, ſtand in need of fit organs for receiving their nouriſhment.

I have ſometimes taken up ſome, through the middle of which hath been a root of the Gramen caninum, or Couch Graſs, which ſome people have imagined had ſtrength enough to force its way through the Crocus root; but the truth is, the root of the Graſs cloſely adhering to the old root of the Crocus, juſt at the place where the young roots were emitted, theſe young roots being quick of growth, incloſed the root of the Graſs, and thus I have ſeen ſeveral roots run through each other in the ſame manner.

But beſides theſe offſets mentioned, directly upon the upper part of the root is one large root formed, of equal bigneſs with the old one, and this is the time that the root is Radix gemina, as Tournefort calls it; for they are not ſo at any other ſeaſon, and therefore I think it a very improper appellation; for when the new roots are perfectly formed, the old ones, with their coats, fall off and die, and leave the new roots all ſingle. This has occaſioned ſeveral people to doubt of what Tournefort had ſaid of the roots, till I took up ſome plants at that ſeaſon, and with them the two roots of equal bigneſs, i. e. the old at the bottom, and the new one at the top.

Dr. Blair alſo happening, in viewing a root, to be ſurpriſed with a different appearance from what he had ſeen before or heard of, ſent me another letter.

The manner of the root was thus; from the upper part of the bulb, where it ſends forth all the leaves within a common tunicle, at the exit there was an appendix about an inch and a half long, about the groſſneſs of a large turkey or gooſe-quill, cylindrical and blunt, without the leaſt radical fibre, by which it might receive the nouriſhment, ſmooth or poliſhed, and bluiſh in the ſurface, conſiſting of ſeveral circular lines, when cut tranſverſly; white, with a hard greeniſh center like a Carrot, when it hath puſhed forth the flowering-ſtem, not unlike the ſtolones of of ſome running root, ſuch as the Mints below ground, only the extremity deſcended obliquely, inſtead of aſcending, to ſend forth leaves to produce a new plant; and what is moſt remarkable, this did not happen to one or two plants, but to the whole bundle, which were above twenty diſtinct roots, differing in nothing but majus and minus; the bulb ſeemed at the ſame time to be pined and emaciated, though it emitted large radical fibres like thoſe of a Leak.

I having received this account from him by letter, ſent him the following anſwer:

I received yours in anſwer to my laſt, with the figure of the roots of ſome ſets of Crocus Autumnalis you have taken out of the ground; I have found a figure in Dodonæus which correſponds with it, and thoſe roots are no new thing with the Saffron gardeners, who always throw them away when they make freſh plantations.

Your figure does not agree with my tap-roots, as you will ſee by the figure taken as juſt from the life as I could. In mine you will find the bulb turned ſideways, which I ſtill find to be conſtant in all the roots I have examined, which have been a great many, and makes me ſuſpect theſe tap-roots are occaſioned by the accidental poſition of the roots in planting, which may retard the aſcending ſap, the flowering-ſtem being thereby turned into a crooked figure, and the tap-roots are full of longitudinal veſſels, of a conſiderable dimenſion; ſo that the greater attracting power of the ſap being hereby diverted downwards, the flower-ſtem may be quite deſtitute of proper nouriſhment.

The method you propoſe to remedy this inconveniency, will not do, for I have removed ſome of theſe roots at the ſeaſon when the tap-roots were forming, and this alone deſtroyed them all; ſo that I am perſuaded, the cutting them off entirely will kill them.

The method I uſed with the Jonquils was, to lay ſome tiles juſt under the roots, to prevent their running downwards, but this has not anſwered, nor do I think it poſſible wholly to recover them; for the alteration is not only in the root and flower, but alſo in the leaf and blade, which before was fiſtulous, but after this alteration in the root, becomes a plain ſulcated leaf, and if it ever bloſſoms after, the flowers are large and ſingle, which before were ſmall and double; but the Saffron, after the change of its roots, produces a ſmall narrow blade, ſeldom half the length of thoſe in a natural ſtate.

Upon this Dr. Blair formed this concluſion:

Theſe additional obſervations plainly ſhew, that neither the carrotty root, nor the blaſted tap-root, as I may call it, are merely accidental, or what may be called luſus naturæ, but certain diſeaſes incident to ſuch roots; for were they accidental, they would not have the ſame appearances to different perſons in different ſoils and climates, nor would ſo many taken up together have ſuch a reſemblance to each other, as I have twice obſerved.

CROTOLARIA. Lin. Gen. Plant. 771. Dill. Elth. 122. Tourn. Inſt. R. H. 644. [of Κρόταλον, *Gr.* rattle; becauſe its ſeeds in the pods, when ripe, make a rattling noiſe when ſhaken, or becauſe the infants of the Indians make uſe of the branches of this plant furniſhed with pods inſtead of rattles.]

The Characters are,

The empalement of the flower is divided into three large ſegments; the two upper reſting on the ſtandard, the lower is concave, trifid, and is ſituated below the keel. The flower is of the Butterfly kind; the ſtandard is large, heart-ſhaped and pointed; the wings are oval and half the length of the ſtandard; the keel is pointed and as long as the wings; it hath ten ſtamina which are united, ter-

minated by ſingle ſummits, and an oblong reflexed germen, ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a ſhort turgid pod with one cell, opening with two valves, and filled with kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria the flowers of this claſs and ſection having ten ſtamina joined in two bodies.

The Species are,

1. Crotolaria (*Verrucoſa*) foliis ſimplicibus ovatis, ſtipulis lunatis declinatis ramis tetragonis. Flor. Zeyl. 277. *Crotolaria with ſingle oval leaves, lunated declining ſtipulæ, and four-cornered branches.* Crotolaria Aſiatica folio ſingulari verrucoſo, floribus cæruleis. H. L. 199.
2. Crotolaria (*Piloſa*) foliis ſimplicibus lanceolatis piloſis, petiolis decurrentibus. *Crotolaria with ſingle, hairy, ſpear-ſhaped leaves, and running foot-ſtalks.* Crotolaria Americana, caule alato foliis piloſis, floribus in thyrſo luteis. Martyn. Cent. 43.
3. Crotolaria (*Sagittalis*) foliis ſimplicibus lanceolatis ſtipulis ſolitariis decurrentibus bidentatis. Hort. Cliff. 357. *Crotolaria with ſingle ſpear-ſhaped leaves, and ſingle ſtipulæ indented.* Crotolaria hirſuta minor Americana herbacea, caule ad ſummum ſagittato. H. L. 202.
4. Crotolaria (*Fruticoſa*) foliis ſimplicibus, lineari-lanceolatis hirſutis, petiolis decurrentibus, caule fruticoſo. *Crotolaria with ſingle, narrow, ſpear-ſhaped leaves, which are hairy, running foot-ſtalks, and a ſhrubby ſtalk.* Crotolaria frutеſcens hirſuta, flore luteo, ramulis alatis, foliis mucronatis. Houſt. MSS.
5. Crotolaria (*Juncea*) foliis ſimplicibus lanceolatis, petiolatis caule ſtriato. Hort. Cliff. 357. *Crotolaria with ſingle ſpear-ſhaped leaves having foot-ſtalks.* Crotolaria Benghalenſis foliis geniſtæ hirſutis. Pluk. Alm. 121.
6. Crotolaria (*Perfoliata*) foliis perfoliatis cordato-ovatis. Lin. Sp. Plant. 1005. *Crotolaria with oval heart-ſhaped leaves perforated by the ſtalks.* Crotolaria perfoliatæ folio. Hort. Elth. 122. tab. 102.
7. Crotolaria (*Retuſa*) foliis ſimplicibus, oblongis cuneiformibus retuſis. Flor. Zeyl. 276. *Crotolaria with ſingle, oblong, wedge-ſhaped leaves, reflexed at the top.* Crotolaria Aſiatica, floribus luteis, folio ſingularo cordiformi. H. L. 200.
8. Crotolaria (*Villoſa*) foliis ſimplicibus ovatis villoſis, petiolis ſimpliciſſimis, ramis teretibus. Hort. Cliff. 357. *Crotolaria with ſingle, oval, hairy leaves, ſingle pedicles and taper branches.* Crotolaria arboreſcens Africana, Styracis folio. H. L. 170.
9. Crotolaria (*Angulata*) foliis ovatis ſeſſilibus, ramulis angulatis hirſutis, floribus lateralibus ſimpliciſſimis. *Crotolaria with oval leaves ſitting cloſe to the branches, which are angular, hairy, and ſingle flowers proceeding from the ſides of the branches.*
10. Crotolaria (*Laburnifolia*) foliis ternatis ovatis acuminatis, ſtipulis nullis, leguminibus pedicillatis. Flor. Zeyl. 278. *Crotolaria with oval, trifoliate, pointed leaves, no ſtipula, and foot-ſtalks to the pods.* Crotolaria Aſiatica frutеſcens, floribus luteis amplis trifoliata. H. L. 196.
11. Crotolaria (*Alba*) foliis ternis lanceolato-ovatis, caule lævi herbaceo, racemo terminali. Hort. Cliff. 499. *Crotolaria with oval, ſpear-ſhaped, ternate leaves, ſmooth herbaceous ſtalks, which are terminated by looſe ſpikes of flowers.* Anonis Caroliniana perennis non ſpinoſa, foliorum marginibus integris, floribus in thyrſo candidis. Martyn. Cent. 44.

The firſt ſort grows naturally in India. This is an annual plant, which hath an herbaceous four-cornered ſtalk, riſing about two feet high, dividing into three or four branches; theſe have alſo four acute angles, and are garniſhed with oval warted leaves, of a pale green colour, ſtanding on very ſhort foot-ſtalks; the flowers are produced in ſpikes at the end of the branches, which are of the butterfly ſhape, and of a light blue colour, ſucceeded by ſhort turgid pods, which incloſe one row of kidney-ſhaped ſeeds. It flowers in July and Auguſt, and the ſeeds ripen in autumn.

This plant is propagated by ſeeds, which muſt be ſown upon a hot-bed in the ſpring, and when the plants are come up an inch high, they ſhould be tranſplanted to another hot-bed to bring them forward, obſerving to ſhade them from the ſun till they have taken new root; after which they ſhould have free air admitted to them in proportion to the warmth of the ſeaſon, to prevent their being drawn up weak. When the plants have acquired ſtrength in this bed, they ſhould be carefully taken up, with balls of earth to their roots, and each planted in a ſeparate pot, filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, carefully ſhading them till they are rooted again; then they muſt be treated in the ſame manner as other tender exotic plants, giving them proper air and water in warm weather; when the plants are grown ſo tall as to nearly reach the glaſſes of the hot-bed, the pots may be removed into an airy glaſs-caſe, or ſtove, where they may be ſcreened from inclement weather, and have proper air in hot weather; with this treatment the plants will flower in July, and continue to produce freſh ſpikes of flowers till the end of Auguſt; and thoſe ſpikes of flowers which appear early in the ſeaſon, will be ſucceeded by ripe ſeeds in September, ſoon after which the plants will decay.

The ſecond ſort grows naturally at La Vera Cruz in New Spain, from whence the ſeeds were ſent me by the late Dr. Houſtoun; this riſes with a compreſſed winged ſtalk near three feet high, putting out ſeveral ſide branches, garniſhed with ſpear-ſhaped leaves near three inches long, and one broad, covered with ſoft hairs, and ſit cloſe to the branches, alternately; from the foot-ſtalks of each there runs a border or leafy wing, along both ſides of the branches; the flowers are produced in looſe ſpikes at the end of the branches, which are of a pale yellow colour, the ſtandard being ſtretched out a conſiderable length beyond the wings. Theſe are ſucceeded by ſhort turgid pods, which, when ripe, are of a deep blue colour, having one row of ſmall kidney-ſhaped ſeeds, which are of a greeniſh brown colour. This flowers and ſeeds about the ſame time with the former, and requires the ſame treatment.

The third ſort was ſent me from South Carolina by the late Dr. Dale, and alſo from Jamaica by Dr. Houſtoun, ſo that it grows naturally in ſeveral parts of America; this is an annual plant, which riſes with a ſlender ſtalk a foot and a half high, dividing into three or four ſpreading branches, garniſhed with oblong oval leaves ſitting cloſe. The upper part of the branches have two leafy borders or wings, running from one leaf to the other, but the lower part of the branches have none; the foot-ſtalks of the flowers ariſe from the ſide of the ſtalk, thoſe from the lower part of the branches are above a foot long, the upper are about ſix inches, they are very ſlender, and ſuſtain one or two pale yellow flowers at their tops, which are not more than half ſo large as the former ſort, and are ſucceeded by very ſhort turgid pods, in which are incloſed three or four ſmooth kidney-ſhaped ſeeds. This ſort requires the ſame culture as the two former, and flowers at the ſame ſeaſon.

The fourth ſort grows naturally in Jamaica, from whence the ſeeds were ſent me by the late Dr. Houſtoun; this riſes with a ſhrubby taper ſtalk near four feet high, ſending out many ſide branches which are very ſlender, ligneous, and covered with a light brown bark, garniſhed with very narrow ſpear-ſhaped leaves, which are hairy, ſitting cloſe to the branches; the younger ſhoots have a leafy border or wing on two ſides, but the old branches have none; the flowers are produced near the end of the branches, three or four growing alternate on a looſe ſpike; they are of a dirty yellow, and ſmall; the pods which ſucceed them are about an inch long, very turgid, and of a dark blue when ripe. This ſort is propagated by ſeed, which ſhould be ſown on a hot-bed, and the plants treated in the ſame manner as thoſe before; but in autumn they ſhould be placed in the ſtove, where they will live through the winter, and flower early the following ſummer, ſo will perfect their ſeeds very well.

The ſeeds of the fifth ſort were brought me from the coaſt of Malabar, which ſucceeded in the Chelſea garden. This riſes with an angular ſtalk near four feet high, dividing upward into three or four branches, garniſhed with narrow ſpear-ſhaped leaves, placed alternately on very ſhort foot-ſtalks; they are pretty cloſely covered with ſoft ſilvery hairs. The flowers are produced at the end of the branches, in looſe ſpikes; they are large, and of a deep yellow colour, and the ſtyle ſtands out beyond the ſtandard. The flowers are ſucceeded by large turgid pods, containing one row of large kidney-ſhaped ſeeds.

This plant is annual in England, but by the lower part of the ſtalk growing woody, it appears to be of longer duration in the country where it naturally grows; though it will not live through the winter here, for if the plants are placed in a ſtove, the heat is too great for them, and in a green-houſe they are very ſubject to mouldineſs in damp weather. I have ſown the ſeeds of this in the full ground, where the plants have grown upward of three feet high, and have flowered very well, but no pods were formed on theſe; and when they have been treated tenderly, the plants have grown much larger, and produced a greater number of flowers, but theſe have produced no ſeeds. The only way which I could ever obtain any ſeeds, was by raiſing the plants in pots upon hot-beds; and the beginning of July, turning them out of the pots into the full ground on a very warm border under a wall, in which ſituation they flowered very well, and ſome few pods of ſeeds were ripened.

The ſixth ſort was ſent me by the late Dr. Dale from South Carolina, who had the ſeeds ſent him from the country, at a great diſtance from the Engliſh ſettlements. By the deſcription ſent me with the ſeeds, it grows with a ſhrubby ſtalk four or five feet high; but the plants which were raiſed here, periſhed at the approach of winter, ſo that they only flowered, without producing any pods. The ſtalks of this are round, and covered with a light brown bark, garniſhed with ſmooth, oval, heart-ſhaped leaves, which are about four inches long, and near three broad; ſurrounding the ſtalk in ſuch a manner, as if it were run through the middle of the leaves. The flowers grow ſingly, ſitting cloſe to the boſom of each leaf, toward the upper part of the branches; they are of a pale yellow colour, and appear here in Auguſt; but as the plants did not produce any pods, ſo I can give no account of them. This is one of the moſt ſingular plants of the genus I have yet ſeen.

The ſeventh ſort riſes with an herbaceous ſtalk near three feet high, dividing upward into ſeveral branches, garniſhed with oblong leaves, which are narrow at their baſe, but gradually widen to the top, where they are rounded and indented in the middle in the ſhape of a heart; they are of a pale green, and ſmooth. The flowers are produced in ſpikes at the end of the branches, they are pretty large, and of a yellow colour. Theſe appear in July, and the ſeeds ripen in autumn, provided the plants are brought forward in the ſpring, and afterward treated in the ſame manner as hath been directed for the firſt ſort. This grows naturally in the iſland of Ceylon, and is an annual plant, periſhing ſoon after it perfects ſeeds. I received the ſeeds of this plant from the late Dr. Boerhaave, profeſſor at Leyden.

The eighth ſort grows naturally at the Cape of Good Hope, from whence I received the ſeeds. This riſes with a ſhrubby ſtalk about five feet high, dividing into ſeveral branches, garniſhed with roundiſh leaves, ſitting cloſe to the branches; they are of a hoary green, and ſoft to the touch, the branches are taper and ſmooth; the flowers are produced at the end of the branches in looſe ſpikes; they are about the ſize of thoſe of the firſt ſort, and of a fine blue cour. This plant flowers in June and July, and in warm ſeaſons will ripen its ſeeds in autumn. It is propagated by ſeeds, which muſt be ſown upon a good hot-bed in the ſpring, and when the plants are fit to remove, ſhould be each tranſplanted into a ſmall halfpenny pot, and plunged into a hot-bed of tanners bark, and after muſt be treated in the ſame manner as hath been directed for the fourth ſort, placing the plants in a moderate ſtove in winter, otherwiſe they cannot be preſerved in England; the ſecond year the plants will flower, and with proper care their ſeeds will ripen.

The ninth ſort was ſent me from Campeachy, where the plant grows naturally; this riſes with a taper upright ſtalk near three feet high, dividing upward into ſeveral hairy branches, which grow erect, garniſhed with oval ſpear-ſhaped leaves, of a pale green colour; the flowers are produced ſingly from the ſide of the branches, which are of a bright yellow, and are ſucceeded by ſhort turgid pods, having one row of kidney-ſhaped ſeeds. It flowers in July and Auguſt, and with the ſame treatment as hath been directed for the firſt ſort, will perfect ſeeds in autumn. This is an annual plant, which periſhes ſoon after the ſeeds are ripe.

The tenth ſort grows naturally in India; this riſes with a ſhrubby ſtalk four or five feet high, dividing into many branches, garniſhed with ternate oval leaves ending in points; the flowers are large, yellow, growing in large bunches from the ſide of the branches; they appear in July, Auguſt, and September, but I have not ſeen any pods ſucceed them here. However, when the plants are in flower, they make a fine appearance.

It is eaſily propagated by cuttings, during the ſummer months, if the cuttings are planted in pots, and plunged into a moderate hot-bed, being careful to ſhade them till they have taken root, and frequently refreſh them with water: during the months of July, Auguſt, and September, the plants may be expoſed to the open air in a ſheltered ſituation, where they will produce many flowers; but in the autumn they ſhould be placed in a temperate ſtove, to preſerve them in winter.

The eleventh ſort grows naturally in Virginia and Carolina, from both thoſe countries I have received the ſeeds; there are two varieties of this ſpecies, one with a white, and the other a blue flower; but the ſeeds of one will produce both varieties, as I have more than once experienced. The root is perennial, ſending up every ſpring a number of leaves, in proportion to the ſize of the root; the foot-ſtalks of the leaves are ſmooth, riſing two feet high, dividing upward into three or five branches, garniſhed with ternate ſmooth leaves, whoſe lobes are oval, ſpear-ſhaped, and entire; the foot-ſtalks of the flowers ariſe immediately from the root, and advance rather higher than the leaves, being terminated by a thyrſe of large butterfly-ſhaped flowers, near a foot in length; in one variety they are white, and in the other deep blue: theſe are ſucceeded by large ſwelling pods, of a black colour when ripe, having one row of kidney-ſhaped ſeeds. It flowers in June, and the ſeeds ripen in the autumn.

It is propagated by ſeeds, which ſhould be ſown on a moderate hot-bed in the ſpring; when the plants come up they ſhould have free air admitted to them daily, to prevent their drawing up weak, and as ſoon as they are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, plunging them into a moderate hot-bed again, obſerving to ſhade them till they have taken freſh root; then they ſhould be gradually inured to the open air; but in the autumn they ſhould be placed in a common frame, or covered with mats in winter to ſhelter them; but the following ſpring they ſhould be turned out of the pots, and planted in the full ground, where, if the ſoil is dry, and the ſituation ſheltered, they will live many years, producing flowers and ſeeds annually.

As moſt of theſe plants are annual, ſo they require to be brought forward in the ſpring, otherwiſe the ſummers are too ſhort for them to perfect ſeeds; ſo that unleſs they are carefully managed, they will not flower well here; for in general, the ſummers in this country are not very favourable for theſe tender plants. Therefore in order to have theſe tender annual plants in perfection, there ſhould be a low glaſs-caſe erected about five or ſix feet high, which ſhould be made with glaſſes to open or ſlide down on every ſide, as ſhould alſo the top on both ſides, having ſliding glaſſes, that the plants may have ſun and air on every ſide; in this there ſhould be a pit for tanners bark to make a hot-bed, the whole extent, (a particular deſcription of which will be exhibited under the article STOVE) in this hot-bed may be placed all the very curious tender annual plants, where the ſun will conſtantly ſhine on them, ſo long as he makes his appearance above the horizon; and here they may have plenty of free air admitted at all times, when the weather is warm, ſo may be brought to equal perfection, as in the warm countries where they naturally grow; for the warmth of the tan to the roots, and the heat of the ſun through the glaſſes, will in ſummer, be equal to the heat of moſt countries.

Theſe plants naturally grow on ſandy light ſoils, ſo they ſhould always be planted in ſuch; and the pots in which they are planted, muſt not be too large, for in ſuch they will not thrive, ſo that after they have filled the ſmall pots with their roots in which they were firſt planted, they ſhould be ſhaken out of thoſe, and put into penny pots, which will be large enough for moſt of the annual kinds; but thoſe which are of longer duration, will require pots a little larger the following ſpring The waterings of theſe plants ſhould be performed with caution, for too great moiſture will rot the fibres of their roots; ſo that in ſummer, if they are gently watered three or four times a week in hot weather, it will be ſufficient.

CROTON. Lin. Gen. Plant. 960. Ricinoides. Tourn. Inſt. 655. tab. 423. Baſtard Ricinus.

The CHARACTERS are,

It hath male and female flowers in the ſame plant; the flowers have a five-leaved empalement, they have five petals, thoſe of the male being no larger than the leaves of the empalement; the male have five nectarious glands, which are ſmall, and fixed to the receptacle; theſe have ten or fifteen ſtamina, which are joined at their baſe, and terminated by twin ſummits. The female flowers have a roundiſh germen, ſupporting three reflexed ſpreading ſtyles, crowned by bifid reflexed ſtigmas; the germen afterward becomes a roundiſh three-cornered capſule, with three cells, each containing a ſingle ſeed.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Monodelphia. The plants of this claſs and ſection have male and female flowers in the ſame plant, and the male parts are joined in one body.

The SPECIES are,

1. CROTON (*Tinctorium*) foliis rhombeis repandis, capſulis pendulis caule herbaceo. Hort. Upſal. 290. *Croton with rhomboid reflexed leaves, pendulous capſules, and an herbaceous ſtalk.* Ricinoides ex quâ paratur. Tournſol. Gallorum. Tourn. Inſt. 655. *Baſtard Ricinus, from which the Tournſole of the French is made.*
2. CROTON (*Argenteum*) foliis cordato-ovatis ſubtus tomentoſis integris ſubſerratis. Hort. Cliff. 444. *Croton with oval heart-ſhaped leaves, which are entire and woolly.* Ricinoides herbacea, folio ſubrotundo ſerrato fructu parvo conglomerato. Houſt. MSS.
3. CROTON (*Paluſtre*) foliis ovato-lanceolatis plicatis ſerratis ſcabris. Hort. Cliff. 445. *Croton with oval ſpear-ſhaped leaves, which are plaited, ſawed, and rough.* Ricinoides paluſtre, foliis oblongis ſerratis fructu hiſpido. Martyn. Cent. 38.
4. CROTON (*Lobatum*) foliis inermi-ſerratis, inferioribus quinquelobis, ſuperioribus trilobis. Hort. Cliff. 445. *Croton with leaves ſmoothly ſawed, the lower ones having five lobes, and the upper three.* Ricinoides herbacea, foliis trifidis vel quinquefidis & ſerratis. Houſt. MSS.
5. CROTON (*Humile*) tetraphyllum, foliis lanceolatis, acuminatis ſubtus cæſiis, caule herbaceo ramoſo. *Four-leaved Croton with ſpear-ſhaped pointed leaves, gray on their under ſide, and a branching herbaceous ſtalk.* Ricinoides humilis foliis oblongis acuminatis, ſubtus cæſiis. Houſt. MSS.
6. CROTON (*Fruticoſum*) foliis lanceolatis glabris, caule fruticoſo, floribus alaribus & terminalibus. *Croton with ſmooth ſpear-ſhaped leaves, a ſhrubby ſtalk, and flowers growing from the ſides and tops of the branches.* Ricinoides fruteſcens, lauri folio, calyce ampliſſimo viridi. Houſt. MSS.
7. CROTON (*Populi folia*) foliis cordatis, acuminatis, ſubtus tomentoſis, floribus alaribus ſeſſilibus, caule fruticoſo. *Croton with heart-ſhaped pointed leaves, woolly on their under ſide, and flowers growing cloſe to the ſides of the ſtalks, which are ſhrubby.* Ricinoides foliis populi hirſutis. Plum. Cat. 20.
8. CROTON (*Caſcarilla*) foliis lanceolatis acutis integerrimis petiolatis ſubtus tomentoſis, caule arboreo. Amœn. Acad. 5. p. 411. *Croton with ſpear-ſhaped, entire, acute-pointed leaves, woolly on their under ſide, and a tree-like ſtalk.* Ricinoides fruteſcens odorata, foliis anguſtis ſubtus albicantibus. Houſt. MSS. Caſcarilla.
9. CROTON (*Althæafolia*) foliis oblongo-cordatis tomentoſis, caule fruticoſo ramoſo, floribus ſpicatis terminalibus. *Croton with oblong, heart-ſhaped, woolly leaves, a ſhrubby branching ſtalk, and flowers growing in ſpikes at the ends of the branches.* Ricinoides Americana fruteſcens, Althææ folio. Plum. Cat. 20.
10. CROTON (*Salviæ folia*) foliis cordatis acutis, ſubtus tomentoſis, caule fruticoſo, floribus ſpicatis terminalibus & alaribus. *Croton with pointed heart-ſhaped leaves, woolly on their under ſide, a ſhrubby ſtalk, and flowers growing in ſpikes on the tops and ſides of the branches.* Ricinus ſalviæ folio utrinque molli. Pet. Hort. Siec.

The firſt ſort grows naturally in the ſouth of France, from whence I have frequently received the ſeeds; this is an annual plant, which riſes with an herbaceous branching ſtalk about nine inches high, garniſhed with irregular, or rhomboidal figured leaves, which are near two inches long, and one inch and a quarter broad in their wideſt part; theſe ſtand upon ſlender foot-ſtalks, near four inches long. The flowers are produced in ſhort ſpikes from the ſide of the ſtalks, at the end of the branches; the upper part of the ſpike is compoſed of male flowers, having many ſtamina, which coaleſce at the bottom; the lower part hath female flowers, which have each a roundiſh three-cornered germen; theſe afterward become a roundiſh capſule with three lobes, having three cells, each including one roundiſh ſeed. This flowers in July, but unleſs the plants are brought forward in a hot-bed, they do not ripen ſeeds in this country.

The ſeeds of this plant ſhould be ſown in the autumn, ſoon after they are ripe, in a ſmall pot filled with light earth, and plunged into an old tan-bed in a frame, where they may be ſcreened from cold in the winter; and in the ſpring following the pot ſhould be removed to a freſh hot-bed, which will bring up the plants in a month's time; when theſe are grown large enough to remove, they ſhould be each planted in a ſmall pot, and plunged into a freſh hot-bed, being careful to ſhade the glaſſes daily, until the plants have taken new root; then they ſhould have air daily admitted according to the warmth of the ſeaſon, and but little water given to them: with this management I have had the plants flower and produce good ſeeds here, but never could obtain any with other treatment.

This is the plant from which the Tournſole is made, which is uſed for colouring wines and jellies; it is made of the juice which is lodged between the empalement and the ſeeds, which, if rubbed on cloths, at firſt appears of a lively green, but ſoon changes to a bluiſh purple colour; if theſe cloths are put into water, and afterward wrung, they will dye the water to a claret colour; the rags thus dyed, are brought to England, and ſold in the druggiſts ſhops by the name of Tournſole.

The ſecond ſort grows naturally at La Vera Cruz in New Spain, from whence the ſeeds were ſent me by the late Dr. Houſtoun; this is an annual plant, which riſes about a foot high; it hath an angular ſtalk; the branches are naked from their diviſions to the top, where they are garniſhed with a few oval ſpear-ſhaped leaves, which are ſawed on their edges; they are an inch and a half long, and three quarters of an inch broad, ſtanding on foot-ſtalks one inch long. The flowers are produced in cloſe ſhort ſpikes at the end of the branches, thoſe on the upper part being male, and the lower female; they are white, and the male ſoon falls away, but the female are ſucceeded by roundiſh capſules, having three lobes; theſe grow in cloſe cluſters, they have three cells, each containing one roundiſh ſeed. It flowers in July, and the ſeeds ripen in autumn.

The third ſort was diſcovered by the late Dr. Houſtoun at La Vera Cruz, from whence he ſent me the ſeeds; this is alſo an annual plant, which grows naturally in low marſhy grounds, where it hath a very different appearance from what it puts on when ſown upon dry land; thoſe of the watery places have broad flat ſtalks, and leaves three inches long, which are ſcarce a quarter of an inch broad; theſe are rough, and but little indented on their edges; but thoſe plants upon dry ground have oval leaves three inches long, and upwards of two inches broad, which are ſawed on their edges. The flowers are produced at the wings of the leaves, in ſhort looſe ſpikes, having four or five herbaceous male flowers at the top of each, and three or four female flowers at the bottom, which are ſucceeded by roundiſh capſules with three lobes, covered with a prickly huſk; theſe have three cells, each incloſing a ſingle ſeed. It flowers and ſeeds about the ſame time as the former.

The fourth ſort was diſcovered by the ſame gentleman, at the ſame place as the former; this is an annual plant, which riſes with a taper herbaceous ſtalk a foot and a half high, dividing into ſeveral branches, garniſhed with ſmooth leaves, ſtanding upon very long foot-ſtalks, and are for the moſt part placed oppoſite, as are alſo the branches; the lower leaves are divided deeply into five oblong ſegments or lobes, and the upper into three, which are ſlightly ſawed on their edges, ending in acute points. The flowers are produced in looſe ſpikes at the end of the branches, thoſe on the upper part being male, and the lower female, they are of an herbaceous colour; the female flowers are ſucceeded by oblong capſules, having three lobes, which open in three parts, having three cells, each containing one oblong ſeed. This flowers and ſeeds at the ſame time as the former ſorts.

The fifth ſort was found growing naturally at the Havannah, by the late Dr. Houſtoun, who ſent me the ſeeds; this is an annual plant, which rarely grows more than ſix inches high, dividing into two or three branches; the lower part of theſe are garniſhed at each joint with four leaves placed in form of a croſs, two of which are three inches long, and one inch broad near their baſe, ending in acute points; theſe ſtand oppoſite, and the other two leaves between theſe are about two inches long, and a quarter of an inch broad; they are of a light green on their upper ſide, and of a gray or Aſh-colour on their under. The flowers are produced in long looſe ſpikes at the top of the ſtalks, two or three of theſe ſpikes ariſing from the ſame joint; the upper part of theſe ſpikes have male, and the lower female flowers, of an herbaceous colour; the female flowers are ſucceeded by round capſules with three cells, each containing one roundiſh ſeed. This flowers and ſeeds about the ſame time with the former ſorts.

The ſixth ſort was diſcovered by the late Dr. Houſtoun in the iſland of Jamaica, where it grows naturally. It riſes with a ſhrubby ſtalk to the height of ſeven or eight feet, which is covered with an Aſh-coloured bark, and divides into many ſlender branches upward; ſome of theſe branches are terminated by five or ſix ſmaller, which ariſe from the ſame joint; theſe are naked below, but toward their upper part they are garniſhed with ſmooth ſpear-ſhaped leaves, about two inches and a half long, and three quarters of an inch broad, ſtanding on pretty long foot-ſtalks without order; the flowers are produced in ſhort ſpikes at the end of the branches, in the ſame manner as the former; they are of an herbaceous colour, and incloſed in large green empalements.

The ſeventh ſort was ſent me from Jamaica, by Mr. Robert Millar; this riſes with a ſhrubby ſtalk ſeven or eight feet high, ſending out many irregular branches, covered with an Aſh-coloured bark, and garniſhed with heart-ſhaped leaves, near four inches long, and two inches broad in their wideſt part, ending in acute points; they are of a light green on their upper ſide, but woolly on their under, ſtanding on ſlender foot-ſtalks without any order, ſometimes ſingle, and at others, two or three ariſe from the ſame joint. The flowers are produced in ſhort ſpikes from the ſide of the branches; they are of a whitiſh green colour, and the female flowers are ſucceeded by capſules, having three cells, each including a ſingle ſeed.

The eighth ſort grows naturally in Jamaica, from whence the ſeeds were ſent me by the late Dr. Houſtoun; this riſes with a ſhrubby ſtalk about ſix or ſeven feet high, ſending out many ſide branches, which are covered with a ſmooth bark, of a yellowiſh white colour, garniſhed very cloſely with narrow ſtiff leaves near three inches long, and about one eighth of an inch broad, of a light green on their upper ſide, but their under ſide is the ſame colour as the bark; the midrib is furrowed on their upper ſide, and very prominent on the lower; the upper part of the branches divide into four or five ſmaller, which ariſe from the ſame joint, and are nearly equal in their length, and between theſe ariſe a long looſe ſpike of whitiſh green flowers. The whole plant hath an aromatic odour when rubbed. The ſeeds grow in roundiſh capſules having three cells, each including a ſingle ſeed.

The ninth ſort grows naturally in Jamaica, from whence it was ſent me by the late Dr. Houſtoun; this riſes with a ſhrubby ſtalk ſix or ſeven feet high, dividing upward into ſeveral branches, which are covered with a yellowiſh down, garniſhed with long heart-ſhaped leaves, ending in acute points; theſe are two inches and a half long, and one broad in their wideſt part, ſtanding on long foot-ſtalks, covered on both ſides with a woolly down of the ſame colour as the branches. The flowers are produced on long cloſe ſpikes at the end of the branches; the male flowers, which are ſituated on the upper part of the ſpikes, have white flowers of one leaf, divided into five parts almoſt to the bottom, and have five taper ſtamina, ſituated in the bottom. The female flowers on the lower part of the ſpikes, have large woolly empalements, and are ſucceeded by round capſules with three cells, each including a ſingle ſeed.

The tenth ſort riſes with a ſhrubby ſtalk near four feet high, dividing into many ſmaller branches, which have a ſilvery bark, and are garniſhed with ſmall heart-ſhaped leaves, about three quarters of an inch long, and half as broad at their baſe, ending in acute points; theſe are woolly on both ſides, but their under ſide is ſilvery, their upper ſide of a yellowiſh green. The flowers are produced in ſhort ſpikes at the end of the branches, which are ſmall, white, and have woolly empalements. The female flowers on the lower part of the ſpikes are ſucceeded by roundiſh capſules with three cells, each containing one ſeed.

All theſe plants except the firſt, are natives of warm countries, ſo will not thrive in England, unleſs they are tenderly treated. They are all propagated by ſeeds; thoſe which are annual perfect their ſeeds in

England; but the ſhrubby ſorts very rarely arrive to that perfection, ſo their ſeeds muſt be procured from the countries where they naturally grow. The ſeeds muſt be ſown on a hot-bed early in the ſpring, and when the plants are fit to remove, they ſhould be each tranſplanted into a ſmall pot, and plunged into a moderate hot-bed of tanners bark, where they ſhould be ſhaded from the ſun till they have taken freſh root; then they muſt have air admitted to them daily, in proportion to the warmth of the ſeaſon; they muſt alſo be frequently refreſhed with water, particularly the ſecond, third, and fourth ſorts, which will often require water, but the others ſhould have it more ſparingly. After the plants are grown too tall to remain in the frames, they ſhould be removed, either into the ſtove, or a glaſs-caſe, where there is a hot-bed of tanners bark, into which the pots ſhould be plunged, and there the annual ſorts will flower and perfect their ſeeds; but the ſhrubby kinds muſt be removed into the bark-ſtove in the autumn, and during the winter ſeaſon they ſhould have but little water; and the ſtove ſhould be kept in a good temperature of heat, otherwiſe they will not live through the winter in England.

As theſe plants retain their leaves all the year, ſo they make a pretty variety in winter, when they are intermixed with other plants, whoſe leaves are of different forms and colours from theſe.

CROWN IMPERIAL. See PETILIUM.

CRUCIANELLA. Lin. Gen. Plant. 118. Rubeola. Tourn. Inſt. R. H. 130. tab. 50. Petty Madder.

The CHARACTERS are,

The flower hath a two-leaved empalement, which is rigid and compreſſed. It hath one petal, with a ſlender cylindrical tube which is longer than the empalement, and cut into four parts at the brim. It hath four ſtamina ſituated in the mouth of the tube, terminated by ſingle ſummits. It hath a compreſſed germen, ſituated at the bottom of the tube, ſupporting a ſlender bifid ſtyle, crowned by two obtuſe ſtigmas. The germen afterward become two twin capſules, each containing one oblong ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flower having four ſtamina and one ſtyle.

The SPECIES are,

1. CRUCIANELLA (*Anguſtifolia*) erecta, foliis ſenis linearibus. Hort. Upſal. 27. *Upright Crucianella with ſix narrow leaves.* Rubeola anguſtiore folio. Tourn. Inſt. 130. *Petty Madder.*
2. CRUCIANELLA (*Latifolia*) procumbens, foliis quaternis lanceolatis, floribus ſpicatis. Hort. Upſal. 27. *Trailing Crucianella with four ſpear-ſhaped leaves and ſpiked flowers.* Rubeola latiore folio. Tourn. Inſt. 130.
3. CRUCIANELLA (*Maritima*) procumbens ſuffruticoſa foliis quaternis, floribus oppoſitis quinquefidis. Lin. Sp. Plant. 158. *Crucianella with trailing ſhrubby ſtalks, four leaves at each joint, and flowers growing in whorls.* Rubeola maritima. C. B. P.
4. CRUCIANELLA (*Hiſpida*) caule hiſpido, foliis lanceolatis hirſutis oppoſitis, floribus umbellatis terminalibus. *Crucianella with a ſtinging ſtalk, ſpear-ſhaped hairy leaves placed oppoſite, and flowers growing in umbels at the ends of the branches.* Rubeola Americana hirſuta, parietariæ foliis, floribus umbellatis purpureis. Houſt. MSS.
5. CRUCIANELLA (*Americana*) foliis lineari-lanceolatis hirſutis oppoſitis, caule erecto villoſo, floribus ſolitariis alaribus. *Crucianella with narrow, ſpear-ſhaped, hairy leaves placed oppoſite, an erect hairy ſtalk, and ſingle flowers proceeding from the ſides of the branches.*

The firſt ſort grows naturally in the ſouth of France and Italy; this is an annual plant, which riſes with ſeveral upright ſtalks a foot high, having ſix or ſeven very narrow linear leaves placed in whorls, at each joint. The flowers grow in cloſe ſpikes at the top and from the ſide of the branches; theſe are ſmall, white, and not longer than the empalement, ſo make no great appearance. It flowers in June and July, and the ſeeds ripen in autumn.

The ſecond ſort grows in the iſlands of the Archipelago, and alſo about Montpelier; this is alſo an annual plant, ſending out ſeveral branching ſtalks from the root, which lie proſtrate, and are garniſhed with four ſpear-ſhaped leaves at each joint. The flowers are produced in long ſpikes at the extremity of the branches; theſe are very ſmall, ſo make no great appearance. It flowers about the ſame time as the former.

The third ſort is like the ſecond in the appearance of leaves and ſtalks, but the flowers grow on the ſide of the ſtalks, almoſt in whorls, and make little appearance. This grows naturally on the borders of the ſea, in the ſouth of France and Italy.

Theſe three ſorts are preſerved in ſome gardens for the ſake of variety; if the ſeeds are ſown on a bed of light earth early in the ſpring, where they are deſigned to remain, they will require no other culture, but to thin them where they are too cloſe, and keep them clean from weeds; or if the ſeeds are permitted to ſcatter, the plants will come up in the ſpring, and require no other treatment; but the third ſort will not ripen its ſeeds here, when the autumn is not favourable.

The fourth ſort hath four-cornered, rough, prickly ſtalks, which bend downward, and are garniſhed with ſpear-ſhaped leaves, which are hairy and ſtand oppoſite; the flowers are produced in ſmall cluſters at the end of the branches, which are blue, and cut into four parts at the top; after theſe decay, they are ſucceeded by twin capſules joined, in each of theſe is one oblong ſeed.

The fifth ſort riſes with a ſhrubby branching ſtalk near three feet high, which is garniſhed with narrow ſpear-ſhaped leaves, covered with ſtinging hairs. The flowers are produced from the wings of the leaves, on each ſide the ſtalk ſingly; theſe are of a pale blue colour, and are ſucceeded by twin fruit like the former.

Both theſe ſorts grow naturally at La Vera Cruz in New Spain, from whence the ſeeds were ſent me by the late Dr. Houſtoun; and the plants grew in the Chelſea garden very well during the ſummer ſeaſon, but periſhed in the autumn before their ſeeds were ripe.

CRUCIATA. See VALANTIA.

CRUPINA BELGARUM. See SERRATULA.

CUCUBALUS. Lin. Gen. Plant. 502. Tourn. Inſt. R. H. 339. tab. 176. Berry-bearing Chickweed.

The CHARACTERS are,

The flower hath an oblong permanent empalement of one leaf, cut into five ſegments. It hath five petals, with tails as long as the empalement, but ſpread open at the top. It hath ten ſtamina, five of which are alternately inſerted in the tail of the petals; theſe are terminated by oblong ſummits. In the center is ſituated the oblong germen, ſupporting three ſtyles which are longer than the ſtamina, crowned by oblong hairy ſtigmas. The empalement afterward becomes a pointed cloſe capſule with three cells, opening at the top in five parts, and filled with many roundiſh ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's tenth claſs, intitled Decandria Trigynia, the flowers having ten ſtamina and three ſtyles.

The SPECIES are,

1. CUCUBALUS (*Bacciferus*) calycibus campanulatis, petalis diſtantibus, pericarpiis coloratis, ramis divaricatis. Lin. Sp. Plant. 414. *Cucubalus with a bell-ſhaped empalement, petals ſtanding aſunder, a coloured cover to the fruit, and divaricated branches.* Cucubalus Plinii. Lugd. 1429.
2. CUCUBALUS (*Latifolius*) caulibus erectis glabris, calycibus ſubgloboſis, ſtaminibus corollâ longioribus. *Cucubalus with ſmooth erect ſtalks, globular empalements, and ſtamina longer than the petals.* Lychnis ſylveſtris quæ behen album vulgò. C. B. P. 205. *Commonly called Spatling Poppy.*
3. CUCUBALUS (*Anguſtifolius*) calycibus ſubgloboſis, caule ramoſo patulo, foliis linearibus acutis. *Cucubalus with globular empalements, a branching ſpreading ſtalk,*

and narrow-pointed leaves. Lychnis ſylveſtris quæ behen album vulgò, foliis anguſtioribus & acutioribus. C. B. P. 250. *Spatling Poppy, with narrower pointed leaves.*

4. Cucubalus (*Behen*) calycibus ſubgloboſis glabris reticulato-venoſis, capſulis trilocularibus corollis ſubnudis. Flor. Suec. 360. *Cucubalus with ſmooth globular empalements which have netted veins, capſules having three cells, and naked petals.* Lychnis Suecica behen album folio, habitu, calyce ampliſſimo: gumſepungar ſive ſcrotum arietis dicta. Boerh. Ind. alt. 212. *Called Gumſepungar in Sweden.*

5. Cucubalus (*Fabarius*) foliis obovatis carnoſis. Prod. Leyd. 448. *Cucubalus with oval fleſhy leaves.* Lychnis maritima ſaxatilis, folio anacampſerotis. Tourn. Cor. 24.

6. Cucubalus (*Dubrenſis*) floribus lateralibus decumbentibus, caule indiviſo, foliis baſi reflexis. Lin. Sp. Plant. 414. *Cucubalus with declining flowers on the ſides of the ſtalk, which is undivided, and leaves reflexed at their baſe.* Lychnis major noctiflora Dubrenſis perennis. Raii Hiſt. 995. *Greater perennial night-flowering Lychnis of Dover.*

7. Cucubalus (*Stellatus*) foliis quaternis. Hort. Upſal. 110. *Four-leaved Cucubalus.* Lychnis carophyllæus Virginianus, gentianæ foliis glabris quatuor ex ſingulis geniculis caulem amplexantibus, flore amplo fimbriato. Raii Hiſt. 1895.

8. Cucubalus (*Noctiflora*) calycibus ſtriatis acutis petalis bipartitis, caule paniculato, foliis linearibus. *Cucubalus with ſtriated acute empalements, petals divided in two parts, a paniculated ſtalk, and narrow leaves.* Lychnis noctiflora anguſtifolia odorato. Tourn. Inſt. R. H. 335. *Narrow-leaved, ſweet-ſcented, night-flowering Lychnis.*

9. Cucubalus (*Otites*) floribus dioicis, petalis linearibus indiviſis. Hort. Cliff. 272. *Cucubalus with male and female flowers on different plants, and linear undivided petals.* Lychnis viſcoſa, flore muſcoſo. C. B. P. 206.

10. Cucubalus (*Acaulis*) acaulis. Flor. Lapp. 184. *Cucubalus without ſtalks.* Lychnis Alpina pumila, folio gramineo, ſive muſcus Alpinus Lychnidis flore. C. B. P. 206.

11. Cucubalus (*Catholicus*) petalis bipartitis, floribus paniculatis, ſtaminibus longis, foliis lanceolato ovatis. Hort. Upſal. 111. *Cucubalus with bifid petals, flowers growing in panicles, long ſtamina, and ſpear-ſhaped acute leaves.* Lychnis altiſſima, ocymaſtri facie, flore muſcoſo. Triumfet.

12. Cucubalus (*Paniculatus*) foliis radicalibus ovatis acutis, caulinis lanceolatis oppoſitis, floribus paniculatis erectis. *Cucubalus with lower leaves oval and pointed, thoſe on the ſtalks ſpear-ſhaped, oppoſite, and flowers growing in panicles which are erect.*

13. Cucubalus (*Italicus*) petalis bipartitis, caule paniculato, foliis radicalibus ovato-lanceolatis caulinis linearibus. *Cucubalus with petals divided in two parts, a paniculated ſtalk, whoſe lower leaves are oval and ſpear-ſhaped, and thoſe on the ſtalks very narrow.*

The firſt ſort grows naturally in France, Germany, and Italy, in ſhady places, and is ſeldom kept in gardens, unleſs for the ſake of variety; it ſends out many climbing ſtalks, which grow four or five feet high where they meet with ſupport, otherwiſe they trail on the ground; theſe ſtalks ſend out ſide branches oppoſite, at each joint; the leaves are like thoſe of Chickweed, and are placed oppoſite. The flowers come out ſingle at the end of the branches, which have large inflated empalements; they conſiſt of five petals, which are white, cut at the brim into ſeveral narrow ſegments, and are placed at a diſtance from each other; they are ſucceeded by oval berries, which, when ripe, are black and full of juice, incloſing ſeveral flat ſhining ſeeds. It flowers in June, and the ſeeds ripen in autumn. This hath a perennial creeping root, whereby it is apt to multiply too faſt in gardens. It delights in ſhade, and will thrive in almoſt any ſoil.

The ſecond ſort grows naturally in moſt parts of England, where it is generally called Spatling Poppy. This ſtands in the catalogue of medicinal plants, under the title of Behen album; the roots of it are ſometimes uſed, and are accounted cordial, cephalic, and alexipharmic. It hath a perennial root, which ſtrikes deep into the ground, ſo that they are not eaſily deſtroyed by the plough, therefore it is frequently ſeen growing in bunches among corn. It is a rambling weed, ſo is ſeldom cultivated.

The third ſort grows naturally on the Alps; this differs from the former, in having much longer and narrower leaves, and the ſtalks being more divided and ſpreading, nor do the roots creep under ground like that. Theſe differences are conſtant, for I have ſown it above thirty years, and never found it vary.

The fourth ſort grows naturally in Sweden, and ſome other northern countries, where it paſſes for the common ſort; but although it is there ſo, yet is very different from the ſecond here mentioned, which is the ſort that grows common in moſt other parts of Europe. The ſtalks of this are much larger, the leaves longer and more pointed; the empalement of the flower is curiouſly veined like net-work, of a purpliſh colour, whereas that of our common ſort is plain. Theſe differences are laſting, when the plants are cultivated in a garden.

The fifth ſort was diſcovered by Tournefort in the Levant, who ſent the ſeeds to the royal garden at Paris. This puts out many oval, thick, ſucculent leaves near the ground, out of the middle of which, ariſes an upright ſtalk about fifteen inches high, the lower part of which is garniſhed with leaves of the ſame form and conſiſtence as thoſe at bottom, but are ſmaller; theſe are placed oppoſite; the upper part of the ſtalk divides into two ſmaller, on which ſtand a few ſmall herbaceous flowers at each joint. It flowers in June, and ſometimes ripens ſeeds in autumn. The plant is biennial, generally periſhing when it has produced ſeeds; but unleſs it is ſown upon a very dry rubbiſh, and in a warm ſituation, the plants will not live through the winter in England; for when they are in good ground, they grow large, and are ſo replete with moiſture, as to be affected by the firſt froſt in the autumn; but where they have grown upon an old wall, I have known them eſcape, when all thoſe were killed which grew in the ground.

The ſixth ſort grows naturally upon the cliffs near Dover. This hath a perennial root, from which ariſes a ſingle ſtalk about a foot and a half high, garniſhed with long narrow leaves placed oppoſite; the flowers are produced from the ſide of the ſtalks, each foot-ſtalk ſuſtaining three flowers; the foot-ſtalks come out by pairs oppoſite, the empalement of the flower is long and ſtriped, the flowers are of a pale red. Theſe appear in June, and the ſeeds ripen in autumn.

The ſeventh ſort grows naturally in Virginia, and ſeveral other parts of North America. This hath a perennial root, from which ariſe two or three ſlender upright ſtalks about a foot high, their lower part being garniſhed with four leaves at each joint, placed in form of a croſs; theſe are ſmooth, of a deep green, about an inch and a half long, and half an inch broad near their baſe, terminating in acute points; the joints of the upper part of the ſtalk are garniſhed with white fringed flowers, ſtanding ſingle upon pretty long foot-ſtalks, which come out by pairs oppoſite. The flowers appear in June, and in warm ſeaſons the ſeeds will ripen in England.

The eighth ſort grows naturally in Spain and Italy. This is a perennial plant, which riſes with an upright branching ſtalk a foot and a half high, garniſhed with very narrow leaves placed oppoſite; the upper part of the ſtalk is very branching; ſome of theſe branches are long, and others ſhort; the flowers ſtand upon long naked foot-ſtalks, each ſupporting three or four flowers, which have long tubes, with ſtriped empalements; the petals are large, and deeply divided at the top; they are of a pale bluiſh colour. Theſe flowers are cloſed all day, but when the ſun leaves them, they expand, and then they have a very agreeable ſcent. This ſort may be propagated by ſeeds, which ſhould be ſown in the ſpring upon a bed of light earth; and when the plants are fit to remove, they ſhould be planted in a nurſery-bed, at about four inches diſtance, where they may remain till autumn, when they may be planted in the borders of the flower-garden, where they are deſigned to remain. The following ſummer theſe will produce their flowers, and ripen their ſeeds in the autumn; but the roots will continue ſeveral years, provided they are not planted in rich ground, where they are very ſubject to rot in winter.

The ninth ſort grows naturally in Auſtria, Sileſia, and Italy, as alſo in ſome parts of England. This is male and female in different plants; it hath a thick, fleſhy, biennial root, which ſtrikes deep in the ground, ſending out many oblong leaves, which are broad at their extremity, but contract narrower to their baſe; from between theſe ariſe the ſtalks, which in the male plants often grow four or five feet high, but thoſe of the female are ſeldom above three feet high; the ſtalks are garniſhed with narrow leaves, placed oppoſite at each joint, where there exſudes a viſcous clammy juice, which ſticks to the fingers when handled, and the ſmall inſects which ſettle upon thoſe parts of the ſtalks, are thereby faſtened ſo as not to get looſe again. The flowers of the male plants are produced in looſe ſpikes from the lower joints of the ſtalk, but on the upper part, they ſtand on ſingle foot-ſtalks in cluſters quite round the ſtalks; theſe are ſmall, of a greeniſh colour, and have each ten ſtamina. The female plants have three or four flowers growing upon each foot-ſtalk, which ariſe from the ſide of the ſtalk. Theſe are ſucceeded by oval ſeed-veſſels, containing many ſmall ſeeds; they flower in June, and the ſeeds ripen in autumn. This is propagated by ſeeds, which ſhould be ſown where the plants are deſigned to remain; for as they ſend out long tap-roots, they do not bear tranſplanting, unleſs it is performed while the plants are young. The plants are very hardy, ſo will thrive in almoſt any ſoil or ſituation, but agree beſt with a dry ſoil. It is neceſſary to have ſome male plants among the female, to have perfect ſeeds.

The tenth ſort grows naturally on the Alps, and alſo upon the hills in the north of England and Wales. This is a very low plant, with ſmall leaves, which ſpread on the ground, and have the appearance of moſs. The flowers are ſmall, erect, and rarely riſe more than half an inch high; they are of a dirty white colour, and appear in May. This is a perennial plant, which will not thrive but in a moiſt ſoil and a ſhady ſituation.

The eleventh ſort grows naturally in Italy and Sicily. This is a perennial plant, with large thick roots, ſending out many long ſpear-ſhaped leaves near the ground; between theſe ariſe round viſcous ſtalks, which grow three feet high, garniſhed at each joint by two long narrow leaves, ending in acute points. The ſtalks branch out into many diviſions, on the upper parts of which the foot-ſtalks of the flowers ariſe from each joint by pairs oppoſite; each of theſe ſuſtain three or four flowers of an herbaceous colour, whoſe petals are divided into two parts; the flowers appear in June, and the ſeeds ripen in the autumn. This is propagated by ſeeds in the ſame manner as the ninth.

The twelfth ſort grows naturally in Spain and Italy, from whence I received the ſeeds. This is a biennial plant, which decays ſoon after it hath perfected ſeeds: this hath many oval pointed leaves near the root, ſtanding upon long foot-ſtalks; between theſe ariſe an upright ſtalk, ſending out two ſide branches at each joint, placed oppoſite; under each of theſe is ſituated one ſpear-ſhaped leaf, ending in an acute point; theſe ſide branches, and alſo the upright ſtalks, are terminated by whitiſh flowers, formed into a panicle, and ſtanding erect; theſe appear in June, and are ſucceeded by ſeeds which ripen in autumn. This is propagated by ſeeds, which may be ſown on an open border where the plants are deſigned to remain, and require no other culture but to keep them clear from weeds.

The thirteenth ſort grows naturally in Italy, from whence I received the ſeeds; this is a perennial plant, which hath many oval ſpear-ſhaped leaves near the root; the ſtalks riſe about two feet high; they are viſcous, and from each joint comes out two ſide branches, under which are ſituated two very narrow leaves; the ſtalks ſpread out and form a ſort of panicle, and are terminated by cluſters of greeniſh flowers, whoſe petals are divided into two parts. This flowers in June, and the ſeeds ripen in autumn. It is propagated in the ſame manner as the ninth ſort, and requires the ſame treatment.

CUCULLATE PLANTS are ſo called, of cuculla, *Lat.* a hood or cowl, ſuch as monks wear, becauſe their flowers reſemble it.

CUCUMIS. Lin. Gen. Plant. 969. Tourn. Inſt. R. H. 104. tab. 28. Cucumber; in French, *Concombre.*

The CHARACTERS are,

It hath male and female flowers placed at diſtances on the ſame plant; theſe have a bell-ſhaped empalement of one leaf, whoſe border is terminated by five briſtles. The flowers are bell-ſhaped, have one petal which adheres to the empalement, and is cut into five oval rough ſegments. The male flowers have three ſhort ſtamina, which are inſerted to the empalement, two of which have bifid tops. Theſe are terminated by very narrow ſummits or lines, which run upward and downward, and adhere to the outſide. The female flowers have no ſtamina, but have three ſmall pointed filaments without ſummits. The germen, which is oblong, is ſituated under the flower, ſupporting a ſhort cylindrical ſtyle, crowned by three thick convex ſtigmas, which are bipartite. The germen afterward becomes an oblong fleſhy fruit with three cells, including many oval, flat, pointed ſeeds.

This genus of plants is ranged in the tenth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Syngeneſia. The plants of this claſs have male and female flowers on different parts of the ſame plant, and thoſe of this ſection have their ſtamina joined. To this genus he has joined the Melon, Water Melon, and Bitter Apple; but however theſe may agree in their characters, ſo as to be joined together in a ſyſtem of botany, it will not be proper in a book of gardening to be followed.

The SPECIES are,

1. CUCUMIS (*Sativus*) foliorum angulis rectis, pomis oblongis ſcabris. Hort. Cliff. 451. *Cucumber with leaves having right angles, and an oblong rough fruit.* Cucumis ſativus vulgaris. C. B. P. 310. *The common Garden Cucumber.*
2. CUCUMIS (*Flexuoſus*) foliorum angulis rectis, pomis longiſſimis glabris. *Cucumber with leaves having right angles, and a very long ſmooth fruit.* Cucumis flexuoſus. C. B. P. 310. *The long Turkey Cucumber.*
3. CUCUMIS (*Chata*) hirſutis foliorum angulis integris dentatis, pomis fuſciformibus hirtis utrinque attenuatis. Haſſelq. It. 491. *Hairy Cucumber with angular indented leaves, and narrow hairy fruit.* Cucumis Ægyptius rotundifolius. C. B. P. 310.

The firſt ſort is the Cucumber which is generally cultivated for the table, and is ſo well known as to need no deſcription. The ſecond ſort is the long Turkey Cucumber, which is alſo pretty well known in England. The ſtalks and leaves of this ſort are much larger than thoſe of the common ſort. The fruit is generally twice the length, and hath a ſmooth rind: this is undoubtedly different from the common ſort, for I have cultivated it above forty years, and have not found it alter. There are green and white fruit of this ſort, which differ but little except in their colour, ſo I have not diſtinguiſhed them as diſtinct ſpecies, though I have alſo found them keep their difference from ſeeds. The white is leſs watery than the green, ſo is generally better eſteemed. I have alſo received ſeeds from China of another ſort, with a much longer fruit than the Turkey, but I have found this will degenerate in time, and become more like the common ſort.

In Holland they cultivate a long white prickly Cucumber only, which is very different from the Turkey Cucumber, being near as rough as the common ſort; but this is not ſo hardy as our common ſort, ſo is ſeldom cultivated in England; but the fruit is not ſo watery or full of ſeeds as the common, therefore is preferable to it for the table.

The third ſort here enumerated is rarely cultivated, but in botanic gardens for the ſake of variety, the fruit being very indifferent, and the plants being tender, require a good heat to bring them to perfection in England; theſe plants ramble very far, ſo muſt have much room, and they are not very fruitful.

The common ſort is cultivated in three different ſeaſons, the firſt of which is on hot-beds under garden-frames, for early fruit; the ſecond is under bell or hand-glaſſes, for the middle crop; and the third is in the common ground, for a late crop, or to pickle.

I ſhall begin with giving directions for raiſing Cucumbers early, which is what moſt gentlemens gardeners have an emulation to excel each other in; and ſome have been at the pains and expence to have ripe fruit in every month of the year, which is rather a curioſity than any real advantage; for Cucumbers that are produced before April, cannot be ſo wholeſome as thoſe that are later; for before the ſun hath ſtrength enough to warm the beds through the glaſſes in the day-time, all the heat muſt proceed from the fermentation of the dung, which muſt conſequently occaſion a very conſiderable ſteam, as alſo a great quantity of air will be thereby generated, which, being pent up in the hot-bed, ſoon becomes rancid; and the ſteam of the bed being by the cold of the night condenſed into large drops of water, theſe, being abſorbed or inſpired by the plants, muſt certainly make the fruit crude and unwholeſome, eſpecially when the nights are very long. This, together with the great expence and trouble of procuring them earlier, having in ſome meaſure got the better of peoples ambition, ſo this is leſs practiſed than it hath been ſome years ſince; but as there are many perſons who yet value themſelves on their ſkill in raiſing early Cucumbers, we may probably be cenſured, as being deficient in what they call an eſſential part of gardening, ſhould we omit the method practiſed for raiſing theſe fruit early in the year. Therefore ſhall proceed to give ſuch directions, as if carefully attended to, will not fail of ſucceſs.

Thoſe perſons who are very deſirous to be early with their Cucumbers, generally ſow their ſeeds before Chriſtmas, but the generality of gardeners commonly put their ſeeds into the hot-bed about Chriſtmas. Where perſons have the conveniency of a ſtove for raiſing theſe plants, it is attended with leſs trouble than a common hot-bed, and is a much ſurer method, becauſe the plants will have a much greater ſhare of air, which will alſo be leſs mixed with damp or rancid vapours; for by the heat of the fires theſe will be diſſipated, and the temperature of the air is kept more equal than can be done with all poſſible care in a hot-bed, at a ſeaſon when we enjoy but little ſun; therefore where there is this convenience, the ſeeds ſhould be ſown in ſmall pots, filled with light dry earth, and plunged into the tan-bed, in the warmeſt part of the ſtove. The pots with earth ſhould be plunged three or four days before the ſeeds are ſown, that the earth may be properly warmed to receive them; the ſeeds ſhould be at leaſt three or four years old, but if it is more, provided it will grow, it will be the better. If the ſeeds are good, the plants will begin to appear in about a week or nine days, at which time there muſt be as many halfpenny pots filled with dry light earth, as there are plants deſigned for planting (always allowing for loſs; ſo that where twenty-four plants are wanting, there ſhould be thirty raiſed); theſe pots ſhould be plunged into the bark-bed, that the earth may be warmed to receive the plants, which ſhould be pricked into theſe pots as ſoon as the two firſt leaves are raiſed above ground; into each of theſe pots may be two plants pricked, but when they have taken root, and are ſafe, the worſt ſhould be drawn out, being careful not to diſturb the roots of thoſe which are left. In the management of theſe plants, there muſt be great care taken not to give them too much water; and it will be very proper to put the water into the ſtove ſome hours before it is uſed, that the cold may be taken off; but there muſt be caution uſed not to make it too warm, for that will deſtroy the plants; they muſt alſo be guarded from the moiſture which frequently drops from the glaſſes of the ſtove, which is very deſtructive to theſe plants while young. As theſe plants muſt not be kept too long in the ſtove leſt they become troubleſome to the other plants, there ſhould be a proper quantity of new dung prepared for making a hot-bed to receive them; this muſt be in proportion to the quantity of holes or plants intended: for a middling family ſix or nine lights of Cucumbers will be ſufficient, and for a large one double the quantity; but the beds where they are deſigned to remain need not be made ſo ſoon, but rather a ſmall bed of one light, in which the plants may be trained up, till they have acquired a greater ſhare of ſtrength; and for this bed one good cart load of dung will be ſufficient. This ſhould be new, and not too full of ſtraw, nor ſhould it want a proper portion; it ſhould be well mixed together and thrown in a heap, mixing ſome ſea-coal aſhes with it; after it hath lain in a heap a few days, and has fermented, it ſhould be carefully turned over and mixed, laying it up again in a heap; and if there is a great ſhare of ſtraw in it, there may be a neceſſity for turning it over a third time, after having laid a few days: this will rot the ſtraw and mix it thoroughly with the dung, ſo there will be leſs danger of its burning afterward when the bed is made, which ſhould be done when the dung is in proper order. The place where the hot-bed is made ſhould be well ſheltered by Reed hedges, and the ground ſhould be dry; then there ſhould be a trench made in the ground, of a proper length and breadth, and a foot deep at leaſt; into which the dung ſhould be wheeled and carefully ſtirred up and mixed, ſo that no part of it ſhould be left unſeparated, for where there is not this care taken, the bed will ſettle unequally; there ſhould alſo be great care taken to beat the dung down cloſe in every part of the bed alike. When the bed is made, the frame and glaſſes ſhould be put upon it to keep out the rain, but there ſhould be no earth laid upon the dung till two or three days after, that the ſteam of the dung may have time to evaporate. If there ſhould be any danger of the bed burning, it will be proper to lay ſome ſhort old dung, or ſome neats dung, over the top of the hot dung about two inches thick, which will keep down the heat, and prevent the earth from being burnt; after this there ſhould be a ſufficient number of three farthing pots placed upon the bed, filled with light dry earth, and all the interſtices between them filled up with any common earth. In two or three days the earth in theſe pots will be of a proper temperature of warmth to receive the plants, which ſhould be then turned out of the halfpenny pots, preſerving the ball of earth to their roots, and planted into the three farthing pots, filling up the pots with good earth; then a little water ſhould be given them to ſettle the earth about their roots, being careful not to give them too much wet; and as theſe will have ſuch large balls of earth to their roots, they will not feel their movement, therefore will not require ſhading from the ſun; but the glaſſes ſhould be raiſed up a little on the contrary ſide from the wind, to let the ſteam of the bed paſs off; and they ſhould alſo be frequently turned in the day-time, that the wet occaſioned by the ſteam of the dung may be dried, otherwiſe the moiſture will fall on the plants, which will be very injurious to them. If the bed ſhould heat too violently, ſo as to endanger ſcalding the roots of the plants, the pots may be raiſed ſo as to allow of a little hollow at their bottoms, which will effectually prevent injury thereby; and when the heat declines, the pots may be ſettled down again. The glaſſes of the hot-bed ſhould be well covered with mats every night, to keep the bed in a proper temperature of heat, and great care muſt be taken to admit freſh air every day to the plants; but this ſhould be done with caution, ſo as to guard againſt the cold winds which uſually blow at that ſeaſon; ſo that a mat or canvaſs ſhould be hung over the opening made by raiſing of the glaſſes, to prevent the cold air from ruſhing in too violently, and the glaſſes ſhould always be raiſed on that ſide which is contrary to the wind. The plants will alſo require to be frequently watered, but it muſt be cautiouſly given them at this ſeaſon, and the water ſhould not be cold, but either placed in a ſtove, or put into a warm heap of dung, to take off the chill from it before it is uſed.

If the weather ſhould prove bad, and the heat of the bed decline, there ſhould be ſome hot dung laid round the ſides of the bed to renew the heat, which muſt not be ſuffered to fail; for as the plants have been tenderly brought up, they muſt not ſuffer from cold, for that will ſoon deſtroy them.

In this bed the plants may remain about three weeks or a month, in which time, if they have been properly managed, they will have obtained ſufficient ſtrength to put out for good; therefore a proper quantity of dung ſhould have been mixed and turned ready for making of the beds. The uſual quantity allowed for making of the beds at this ſeaſon, is one good cart load to each light: this ſhould be well mixed and turned over in the manner before directed; then a trench ſhould be dug in the ground the length and width of the intended bed, into which the dung ſhould be wheeled, and properly worked according to the above directions, and ſome old dung or neats dung ſpread over the top. The frames and glaſſes ſhould then be put on the bed, which ſhould be raiſed every day to let the ſteam of the dung paſs off, and in about three days the bed will be in a proper temperature of heat to receive the plants; at which time the dung ſhould be covered over with dry earth about four inches thick, and in the middle of the bed it ſhould be three or four inches thicker; this ſhould be laid upon the dung at leaſt twenty-four hours before the plants are removed into the bed, that the earth may be properly warmed; then the plants ſhould be carefully ſhaken out of the pots, preſerving all the earth to their roots, and placed on the top of the earth in the middle of the bed. Two, or at moſt, three of theſe plants will be ſufficient for each light, and theſe ſhould be placed at about ſeven or eight inches aſunder, not all the roots together, as is too often practiſed. When the plants are thus ſituated in the bed, the earth which was laid ſo much thicker in the middle of the bed, ſhould be drawn up round the ball which remained to the roots of the plants, into which their roots will ſoon ſtrike; there ſhould always be a magazine of good earth laid under cover to keep it dry, for the earthing of theſe beds; for if it is taken up wet, it will chill the beds, and alſo occaſion great damps therein, therefore it is quite neceſſary to have a ſufficient quantity of earth prepared long before it is uſed. When the plants are thus ſettled, they muſt have proper air and water, according as they may require, being careful not to admit too much cold air, or give too much water; the glaſſes ſhould alſo be well covered with mats every night, to keep up the warmth of the bed, and ſome freſh earth ſhould be put into the bed at different times, which ſhould be laid at ſome diſtance from the roots of the plants till it is warmed, and then ſhould be drawn up round the heap of the earth in which the plants grow, to increaſe the depth; this ſhould be raiſed to the full height of the former ball, that the roots of the plants may more eaſily ſtrike into it: by this method of ſupplying the earth, the whole ſurface of the beds will be covered nine or ten inches with earth, which will be of great ſervice to the roots of the plants; for where the earth is very ſhallow, the leaves of the plants will always hang in the heat of the day, unleſs they are ſhaded, and the plants will require more water to keep them alive, than is proper to give them; therefore it will be found much the better way to allow a proper depth of earth to the beds: but the reaſon of not laying the quantity of earth on the bed when it is firſt made, is, that the dung ſhould not be too much chilled by it, or that the earth may not be burned, which might be endangered thereby, were the whole thickneſs to be laid on at once; beſides, by thus gradually applying the earth, it will be freſh, and much better for the roots of the plants, than that which has been long upon the bed, and has been too much moiſtened by the ſteam ariſing from the dung.

If the heat of the bed ſhould decline, there ſhould be ſome hot dung laid round the ſide of the bed to renew the heat; for if that ſhould fail at the time when the fruit appears, they will fall off and periſh, therefore this muſt be carefully regarded; and when the plants have put out ſide branches (which the gardeners call runners) they ſhould be properly placed, and pegged down with ſmall forked ſticks to prevent their riſing up to the glaſſes, and alſo from croſſing and entangling with each other; ſo that when they are properly directed at firſt, there will be no neceſſity of twiſting and tumbling the plants afterward, which is always hurtful to them.

When the earth of the bed is laid the full thickneſs, it will be neceſſary to raiſe the frames, otherwiſe the glaſſes will be too cloſe to the plants; but when this is done, there muſt be care taken to ſtop the earth very cloſe round the ſide of the frame, to prevent the cold air from entering under them. The watering the plants, and admitting freſh air to them, muſt be diligently attended to, otherwiſe the plants will be ſoon deſtroyed; for a little neglect either of admitting air, or letting in too much, or by over watering, or ſtarving the plants, will very ſoon deſtroy them paſt recovery.

When the fruit appears upon the plants, there will alſo appear many male flowers on different parts of the plant; theſe may at firſt ſight be diſtinguiſhed, for the female flowers have the young fruit ſituated under the flowers, but the male have none; but theſe have three ſtamina in their center with their ſummits, which are loaded with a golden powder. This is deſigned to impregnate the female flowers, and when the plants are fully expoſed to the open air, the ſoft breezes of wind convey this farina or male powder from the male to the female flowers; but in the frames where the air is frequently too much excluded at this ſeaſon, the fruit often drops off for want of it; and I have often obſerved, that bees that have crept into the frames when the glaſſes have been raiſed to admit the air, have ſupplied the want of thoſe gentle breezes of wind, by carrying the farina of the male flowers on their hind legs into the female flowers, where a ſufficient quantity of it has been left to impregnate them. For as the bees make their wax of the farina or male powder of flowers, they ſearch all the flowers indifferently to find it; and I have obſerved them come out of ſome flowers with their hind legs loaded with it, and going immediately into other flowers which have none, they have ſcattered a ſufficient quantity of this farina about the ſtyle of the female flowers, to impregnate and render them prolific. Theſe inſects have taught the gardeners a method to ſupply the want of free air, which is ſo neceſſary for the performance of this in the natural way. This is done by carefully gathering the male flowers, at the time when this farina is fully formed, and carrying them to the female flowers, turning them down over them, and with the nail of one finger, gently ſtriking the outſide of the male, ſo as to cauſe the powder on the ſummits to ſcatter into the female flowers, and this is found to be ſufficient to impregnate them; ſo that by practiſing this method, the gardeners have now arrived at a much greater certainty than formerly, to procure an early crop of Cucumbers and Melons; and by this method the floriſts have arrived to greater certainty of procuring new varieties of flowers from ſeeds, which is done by the mixing of the farina of different flowers into each other.

When the fruit of the Cucumbers are thus fairly ſet, if the bed is of a proper temperature of warmth, they will ſoon ſwell, and become fit for uſe; ſo all that is neceſſary to be obſerved, is to water the plants properly, which ſhould be done by ſprinkling the water all over the bed, for the roots of the plants will extend themſelves to the ſide of the bed; therefore thoſe who are inclined to continue theſe plants as long as poſſible in vigour, ſhould add a ſufficient thickneſs of dung and earth all round the ſides of the beds, ſo as to enlarge them to near double their firſt width; this will ſupply nouriſhment to the roots of the plants, whereby they may be continued fruitful great part of the ſummer; whereas, when this is not practiſed, the roots of the plants, when they have reached the ſide of the beds, are dried by the wind and ſun, ſo that the plants languiſh and decay long before their time.

Thoſe gardeners who are fond of producing early Cucumbers, generally leave two or three of their early fruit, which are ſituated upon the main ſtem of the plant near the root, for ſeed; which, when fully ripe, they carefully ſave to a proper age for ſowing, and by this method they find a great improvement is made of the ſeed; and this they always uſe for their early crops only, for the ſucceeding crops do not deſerve ſo much care and attention.

I have here only mentioned the method of raiſing the young Cucumber plants in ſtoves; for as theſe conveniencies are now pretty generally made in the curious kitchen-gardens in moſt parts of England, this method may be more univerſally practiſed; but in ſuch gardens where there are no ſtoves, the ſeeds ſhould be ſown upon a well prepared hot-bed: and here it will be the beſt way to ſow the ſeeds in ſmall halfpenny pots, becauſe theſe may be eaſily removed from one bed to another, if the heat ſhould decline; or, on the contrary, if the heat ſhould be too great, the pots may be raiſed up, which will prevent the ſeed or the young plants from being injured thereby.

When the plants are come up as was before directed, there ſhould be a freſh hot-bed prepared, with a ſufficient number of halfpenny pots plunged therein ready to receive the plants, which muſt be planted into them in the ſame manner as was before directed, and the after-management of the plants muſt be nearly the ſame; but as the ſteam of the hot-bed frequently occaſions great damps, there muſt be great care to turn and wipe the glaſſes frequently, to prevent the condenſed moiſture falling on the plants, which is very deſtructive to them. There muſt alſo be great attention to the admitting freſh air at all proper times, as alſo to be careful in keeping the bed to a proper temperature of heat; for as there is a want of fire to warm the air, that muſt be ſupplied by the heat of dung, afterward theſe plants muſt be ridged out in the ſame manner as before directed.

If the bed is of a good temper for heat, your plants will take root in leſs than twenty-four hours; after which time you muſt be careful to let in a little air at ſuch times when the weather will permit, as alſo to turn the glaſſes upſide down every day to dry; for the ſteam of the bed condenſing on the glaſſes, will fall down upon the plants, and be very injurious to them; therefore whenever the weather is ſo bad as not to permit the glaſſes to lie turned long, you ſhould at leaſt turn them once or twice a day, and wipe off the moiſture with a woollen cloth; but you muſt alſo be very careful how you let in too much cold air, which is equally deſtructive to the tender plants; therefore, to avoid this, it is a very good method to faſten before the upper ſide of the frame, where the air is ſuffered to enter the bed, a piece of coarſe cloth or mat, ſo that the air which enters may paſs through that, which will render it leſs injurious to your plants.

You muſt alſo be very cautious in giving water to the plants while young; and whenever this is done, it ſhould be ſparingly, and the water ſhould be placed either into a heap of dung, or in ſome other warm place, for ſome time before it is uſed, ſo as to be nearly of a temperature for warmth with the incloſed air of the hot-bed; and as the plants advance in height, you ſhould have a little dry ſifted earth always ready to earth up their ſhanks, which will greatly ſtrengthen them. You muſt alſo be very careful to keep up the heat of the bed, which, if you ſhould find decline, you muſt lay a little freſh litter round about the ſides of the bed, and alſo keep the glaſſes well covered in the nights, or in bad weather: but if, on the other hand, your bed ſhould prove too hot, you ſhould thruſt a large ſtake into the ſide of the dung in two or three places, almoſt to the middle of the bed, which will make large holes, through which the greateſt part of the ſteam will paſs off without aſcending to the top of the bed; and when you find it has anſwered your purpoſe by ſlacking the heat of your bed, you muſt ſtop them up again with dung.

Theſe directions, if carefully attended to, will be ſufficient for raiſing the plants in the firſt bed: you muſt therefore, when you perceive the third, or rough leaf begin to appear, prepare another heap of freſh dung, which ſhould be mixed with aſhes, as was before directed; this ſhould be in quantity according to the number of holes you intend to make. The common allowance for ridging out the earlieſt plants is, one load to each light or hole, ſo that the bed will be near three feet thick in dung; but for ſuch as are not ridged out till March, two loads of dung will be ſufficient for three holes, for I could never obſerve any advantage in making theſe beds ſo thick with dung as ſome people do; their crops are ſeldom better, if ſo good, as thoſe which are of a moderate ſubſtance; nor are they forwarder, and the fruit is rarely ſo fair, nor do the Vines continue ſo long in health.

In making theſe beds, you muſt carefully mix the dung, ſhaking it well with the fork, ſo as not to leave any clods of dung unſeparated, as alſo to beat it down pretty cloſe, to prevent the ſteam from riſing too haſtily; you muſt alſo be careful to lay it very even, and to beat or preſs down the dung equally in every part of the bed, otherwiſe it will ſettle in holes, which will be very hurtful. When you finiſh laying the dung, you muſt make a hole exactly in the middle of each light, about a foot deep, and eight or nine inches over; theſe holes muſt be filled with light freſh earth, which ſhould be ſcreened to take out all large ſtones, clods, &c. laying it up in a hill; and in the middle of each thruſt in a ſtick about eighteen inches long, which ſhould ſtand as a mark to find the exact place where the hole is; then earth the bed all over about three inches thick, levelling it ſmooth, and afterwards ſet the frame upon it, covering it with glaſſes; but if there is any apprehenſion of the dung heating too violently, the earth ſhould not be laid upon the bed until the heat is ſomewhat abated, which will be in a few days, and then the earth may be laid upon the bed by degrees, covering it at firſt two inches thick; and a week or ten days after another inch in thickneſs may be laid on, but there ſhould be the whole thickneſs of earth laid upon the bed before the Vines begin to run; and if this thickneſs of earth is at laſt ſix or ſeven inches, the Vines will grow the ſtronger for its being ſo thick; for if the roots are obſerved, they will be found to ſpread and cover the whole bed as much as the Vines extend above; and when the earth is very ſhallow, or too light, the Vines will hang their leaves every day for want of a ſufficient depth of earth to ſupport their roots; ſo that if they are not conſtantly and well watered, they will not have ſtrength to laſt long, nor to produce fair fruit; and the giving them too much water is not ſo proper, nor will it anſwer near ſo well, as the giving a depth of earth upon the dung.

In four or five days time your bed will be in fit order to receive your plants, of which you may eaſily judge by pulling out one of the ſticks which was put in the
middle

middle of the holes, and feeling the lower part of it, which will ſatisfy you what condition your bed is in; then you muſt ſtir up the earth in the middle of the hole with your hand, breaking all clods, and removing all large ſtones, making the earth hollow in form of a baſon; into each of theſe holes you muſt plant two plants, in doing of which, obſerve to make the holes for the plants a little ſlanting towards the middle of the baſon, eſpecially if your plants are long ſhanked; this is intended to place the roots of the plants as far as poſſible from the dung, to which if they approach too near, the lower part of their roots is ſubject to be burned off; then ſettle the earth gently to each plant, and, if the earth is dry, it will be proper to give them a little water (which ſhould be warmed to the temper of the bed, as was before directed;) and if the ſun ſhould appear in the middle of the day, they ſhould be ſhaded therefrom with mats until the plants have taken root, which will be in two or three days; after which, you muſt let them enjoy as much of the ſun as poſſible, obſerving to turn the lights in the day time to dry, as alſo to give a little air whenever the weather will permit.

You muſt alſo obſerve to keep the glaſſes covered every night, and in bad weather, but be very careful not to keep them covered too cloſe, eſpecially while the bed has a great ſteam in it, which will cauſe a damp to ſettle upon the plants, which, for want of air to keep the fluid in motion, will ſtagnate and rot them.

When your plants are grown to be four or five inches high, you muſt, with ſome ſlender-forked ſticks, incline them toward the earth, each one a ſeparate way; but this muſt be done gently at firſt, leſt by forcing them too much, you ſhould ſtrain or break the tender veſſels of the plants, which would be very hurtful to them. In this manner you ſhould, from time to time, obſerve to peg down the runners as they are produced, laying each in exact order, ſo as not to interfere or croſs each other; nor ſhould you ever after remove them from their places, or handle them too roughly, whereby the leaves may be broken or diſplaced, which is alſo equally injurious to them; but whenever you have occaſion to weed the bed between the plants, do it with great care, holding the leaves aſide with one hand, while with the other you pull out the weeds.

In about a month after they are ridged out, you may expect to ſee the beginnings of fruit, which very often are preceded by male flowers, which many people are ſo ignorant as to pull off, calling them falſe bloſſoms; but this I am fully convinced, by many experiments, is wrong; for theſe flowers are of abſolute ſervice to promote the welfare of the fruit, which, when theſe male flowers are entirely taken off, does very often fall away, and come to nothing: nor ſhould the Vines be pruned, as is too often the practice of unſkilful people, eſpecially when they are too luxuriant, which often happens when the ſeeds were freſh, or of the laſt year's ſaving, and the plants in good heart. If this ſhould happen to be the caſe, it would be very proper to pull up one of the plants, before they have run ſo far as to entangle with the other; for it often happens, that one or two plants are better than four or five, when they are vigorous; for when the frame is too much crouded with Vine, the fruit is ſeldom good, nor in ſuch plenty, as when there is a more moderate quantity of ſhoots; for the air being hereby excluded from the fruit, they often decay, and fall off very young.

You muſt alſo be very careful to cover the glaſſes every night when your fruit begins to appear, as alſo to lay a little freſh litter, or mowing of graſs round the ſides of the bed, to add a freſh heat thereto; for if the heat of the bed be ſpent, and the nights prove cold, the fruit will fall away and come to nothing; and when the ſun is extreme hot in the middle of the day, you muſt cover the glaſſes with mats to ſhade the Vines; for although they delight in heat, yet the direct rays of the ſun, when it has great force, are very injurious, by either ſcorching thoſe leaves which are near the glaſſes, or by cauſing too great a perſpiration, whereby the extreme part of the ſhoots and the large leaves are left deſtitute of nouriſhment, and the fruit will be at a ſtand, and often turn yellow before it arrives at half its growth; this is too often the caſe, when the beds have not a ſufficient depth of earth over the dung.

At this time, when your Vines are ſpread ſo as to cover the hot-bed, it will be of great ſervice when you water them, to ſprinkle them all over gently ſo as not to hurt the leaves; but obſerve to do this not at a time when the ſun is very hot, for hereby I have known a whole bed of Cucumbers ſpoiled; for the water remaining upon the ſurface of the leaves in drops, doth collect the rays of the ſun as it were to a focus, and ſo ſcorches the leaves, that in one day's time they have, from a bright green, become of the colour of brown paper. The watering of the beds all over will be of great ſervice, by giving nouriſhment to thoſe roots, which by this time will have extended themſelves all over the bed; and if the warmth of the bed ſhould now decline, it will be of great ſervice to add a lining of freſh dung round the ſides of the beds, to give a new heat to them; for as the nights are often cold at this ſeaſon, where the beds have not a kindly warmth left in them, the fruit will frequently drop off the Vines, when grown to the ſize of a little finger; and if upon this lining of dung there is a thickneſs of ſtrong earth laid for the roots of the plants to run into, it will greatly ſtrengthen them, and continue the plants in vigour a much longer time than they otherwiſe will do; for the roots of theſe plants extend to a great diſtance when they have room, which they cannot have in a bed not more than five feet wide; ſo that when they have no greater extent for their roots, the plants will not continue in vigour above five or ſix weeks, which, if they have a depth and extent of earth, will continue three months in bearing; ſo that where there are ſeveral beds made near each other, it will be the beſt way to fill up the bottom of the alleys between them with warm dung, and cover that with a proper thickneſs of earth, ſo as to raiſe them to the level of the beds.

Theſe directions, with diligent obſervation, will be ſufficient for the management of this crop of Cucumbers; and Vines thus treated will continue to ſupply you with fruit till the beginning of July, by which time the ſecond crop will come to bear; the ſowing and managing of which is what I ſhall next proceed to.

About the middle of March, or a little later, according to the earlineſs of the ſeaſon, you muſt put in your ſeeds, either under a bell-glaſs, or in the upper ſide of your early hot-bed; and when the plants are come up, they ſhould be pricked upon another moderate hot-bed, which ſhould be covered with bell or hand-glaſſes, placed as cloſe as poſſible to each other; the plants ſhould alſo be pricked at about two inches diſtance from each other, obſerving to water and ſhade them until they have taken new root, which will be in a very ſhort time. This is to be underſtood of ſuch places where a great quantity of plants are required, which is conſtantly the caſe in the kitchen-gardens near London; but where it is only for the ſupply of a family, there may be plants enough raiſed on the upper ſide of the beds where the firſt crop is growing; or if the Vines ſhould have extended themſelves ſo far as to cover the whole bed, whereby there will not be room to prick the plants, a ſingle light will contain a ſufficient number of plants, while young, to plant out in ridges, as will ſupply the largeſt family with Cucumbers during the latter ſeaſon. You muſt alſo cover the glaſſes with mats every night, or in very bad weather; but in the day time, when the weather is hot, you muſt raiſe the glaſſes with a ſtone on the oppoſite ſide from the wind, to give air to the plants, which will greatly ſtrengthen them; you muſt alſo water them as you ſhall find they require it, but this muſt be done ſparingly while the plants are young.

The middle of April the plants will be ſtrong enough to ridge out, you muſt therefore be provided with a heap of new dung, in proportion to the quantity of holes you intend to plant, allowing one load to ſix holes. When your dung is fit for uſe, you muſt dig a trench about two feet four inches wide, and in length juſt as you pleaſe, or the place will allow; and if the ſoil be dry, it ſhould be ten inches deep, but if wet, very little in the ground, levelling the earth in the bottom; then put in your dung, obſerving to ſtir and mix every part of it as was directed for the firſt hot-beds, laying it cloſe and even.

When this is done, you muſt make holes about eight inches over, and ſix inches deep, juſt in the middle of the ridge, and three feet and a half diſtance from each other; and if there be more than one ridge, the diſtance of thoſe ought to be eight feet and a half from each other; then fill the holes with good light earth, putting a ſtick into the middle of each for a mark, and afterwards cover the ridge over with earth about four inches thick, laying the earth the ſame thickneſs round the ſides. When the earth is levelled ſmooth, you muſt ſet the glaſſes on upon the holes, leaving them cloſe down about twenty-four hours, in which time the earth in the holes will be warmed ſufficiently to receive the plants; then with your hand ſtir up the earth in the holes, making it hollowin form of a baſon; into each of which you ſhould plant three or four plants, obſerving to water and ſhade them until they have taken root; after which time you muſt be careful to give them a little air by raiſing the glaſſes on the oppoſite ſide to the wind, in proportion to the heat of the weather, as alſo to water them as you ſhall ſee they require it; but you muſt only raiſe the glaſſes in the middle of the day, until the plants fill the glaſſes, at which time you ſhould raiſe the glaſſes with a forked ſtick on the ſouth ſide, in height proportionable to the growth of the plants, that they may not be ſcorched by the ſun; this alſo will harden and prepare the plants to endure the open air, but you ſhould not expoſe them too ſoon thereto; for it often happens, that there are morning froſts in May, which are many times deſtructive to theſe plants when expoſed thereto; it is therefore the ſureſt method to preſerve them under the glaſſes, as long as they can be kept in without prejudice to the plants; and if the glaſſes are raiſed with two bricks on the backſide, and the forked ſtick on the other ſide, they may be kept in a great while without danger.

Towards the latter end of May, when the weather appears ſettled and warm, you ſhould turn your plants down gently out of the glaſſes; but do not perform this in a very dry, hot, ſunny day, but rather when there is a cloudy ſky, and an appearance of rain; you muſt in doing of this raiſe the glaſſes either upon bricks, or forked ſticks, whereby they may ſtand ſecure at about four or five inches high from the ground, that the plants may lie under them without bruiſing; nor ſhould you take the glaſſes quite away till the latter end of June, or the beginning of July, for theſe will preſerve the moiſture much longer to their roots than if they were quite expoſed to the open air; about three weeks after you have turned the plants out of the glaſſes, they will have made a conſiderable progreſs, eſpecially if the weather has been favourable, at which time you ſhould dig up the ſpaces of ground between the ridges, laying it very even; then lay out the runners of the Vines in exact order, and be careful in this work not to diſturb the Vines too much, nor to bruiſe or break the leaves; this digging of the ground will looſen it, and thereby render it eaſy for the roots of the plants to ſtrike into it, as alſo render the ſurface of the earth more agreeable to the Vines that run upon it. After this there will be no farther care needful, but only to keep them clear from weeds, and to water them as often as they ſhall require, which they will ſoon ſhew, by the hanging of their greater leaves. The ridges, thus managed, will continue to produce large quantities of fruit from June until the latter end of Auguſt, after which time the coldneſs of the ſeaſon renders them unwholeſome, eſpecially if the autumn prove wet.

From theſe ridges people commonly preſerve their Cucumbers for ſeed, by making choice of two or three of the faireſt fruit upon each hole, never leaving above one upon a plant, and that ſituated near the root of it; for if you leave more, they will weaken the plant ſo much, that your other fruit will be ſmall, and fewer in number: but thoſe perſons who value themſelves upon producing Cucumbers very early, commonly leave three or four Cucumbers of the firſt produce of their earlieſt crop, when the fruit is fair; and the ſeeds of theſe early fruit, are generally preferred to any other for the firſt crop. Theſe ſhould remain upon the Vines until the middle or end of Auguſt, that the ſeeds may be perfectly ripe; and when you gather them from the Vines, it will be proper to ſet the fruit in a row upright againſt a hedge or wall, where they may remain until the outer cover begins to decay; at which time you ſhould cut them open, and ſcrape out the ſeeds, together with the pulp, into a tub, which ſhould be afterwards covered with a board, to prevent filth from getting amongſt the pulp. In this tub it ſhould be ſuffered to remain eight or ten days, obſerving to ſtir it well with a long ſtick to the bottom every day, in order to rot the pulp, that it may be eaſily ſeparated from the ſeeds; then pour ſome water into the tub, ſtirring it well about, which will raiſe the ſcum to the top, but the ſeeds will ſettle to the bottom; ſo that by two or three times pouring in water, and afterwards ſtraining it off from the ſeeds, they will be perfectly cleared from the pulp; then you ſhould ſpread the ſeeds upon a mat, which ſhould be expoſed to the open air three or four days until they are perfectly dry, when they may be put up in bags, and hung up in a dry place where vermin cannot come to them, where they will keep good for ſeveral years, but are generally preferred when three or four years old, as being apt to produce leſs vigorous, but more fruitful plants.

I ſhall, in the next place, proceed to give directions for managing Cucumbers for the laſt crop, or what are generally called picklers.

The ſeaſon for ſowing theſe is towards the latter end of May, when the weather is ſettled. The ground where theſe are commonly ſown, is between Cauliflowers, in the wide rows, between which are allowed four feet and a half ſpace when the Cauliflowers were planted. In theſe rows you ſhould dig up ſquare holes at about three feet and a half diſtance from each other, breaking the earth well with a ſpade, and afterwards ſmoothing and hollowing it in the form of a baſon with your hand; then put eight or nine ſeeds into the middle of each hole, covering them over with earth about half an inch thick; and if it ſhould be very dry weather, it will be proper to water the holes gently in a day or two after the ſeeds are ſown, in order to facilitate their vegetation.

In five or ſix days, if the weather be good, your plants will begin to thruſt their heads above ground; at which time you ſhould be very careful to keep off the ſparrows, which are very fond of the young tender ſeed-leaves of theſe plants; and, if they are not prevented, will deſtroy your whole crop: but as it is not above a week that the plants are in danger, it will be no great trouble to look after them during that time; for when the plants are come up, and have expanded their ſeed leaves, the ſparrows will not meddle with them.

You muſt alſo be careful to water them gently, as you find the drought of the ſeaſon may require; and when you perceive the third or rough leaf of the plants begin to appear, you muſt pull out all the weakeſt plants, leaving only three or four of the moſt promiſing and beſt ſituated in each hole, ſtirring the earth round about them with a ſmall hoe to deſtroy the weeds, and raiſe the earth about the ſhanks of the plants, putting a little earth between them, preſſing it gently down with your hand, that the plants may be thereby ſeparated from each other to a greater diſtance; then give them a little water (if the weather be dry) to ſettle the earth about them, which you muſt afterwards repeat as often as you ſhall find it neceſſary, ſtill being careful to keep the ground clear from weeds.

When your Cauliflowers are quite drawn off the ground from between the Cucumbers, you muſt hoe and clean the ground, drawing the earth up round each hole in form of a baſon, the better to contain the water when it is given them; you muſt alſo lay out the plants in exact order as they are to run and extend, ſo that they may not interfere with each other; then lay a little earth between the plants left, preſſing it down gently with your hand, the better to ſpread them each way, giving them a little water to ſettle the earth about them, repeating it as often as the ſeaſon ſhall require, and obſerving to keep the ground clean from weeds. The plants thus managed, will begin to produce fruit toward the latter end of July, when you may either gather them young for pickling, or ſuffer them to grow for large fruit.

The quantity of holes neceſſary for a family, is about fifty or ſixty; for if you have fewer, they will not produce enough at one gathering to make it worth the trouble and expence of pickling, without keeping them too long in the houſe, for you cannot expect to gather more than two hundred at each time from fifty holes; but this may be done twice a week during the whole ſeaſon, which commonly laſts five weeks; ſo that from fifty holes you may reaſonably expect to gather about two thouſand in the ſeaſon, which, if they are taken ſmall, will not be too many for a private family. And if ſo many are not wanted, they may be left to grow to a proper ſize for eating.

CUCUMIS AGRESTIS. See Momordica.

CUCURBITA. Lin. Gen. Plant. 968. Tourn Inſt. R. H. 107. [ſo called from Curvata, *Lat.* bended, becau ſethe fruit of this plant generally bends,] the Gourd.

The Characters are,

It hath male and female flowers in the ſame plant. The flowers have a bell-ſhaped empalement of one leaf, whoſe borders are terminated by five briſtles; the flowers are bell-ſhaped, adhering to the empalement, and are of one petal, which is veined and rough, divided at the top into five parts. The male flowers have three ſtamina, which are connected at their extremity, but are diſtinct at their baſe, where they adhere to the empalement; theſe are terminated by linear ſummits running up and down. The female flowers have a large germen, ſituated under the flower, ſupporting a conical trifid ſtyle, crowned by a large trifid ſtigma. The germen afterward becomes a large fleſhy fruit, having three ſoft membranaceous cells which are diſtinct, incloſing two rows of ſeeds which are bordered.

This genus of plants is ranged in the tenth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Syngeneſia, the plants having male and female flowers on the ſame plant, and the ſtamina of the male flowers being connected.

The Species are,

1. Cucurbita (*Lagenaria*) foliis cordatis denticulatis tomentoſis baſi ſubtus biglanduloſis; pomis lignoſis. Lin. Sp. 1434. *Gourd with heart-ſhaped, indented, woolly leaves, having two glands at their baſe, and a ligneous ſhell to the fruit.* Cucurbita longa, folio molli, flore albo. J. B. 2. 221. *Commonly called the Long Gourd.*
2. Cucurbita (*Pepo*) foliis lobatis, pomis lævibus. Lin. Sp. Plant. 1010. *Gourd with lobed leaves and a ſmooth fruit.* Cucurbita major rotunda, flore luteo, folio aſpero. C. B. P. 213. *Commonly called Pompion, or Pumpkin.*
3. Cucurbita (*Verrucoſa*) foliis lobatis, pomis nodoſo-verrucoſis. Lin. Sp. Plant. 1010. *Gourd with lobed leaves, and a warted knobby fruit.* Cucurbita verrucoſa. J. B. 2. 222. *Warted Gourd.*
4. Cucurbita (*Melopepo*) foliis lobatis, caule erecto, pomis depreſſo-nodoſis. Lin. Sp. Plant. 1010. *Gourd with lobed leaves, an erect ſtalk, and a depreſſed knotty fruit.* Melopepo clypeiformis. C. B. P. 312. *Commonly called Squaſh.*
5. Cucurbita (*Lignoſus*) foliis lobatis aſperis, flore luteo, pomis lignoſis. *Gourd with rough-lobed leaves, a yellow flower, aud fruit having a hard ſhell; commonly called Calabaſh.*

The firſt ſort is ſometimes propagated in the Engliſh gardens by way of curioſity, but the fruit is very rarely eaten here; though, if they are gathered when they are young, while their ſkins are tender, and boiled, they have an agreeable flavour. In the eaſtern countries theſe fruit are very commonly cultivated and ſold in the markets for the table, and are a great part of the food of the common people, from June to October. Theſe fruit are alſo eaten in both the Indies, where the plants are cultivated as culinary; and in thoſe countries, where the heat of their ſummers is too great for many of our common vegetables, theſe may be a very good ſubſtitute.

This ſort doth not vary like moſt of the others, but always produces the ſame ſhaped fruit; the plants of this extend to a great length, if the ſeaſon proves warm and favourable, and will then produce ripe fruit; but in cold ſummers, the fruit ſeldom grows to half its uſual ſize. I have meaſured ſome of theſe fruit when growing, which were ſix feet long, and a foot and a half round; the plants were near twenty feet in length: the ſtalks of this, and alſo the leaves, are covered with a fine ſoft hairy down; the flowers are large, white, and ſtand upon long foot-ſtalks, being reflexed at their brim; the fruit is generally incurved and crooked, and when ripe, is of a pale yellow colour. The rind of this fruit becomes hard, ſo that if the ſeeds and pulp are taken out, and the ſhell dried, it will contain water; and in thoſe countries where they are much cultivated, are uſed for many purpoſes.

The ſecond ſort, which is commonly known by the title of Pumpkin, is frequently cultivated by the country people in England, who plant them upon their dunghills, where the plants run over them, and ſpread to a great diſtance; when the ſeaſons are favourable, they will produce plenty of large fruit: theſe they uſually ſuffer to grow to maturity, then they cut open a hole on one ſide, and take the ſeeds out of the pulp as clean as poſſible, after which they fill the ſhell with Apples ſliced, which they mix with the pulp of the fruit, and ſome add a little ſugar and ſpice to it; then bake it in an oven, and eat it in the ſame manner as baked Apples; but this is a ſtrong food, and only fit for thoſe who labour hard, and can eaſily digeſt it.

Theſe may be propagated by ſowing their ſeeds in April, on a hot-bed; and when the plants come up, they ſhould be tranſplanted on another moderate bed, where they ſhould be brought up hardily, and have a great deal of air to ſtrengthen them; and when they have got four or five leaves, they ſhould be tranſplanted into holes made upon an old dunghill, or ſome ſuch place, allowing them a great deal of room to run, for ſome of the ſorts will ſpread to a great diſtance. I have meaſured a ſingle plant, which had run upwards of forty feet from the hole, and had produced a great number of ſide branches; ſo that if the plant had been encouraged, and all the ſide branches permitted to remain, I dare ſay it would have fairly overſpread twenty rods of ground; which, to ſome people, may ſeem like a romance, yet I can affirm it to be fact. But what is this to the account printed in the Tranſactions of the Royal Society, which was communicated to them by Paul Dudley, Eſq; from New England, wherein mention is made of a ſingle plant of this kind, which, without any culture, ſpread over a large ſpot of ground, and from which plant were gathered two hundred and ſixty fruits each, one with another, as big as a half peck.

There are ſeveral varieties of this fruit, which differ in their form and ſize; but as theſe are annually varying from ſeeds, ſo I have omitted the mentioning them, for they ſeldom continue to produce the ſame kinds of fruit three years together.

The third ſort is very common in moſt parts of America, where it is cultivated as a culinary fruit; of this ſort there are alſo ſeveral varieties, which differ in their form and ſize; ſome of theſe are flat, others round; ſome are ſhaped like a bottle, and others are oblong, their outer cover or rind being white when ripe, and covered with large protuberances or warts. The fruit are commonly gathered when they are half grown, and boiled by the inhabitants of America to eat as a ſauce with their meat; but in England they are only cultivated by way of curioſity, few perſons having a reliſh for them here, where they have a great variety of better eſculent plants at that ſeaſon, when theſe are fit for uſe. Theſe may be propagated in the ſame manner as the ſecond ſort.

The fourth ſort is alſo very common in North America, where it is cultivated for the ſame purpoſes as the third. This very often grows with a ſtrong, buſhy, erect ſtalk, without putting out runners from the ſide, as the other ſorts, but frequently varies; for after it has been cultivated a few years in the ſame garden, the plants will become trailing like the others, and extend their branches to as great diſtance; and yet I have known when part of the ſeeds, taken out from the ſame fruit have been ſown in another garden, at a conſiderable diſtance, the fruit have been the ſame, and the plants have grown erect, when thoſe which were ſown in the ſame garden, have produced trailing plants with larger fruit of a different ſhape.

The fruit of the fifth ſort hath a hard ſhell when ripe like the firſt, which may be dried and preſerved many years: theſe are of very different forms and ſize; ſome are ſhaped like a Pear, and are no bigger than a large Catherine Pear; ſome are as large as quart bottles, and almoſt of the ſame form; others are round and ſhaped like an Orange, and are of the ſame ſize and colour, but theſe are very variable; for I have cultivated moſt of the ſorts near forty years, and have not been able, with all poſſible care, to preſerve the varieties longer than two or three years in the ſame garden, without procuring freſh ſeeds from ſome diſtant place. Whether theſe changes are brought about by the admixture of the farina with each other, or from what cauſe I cannot ſay, becauſe I have frequently planted them at as great diſtance from each other as I poſſibly could in the ſame garden, and yet the effect has been the ſame as when near.

The firſt ſort requires to be treated more tenderly than the others, in order to procure ripe fruit; ſo the ſeeds ſhould be ſown upon a moderate hot-bed in April, and the plants afterward planted each into a penny pot, and plunged into a very moderate hot-bed to bring them forward; but they muſt not be tenderly treated, for if they have not a large ſhare of free air admitted to them every day, they will draw up weak. When the plants are grown too large to be continued in the pots, there ſhould be holes dug where they are deſigned to grow, and three or four barrows full of hot dung put into each; theſe ſhould be covered with earth, into which the plants muſt be planted, and covered with hand-glaſſes till they run out.

There are ſome people who plant theſe plants by the ſides of arbours, over which they train the vines; ſo that in a ſhort time they will cover the whole arbour, and afford a ſtrong ſhade, and upon ſome of theſe arbours I have ſeen the longeſt fruit. There are others who plant them near walls, pales, or hedges, to which they faſten the Vines, and train them to a great height: the Orange-ſhaped Gourd is the ſort which is moſt commonly ſo planted for the ornament of its fruit, which has a pretty effect, eſpecially when ſeen at ſome diſtance. All the ſorts require a large ſupply of water in dry weather.

Theſe plants requiring ſo much room to ſpread, and their fruit being very little valued in England, hath occaſioned their not being cultivated amongſt us; we having ſo many plants, roots, or fruits, which are greatly preferable to thoſe for kitchen uſes: but in ſome parts of America, where proviſions are not in ſo great plenty, or ſo great variety, theſe fruits may be very acceptable.

CUIETE See Crescentia.

CULMIFEROUS PLANTS [ſo called of Culmus, *Lat.* ſtraw or haulm,] are ſuch as have a ſmooth jointed ſtalk, uſually hollow, and at each joint wrapped about with ſingle, narrow, ſharp-pointed leaves; and their ſeeds are contained in chaffy huſks, as Wheat, Barley, &c.

CUMINOIDES. See Lagoecia.

CUMINUM. Lin. Gen. Plant. 313. Mor. Umb. Κύμινον, *Gr.* Cumin.

The Characters are,

It hath an umbelliferous flower; the general umbel is compoſed of ſmaller, which are divided into four parts; their involucrum is longer than the umbel. The great umbel is uniform; the flowers have five unequal petals, whoſe borders are inflexed, and five ſingle ſtamina, terminated by ſlender ſummits. It hath a large germen ſituated under the flower, ſupporting two ſmall ſtyles, crowned by ſingle ſtigmas. The germen afterward becomes an oval ſtriated fruit, compoſed of two oval ſeeds, which are convex and furrowed on one ſide, and plain on the other.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, the flower having five ſtamina and two ſtyles.

We have but one Species of this genus, viz.

Cuminum (*Cyminum.*) Lin. Mat. Med. 139. Cumin. Cuminum ſemine longiore. C. B. P. 146. *Cumin with a longer ſeed.*

This plant is annual, periſhing ſoon after the ſeeds are ripe; it ſeldom riſes more than nine or ten inches high, in the warm countries where it is cultivated; but I have never ſeen it grow more than three or four inches high in England, where I have ſometimes had the plants come ſo far as to flower very well, but never to produce ſeeds. The leaves of this plant are divided into long narrow ſegments like thoſe of Fennel, but much ſmaller; they are of a deep green, and generally turn backward at their extremity; the flowers grow in ſmall umbels at the top of the ſtalks; theſe are compoſed of five unequal petals, which are of a pale bluſh colour, and are ſucceeded by long, channelled, aromatic ſeeds.

The ſeeds of this plant is the only part uſed in medicine; theſe are ranged among the greater hot ſeeds; they conſiſt of very warm diſſolving parts, and are eſteemed good to expel wind out of the ſtomach and bowels, ſo they are frequently put into clyſters for that purpoſe, and are ſometimes given in powder; and outwardly applied, they are of great ſervice to eaſe the pains of the breaſt or ſide.

This plant is propagated for ſale in the iſland of Malta, where it is called Cumino aigro, i. e. *hot Cumin.* But Aniſe, which they alſo propagate in no leſs quantity, they call Cumino dulce, i. e. *ſweet Cumin.* So that many of the old botaniſts were miſtaken, when they made two ſpecies of Cumin, viz. acre and dulce.

If the ſeeds of this plant are ſown in ſmall pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed to bring up the plants, and theſe after having been gradually inured to the open air, turned out of the pots, and planted in a warm border of good earth, preſerving the balls of earth to their roots, and afterward kept clean from weeds, the plants will flower pretty well, and by thus bringing of the plants forward in the ſpring, they may perfect their ſeeds in very warm ſeaſons.

CUNILA. See Sideritis.

CUNONIA. Buttn. Cun. tab. 1. Antholyza. Lin. Gen. Plant. 56.

The Characters are,

The flowers grow alternate in an imbricated ſpike, each having a ſpatha or ſheath, compoſed of two ſpear-ſhaped concave leaves; the flower hath one ringent petal, having a ſhort ſlender tube, which is dilated at the chaps, and compreſſed on the ſides; the upper lip is arched, and ſtretched

ſtretched out a conſiderable length beyond the alæ or wings, and is rounded at the top: it hath three long ſlender ſtamina, which are ſituated in the upper lip, terminated by oblong flat ſummits, which are faſtened in their middle and lie proſtrate. It hath a ſlender ſtyle, which is ſhorter than the ſtamina, crowned by three cylindrical ſtigmas which join the ſummits, and are included in the upper lip. The germen, which is ſituated below the flower, becomes an oblong capſule with three cells, filled with compreſſed ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, the flowers having three ſtamina and one ſtyle, but he has joined it to the Antholyza, making it only a ſpecies of that genus; whereas by the form and characters of the flower, it ſhould be ſeparated from that, there being full as great difference between the flowers of this and thoſe of the Antholyza, as is between thoſe and the Gladiolus; for the flowers of Cunonia have no carina or under lip, but thoſe of the Antholyza have, in which one of the ſtamina is included, which is ſeparated from the other two, which are ſituated in the upper lip; but in this all three are of equal length, and ſituated in the hollow of the upper lip. The two wings of this are ſhort, whereas thoſe of Antholyza are long, ſo that I think they ſhould be ſeparated.

We have but one Species of this genus at preſent in the Engliſh gardens, which is

Cunonia (*Antholyza*) floribus ſeſſilibus, ſpathis maximis. Buttn. Cun. 211. tab. 1. *Cunonia with flowers ſitting cloſe to the ſtalk, and very large ſpathæ or ſheaths.* Dr. Linnæus titles it Antholyza ſtaminibus omnibus adſcendentibus. Sp. Plant. 37. *Antholyza with all the ſtamina aſcending.*

There is a plant of this kind figured in Cornutus's book of Canada plants, under the title of Gladiolus Æthiopicus, flore Coccineo, p. 78. but by his figure and deſcription, it appears to be a different ſpecies from this, his flowers having much ſmaller ſpathæ or ſheaths, nor does the ſtalks of his riſe near ſo high as this; there are alſo ſome other differences between them.

The ſeeds of this plant I received from the Cape of Good Hope, where it grows naturally, which ſucceeded ſo well in the Chelſea garden, as to produce a great number of plants, which flowered well the third ſeaſon after they appeared, and have continued to produce flowers, and perfect their ſeeds every year ſince.

This hath a compreſſed bulbous root, ſomewhat like that of Corn Flag, covered with a brown ſkin; from this ariſe ſeveral narrow ſword-ſhaped leaves, about nine inches long, and a quarter of an inch broad in the middle, terminating in acute points; theſe have one longitudinal midrib which is prominent, and two longitudinal veins running parallel on each ſide; they are of a ſea-green colour, and appear in autumn, growing in length all the winter; in ſpring the ſtalk ariſes from between the leaves, which is round, ſtrong, and jointed; at each joint is ſituated a ſingle leaf, which almoſt embraces the ſtalk for near three inches from the baſe, then by the curvature of the ſtalk it is ſeparated, ſtanding erect: the ſtalks riſe near a foot and a half high, which is generally curved two oppoſite ways; the upper part of the ſtalk is terminated by a looſe ſpike of flowers, coming out of large ſpathæ or ſheaths, compoſed of two oblong concave leaves, terminating in acute points: theſe are at their firſt appearance placed imbricatim over each other, but as the ſtalk increaſes in length, ſo theſe are ſeparated; from between theſe two leaves comes out the flower, each having a ſlender Saffron-coloured tube near half an inch long, which is then enlarged where the petal is divided, and the upper ſegment is extended two inches in length, being arched over the ſtamina and ſtyle. This is narrow as far as to the extent of the wings, but above them is enlarged and ſpread open half an inch in length, and is concave, covering the ſummits and ſtigmas which are extended to that length; the two wings are alſo narrow at their baſe, but are enlarged upward in the ſame manner, ending in concave obtuſe points, which are compreſſed together, and cover the ſtamina and ſtyle. This flower is of a beautiful ſoft ſcarlet colour, ſo makes a fine appearance, about the latter end of April or beginning of May, which is the ſeaſon of its flowering. After the flowers decay, the germen becomes an oval ſmooth capſule, opening in three cells, which are filled with flat bordered ſeeds.

This plant is too tender to thrive in the open air in England, ſo the roots muſt be planted in pots filled with light earth, and may remain in the open air till October, when they muſt be removed into ſhelter, either into an airy glaſs-caſe, or placed under a hot-bed frame, where the leaves will keep growing all winter, and in the ſpring the ſtalks ariſe and flower. During the winter ſeaſon, the plants will require a little water when the weather is mild, once a week, but it muſt not be given in great quantities, eſpecially in cold weather; in the ſpring they ſhould be watered oftener; and when the flowers are paſt, the pots ſhould be removed into the open air to perfect their ſeeds, which will ripen the latter end of June, ſoon after which the ſtalks will decay to the root, which will remain inactive till September. When the ſtalks are decayed, the roots may be taken out of the ground, and kept in a dry room till the end of Auguſt, when they ſhould be planted again.

This plant is eaſily propagated by offsets, which it ſends out in great plenty, or by ſowing of the ſeeds, which ſhould be ſown in pots about the middle of Auguſt, and placed in a ſituation where they may enjoy the morning ſun, and in dry weather ſhould be gently watered; in September the pots may be removed to a warmer ſituation, and in October they muſt be placed under a frame, where they may be protected from froſt and hard rains, but in mild weather enjoy the free air. The plants will appear in October, and continue growing all the winter, and in June their leaves will decay; then they may be taken up, and four or five roots may be planted in each pot, till they have grown another year, when they may be each put into a ſeparate pot. Theſe ſeedling plants muſt be ſheltered in the ſame manner as the old roots in winter, and the third year they will flower.

CUPRESSUS. Lin. Gen. Plant. 958. Tourn. Inſt. R. H. 587. tab. 358. Cypreſs [takes its name either of κύω, to bring forth, and πάρισος, becauſe it produces equal branches on both ſides; or of Cypariſſus, a certain infant whom the poets feign to have been transformed into a Cypreſs-tree.] The Cypreſs-tree.

The Characters are,

It hath male and female flowers growing at diſtances on the ſame plant; the male flowers are formed into oval katkins, in which the flowers are placed thinly, among ſeveral roundiſh ſcales, each having a ſingle flower. Theſe have no petals nor ſtamina, but have four ſummits which adhere to the bottom of the ſcales. The female flowers are formed in a roundiſh cone, each containing eight or ten flowers; the ſcales of the cones are oppoſite, each having a ſingle flower, theſe have no petals; the germen is ſcarce viſible, but under each ſcale there are many punctures or ſpots, and a concave truncated apex inſtead of a ſtyle; this afterward becomes a globular cone, opening in angular target-ſhaped ſcales, under which are ſituated angular ſeeds.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Monadelphia; the plants of this ſection have male and female flowers on the ſame plant, and the male flowers are joined in one bdoy.

The Species are,

1. Cupressus (*Sempervirens*) foliis imbricatis, ramis erectioribus. *Cypreſs with imbricated leaves, and upright branches.* Cupreſſus metâ in faſtigium convolutâ qua fæmina. Plinii. Dod. Pempt. 856. *Female or common upright Cypreſs.*

2. Cupressus (*Horizontalibus*) foliis imbricatis acutis, ramis horizontalibus. *Cypreſs with imbricated acute leaves, and branches growing horizontally.* Cupreſſus ramos extra ſe ſpargens quæ Mas. Plinii. Tourn. Inſt. R. H. 587. *Male ſpreading Cypreſs.*

3. Cupressus (*Luſitanica*) foliis imbricatis, apicibus aculeatis, ramis dependentibus. *Cypreſs with imbricated leaves terminating in ſpines, and branches hanging downward.* Cupreſſus Luſitanica, patula, fructu minore. Inſt. R. H. 587. *Portugal ſpreading Cypreſs with a ſmaller fruit.*

4. Cupressus (*Diſticha*) foliis diſtichis patentibus. Hort. Cliff. 409. *Cypreſs with leaves on two ſides the branches.* Cupreſſus Virginiana foliis Acaciæ deciduis. Hort. Amſt. 1. p. 113. *Virginia Cypreſs which ſheds its leaves, commonly called Deciduous Cypreſs.*

5. Cupressus (*Thyoides*) foliis imbricatis, frondibus ancipitibus. Lin. Sp. Plant. 1003. *Cypreſs with imbricated leaves, and branches ſtanding two ways.* Cupreſſus nana Mariana, fructu cæruleo parvo. Pluk. Mant. 61. *Dwarf Maryland Cypreſs with a ſmall blue fruit.*

6. Cupressus (*Africana*) foliis linearibus ſimplicibus cruciatim poſitis. *Cypreſs with narrow ſingle leaves placed croſſways.* Cupreſſus Africana of Herman and Oldenburgh. *African Cypreſs-tree, called by the Dutch Cypreſs Boom.*

The firſt of theſe trees is very common in moſt of the old gardens in England, but at preſent is not ſo much in requeſt as formerly, though it is not without its advantages; nor ſhould it be entirely rejected, although many perſons are of that opinion; for it ſerves to add to the beauty of wilderneſſes, or clumps of Evergreens, and where they are properly diſpoſed, they have their beauties. It was formerly planted in borders of pleaſure-gardens, and kept ſhorn into a pyramidal or conic form; and ſome people, believing them ſubject to be killed if they cut them, tied them up with cords into a pyramidal figure, which form they are naturally diſpoſed to grow in; but this winding them about, prevented the air from entering the inward parts of the branches, ſo that the leaves decayed, and became unſightly, and greatly retarded their growth. And thoſe which are ſheared, if the operation is not performed in the ſpring, or early in the ſummer, are very ſubject to be injured by ſharp winds and cuttings froſts in winter. Wherefore, upon the whole, I think it much better to ſuffer them to grow wild as they are naturally diſpoſed, planting them only amongſt other Evergreen Trees, where, by the darkneſs of their green leaves, together with their waving heads, they will greatly add to the variety.

The ſecond ſort is by far the largeſt growing tree, and is the moſt common timber in ſome parts of the Levant. This, if planted upon a warm, ſandy, gravelly ſoil, will proſper wonderfully; and though the plants of this ſort are not ſo finely ſhaped as thoſe of the firſt, yet they greatly recompenſe for that defect, by its vigorous growth and ſtrength, in reſiſting all weathers. This tree is very proper to intermix with Evergreens of a ſecond ſize next to Pines and Firs, to form clumps; in which claſs it will keep pace with the trees of the ſame line, and be very handſome. Beſides, the wood of this tree is very valuable, when grown to a ſize fit for planks, which I am convinced it will do in as ſhort a ſpace as Oaks; therefore, why ſhould not this be cultivated for that purpoſe, ſince there are many places in England where the ſoil is of a ſandy or gravelly nature, and ſeldom produces any thing worth cultivating? Now, in ſuch places theſe trees will thrive wonderfully, and greatly add to the pleaſure of the owner, while growing, and afterwards render as much profit to his ſucceſſors, as perhaps the beſt plantation of Oaks; eſpecially ſhould the timber prove as good here, as in the iſlands of the Archipelago, which I ſee no reaſon to doubt of; for we find it was ſo gainful a commodity to the iſland of Candia, that the plantations were called Dos Filiæ, the felling of one of them being reckoned a daughter's portion. The timber of this tree is ſaid to reſiſt the worm, moth, and all putrefaction, and is ſaid to laſt many hundred years. The doors of St. Peter's church at Rome were framed of this material, which laſted from the great Conſtantine to Pope Eugenius IVth's time, which was eleven hundred years, and were then ſound and entire, when the Pope would needs change them for gates of braſs. The coffins were made of this material, in which Thucydides tells us the Athenians uſed to bury their heroes; and the mummy cheſts, brought with thoſe condited bodies out of Egypt, are many of them of this material.

This tree is by many learned authors recommended for the improvement of the air, and a ſpecific for the lungs, as ſending forth great quantities of aromatic and balſamic ſcents; wherefore many of the antient phyſicians of the Eaſtern countries uſed to ſend their patients, who were troubled with weak lungs, to the iſland of Candia, which at that time abounded with theſe trees, where, from the effects of the air alone, very few failed of a perfect cure.

The fourth ſort is a native of America, where it grows in watery places, and riſes to a prodigious height, and is of a wonderful bulk. I have been informed, that there are trees of this kind in America which are upwards of ſeventy feet high, and ſeveral fathoms in circumference, which trees grow conſtantly in the water; therefore they may probably be of ſingular advantage to plant in ſuch ſwampy or wet ſoils, where few other trees will grow, eſpecially of the reſinous kind. That they are very hardy in reſpect to cold, is evident, from ſome few trees of this kind which were formerly planted in England; particularly one in the gardens of John Tradeſcant, at South Lambeth, near Vaux-Hall, which is upwards of thirty feet high, and of a conſiderable bulk, which, though in a common yard at preſent, where no care is taken of it, but, on the contrary, many hooks are driven into the trunk, to faſten cords thereto for drying of cloaths, yet the tree is in great health and vigour, but hath not produced any fruit as yet, which may be occaſioned for want of moiſture: for we often ſee many aquatic plants will grow upon a drier ſoil, but yet are ſeldom ſo productive of either flowers or fruit, as thoſe which remain growing in the water.

There is alſo a pretty large tree of this kind now growing in the gardens of the late Sir Abraham Janſſen, Bart. at Wimbleton in Surry, which has produced great quantities of cones for ſome years paſt, which, in favourable ſeaſons come to maturity, and the ſeeds have been as good as thoſe which have been brought from America. This tree was tranſplanted when it was very large, which has ſtinted its growth; which, together with its being planted upon a dry ſoil, may have occaſioned its fruitfulneſs, for it has made very little progreſs in its growth ſince it was removed.

Theſe trees are all propagated from ſeeds, which ſhould be ſown early in the ſpring on a bed of warm, dry, ſandy earth, which muſt be levelled very ſmooth; then ſow the ſeeds thereon pretty thick, ſifting the ſame light earth over them half an inch thick. If the weather ſhould prove very warm and dry, it will be proper to ſhade the bed from the ſun in the daytime, and water the bed, which muſt be done very carefully, obſerving not to waſh the ſeeds out of the ground. In about two months time (if your ſeeds are good) the young plants will appear above ground, which muſt be conſtantly kept clean from weeds, and in very dry weather ſhould be often refreſhed with water; but this ſhould be done with great caution, leſt you beat theſe tender rooted plants out of the ground. If the ſeeds are ſown upon a moderate hot-bed, and the bed covered with mats, they will come up much ſooner, and with greater certainty, than when they are ſown in the cold ground.

In this bed the young plants may remain two years, by which time they will have ſtrength enough to be tranſplanted into a nurſery; but while the plants are young, they are tender, ſo ſhould be covered in ſevere froſt with mats to prevent their being injured thereby. The beſt ſeaſon for removing them is in the beginning of April, when the drying eaſterly winds of March are over, and, if poſſible, chooſe a cloudy day, when it is inclinable to rain; and in taking them out of the ſeed-bed, preſerve the roots as entire as poſſible, and, if you can, a ball of earth to each plant. The ſoil in which theſe trees ſhould be planted (as I before ſaid) ſhould be, for the two firſt ſorts, a warm ſand or gravel, which, when you have prepared, by carefully digging and cleanſing from all noxious weeds, you muſt lay level. Then draw the lines where the trees are to be planted at three feet aſunder, and plant the trees at eighteen inches diſtance in the rows, obſerving to cloſe the earth well to their roots, as alſo to lay a little mulch upon the ſurface of the ground about their ſtems; and water them well to ſettle the earth to their roots, which ſhould be repeated twice a week, until the plants have taken freſh root.

Theſe plants may remain in the nurſery three or four years, according to the progreſs they make, or till your ground is ready where they are to be planted: but if you intend to let them remain longer, you ſhould take up every other tree in the rows, and tranſplant out; for otherwiſe their roots will be matted together, ſo that it will render it difficult to tranſplant them, as alſo endanger the future growth of the trees. The plants ſhould by no means be let ſtand too long in the nurſery before they are tranſplanted out for good, becauſe the roots do not mat together ſo cloſely as thoſe of many other ſorts of Evergreen Trees, whereby they may be taken up with good balls of earth to their roots; but the roots of the Cypreſs are apt to extend out in length, ſo it is one of the moſt difficult trees to remove when grown large; therefore moſt curious perſons chooſe to plant the young plants into ſmall pots, when they firſt take them out of the ſeed-bed, and ſo train them up in pots two or three years, until they are fit to plant out where they are to ſtand for good, and, by this management, they are ſecure of all the plants; for theſe may be ſhaken out of the pots at any time of the year without danger, and planted with their whole ball of earth, which is likewiſe a great advantage. When they are planted out for good (if they are deſigned for timber) they ſhould be planted about twelve or fourteen feet diſtance every way, and be very careful in removing thoſe in the full ground, not to ſhake the earth from their roots; to prevent which, you ſhould open the ground about each tree, cutting off all long roots, then working under the ball of earth, cut the downright roots off; and after having pared off all the earth from the upper part of the ball, as alſo reduced the bulk of it, ſo that its weight may not be too great for the fibres to ſupport, they may be carried upon a handbarrow by two perſons to the place where they are to be planted; but if they are to be carried to a diſtant place, they ſhould either be put into baſkets, or their roots cloſely matted up. When they are planted, you muſt ſettle the earth cloſe to their roots as before, laying a little mulch upon the ſurface of the ground about their ſtems, to prevent the ſun and wind from entering the earth to dry their fibres; and water them well, to ſettle the ground to their roots, which muſt alſo be repeated, if the weather proves dry, until they have taken root, after which time they will require little more care than to keep them clear from weeds.

The firſt, which is the moſt common ſort in England, ſeldom produces good ſeeds in this country; it is therefore the beſt way to have the cones brought over entire from the ſouth parts of France and Italy, where they ripen perfectly well, and take the ſeeds out juſt before you ſow them, for they will keep much better in the cones than if they are taken out. The method to get the ſeeds out is to expoſe the cones to a gentle heat, which will cauſe them to open, and eaſily emit their ſeeds.

The ſecond ſort grows naturally in the Levant, and from thence it has been formerly brought to Italy, but at preſent this is pretty rare in England; for what has paſſed under this title here, is only a variety of the common ſort, whoſe branches grow much looſer, and not ſo upright as the firſt; but the cones taken from theſe trees, and the ſeeds ſown, have frequently produced plants of both varieties; but the true ſpreading Cypreſs extends its branches horizontally from the firſt year, and continues to extend them to a great length as the plants advance, and the plants raiſed from the ſeeds do not vary, ſo that it is certainly a diſtinct ſpecies. This grows to be a large timber tree in the Levant, and in Italy there are ſome of a conſiderable ſize.

The Virginian kind may alſo be propagated in as great plenty, for the cones of this may be eaſily procured from Carolina or Virginia, in both which places they grow in great abundance; and the ſeeds will riſe as eaſily as any of the other ſorts, and the plants are equally as hardy: theſe have been formerly kept in pots, and houſed in winter, with which management they have not ſucceeded ſo well as they have done in England, ſince people have planted them into the full ground; and where they have had a moiſt ſoil, I have obſerved them to thrive beſt, which is ſince confirmed by Mr. Cateſby, in his Natural Hiſtory of Carolina; where he ſays, that this tree grows in places where the water commonly covers the ſurface of the ground three or four feet, ſo that it may be a very great improvement to our boggy ſoils. This tree, caſting its leaves in winter, does not ſo well ſuit with plantations of Evergreens at that ſeaſon; though, in ſummer, when there is the greateſt pleaſure in walking among plantations of trees, it hath ſo much the appearance of an Evergreen, as to paſs for ſuch. It may alſo be propagated by cuttings, which ſhould be planted in a bed of moiſt earth in the ſpring before they begin to ſhoot.

The third ſort is at preſent pretty rare in the Engliſh gardens, though of late years there have been many plants raiſed here; but this ſort is not quite ſo hardy, I fear, as the common Cypreſs, for the plants are frequently killed, or greatly injured in ſevere winters; and in the hard froſt in 1740, there was a large tree of this kind entirely killed in the gardens of his Grace the Duke of Richmond, at Goodwood in Suſſex, which had been growing there ſeveral years; and in the year 1762, many large trees were killed. There are great plenty of theſe trees growing at a place called Buſaco, near Cœmbra in Portugal, where this tree is called the Cedar of Buſaco; and there it grows to be a timber tree, ſo that from thence the ſeeds may be eaſily procured.

This tree grows naturally at Goa, from whence it was firſt brought to Portugal, where it has ſucceeded, and been propagated; formerly there were ſome trees of this ſort growing in the Biſhop of London's garden at Fulham, where it paſſed under the title of Cedar of Goa, by which it was ſent from thence to the Leyden garden with that name.

The fifth ſort is a native of North America, where it grows to a conſiderable height, and affords an uſeful timber to the inhabitants for many purpoſes. This ſort is extremely worth cultivating in England; for as it grows in a much colder country, there is no danger of its thriving well in the open air in England; and being an Evergreen of regular growth, will add to the variety of wilderneſs quarters, or other plantations of Evergreen Trees.

This ſort is propagated by ſeeds, which ſhould be ſown in the ſpring in boxes or tubs filled with light freſh earth, and placed where they may enjoy the morning ſun till eleven or twelve o'clock. In dry weather they ſhould be duly watered, and conſtantly kept clear from weeds. In this ſituation they may remain till Michaelmas, when they ſhould be removed to a warmer place; for the plants ſeldom appear till the following ſpring, ſo that it will be proper to place the boxes or tubs near a ſouth wall, pale, or hedge, during the winter ſeaſon; leſt, by being too much ſhaded, the wet of the winter ſeaſon ſhould rot the ſeeds. In the ſpring following, if theſe tubs or boxes are placed on a moderate hot-bed, it will bring up the plants very ſoon, and greatly forward their growth; but as the ſpring advances, they ſhould be inured to bear the open air by degrees; and in May they muſt be taken out of the hot-bed, and placed in a ſheltered ſituation, where they may enjoy the morning ſun, being careful to keep them clear from weeds, as alſo to water them duly in dry weather. The following winter it will be proper to remove the tubs near a ſouth wall or pale, for the plants being very young, are ſometimes tenderer than they will be afterward. Toward the latter end of March, or the beginning of April, juſt before the plants begin to ſhoot, they ſhould be carefully taken up out of the boxes; and having prepared a bed or two (according to the quantity of plants raiſed) of freſh earth in a ſheltered ſituation, the plants ſhould be planted therein in rows about eighteen inches aſunder, and about a foot diſtance plant from plant in the rows. This work ſhould be done in cloudy weather, when there is rain; for in dry weather, when eaſterly winds commonly blow at this ſeaſon, it will be very dangerous to tranſplant theſe plants; ſo that it had better be deferred a fortnight longer, till there is an alteration of the weather, than hazard the plants. When the plants are planted, they ſhould be watered to ſettle the earth to their roots; and then the ſurface of the ground ſhould be covered with mulch, to prevent the ſun and wind from penetrating to the roots of the plants; for nothing is more injurious to theſe plants, than to have their fibres dried when they are tranſplanted; therefore the plants ſhould not be taken out of the tubs till you are ready to place them in the ground, for they will not bear to lie out of the ground any time without great danger.

The branches of this tree are garniſhed with flat evergreen leaves, reſembling thoſe of the Arbor Vitæ; and the cones are no larger than the berries of the Juniper, from which they are not eaſily diſtinguiſhed at a little diſtance; but upon cloſely viewing, they are perfect cones, having many cells like thoſe of the common Cypreſs. If theſe trees are planted in a moiſt ſtrong ſoil, they make very great progreſs, and may, in ſuch ſituations, become profitable for timber; but however this tree may ſucceed for timber, yet it will be a great ornament to large plantations of evergreen trees, eſpecially in ſuch places where there is naturally a proper ſoil for them; becauſe, in ſuch ſituations, there are not many ſorts of Evergreen Trees which thrive well, eſpecially in cold places, and by increaſing the number of ſorts of theſe Evergreens, we add to the beauty of our gardens and plantations.

The third ſort ſends forth its branches almoſt horizontally, ſo that they extend to a great diſtance every way, and the trees are generally furniſhed with branches from the ground upward; but as theſe grow without much order, the trees have a very different appearance from all the other ſorts. This grows to be a large timber tree in Portugal, but the largeſt tree which I have ſeen in England, has not been above fifteen feet high, and the ſide branches of this were extended more than eight feet on every ſide from the ſtem. This ſort may be propagated from ſeeds in the ſame manner as the common Cypreſs, and the plants ſhould be treated in the ſame manner as hath been directed for them, with this difference only, that it will be proper to cover theſe plants during the two firſt winters after they are come up, eſpecially if the froſt ſhould be ſevere, which might deſtroy them, if they are expoſed to it while they are young. This ſort may alſo be propagated by cuttings, which, if planted in autumn, and ſcreened in winter, they will take root; but it is generally two years before they will be rooted enough to tranſplant, nor will the plants ſo raiſed thrive ſo faſt as the ſeedlings; therefore, when the ſeeds can be obtained, that is the beſt method to propagate this tree. The American deciduous Cypreſs may alſo be propagated by cuttings, as I have ſeveral times tried; ſo that when ſeeds cannot be had, this method may be practiſed ſucceſsfully. I ſuppoſe the common ſort will alſo take from cuttings; but this I have not experienced, ſo cannot recommend it to practice.

Theſe trees are ſo very ornamental to gardens, that no large garden can be compleat without many of them; and it is to theſe trees that the Italian villas owe a great ſhare of their beauty, for there is no tree ſo proper to place near buildings; the pyramidal upright growth of their branches affords a pictureſque appearance, and obſtructs not the view of the building, and the dark green of their leaves make a fine contraſt with the white of the building; ſo that, wherever there are temples or other buildings erected in gardens, there is no ſort of tree ſo proper to place near them as theſe. In all the landſchapes of Italian villas, we ſee many Cypreſs-trees repreſented; which have a very agreeable effect in the picture; and the trees, when rightly diſpoſed in a garden, afford a no leſs agreeable proſpect.

The ſeeds of the ſixth ſort were ſent me from the Cape of Good Hope, where the trees grow naturally, and by the account which I received with the ſeeds, the cones of the tree are black when ripe. The young plants which I have raiſed from theſe ſeeds have looſe ſpreading branches, which are cloſely garniſhed with narrow ſtrait leaves, which come out oppoſite, and are alternately croſſing each other; theſe are near one inch long, and of a light green colour; they continue in verdure all the year. Theſe plants being young, are too tender to thrive in the open air in England as yet; but when they have obtained more ſtrength, it is very probable they may do well in warm ſituations. I had two of theſe plants growing in the full ground, which were killed in the winter 1756. But thoſe which were placed under a frame, where there were no covering of glaſs, and only wooden ſhutters, were not injured by the cold, though the earth of the pots was frequently hard frozen.

CURCUMA. Lin. Gen. Plant. 6. Cannacorus. Tourn. Inſt. R. H. 367. Turmerick.

The CHARACTERS are,

The flowers have each ſeveral ſpathæ, which are ſingle and drop off; the flower hath one petal with a narrow tube, which is cut at the brim into three ſegments; it hath an oval-pointed nectarium of one leaf, which is inſerted in the ſinus of the largeſt ſegment of the petal; it hath five ſtamina, four of which are barren, and one fruitful, which is ſituated within the nectarium, and hath the appearance of a petal, having a bifid point, to which the ſummit adheres. It hath a roundiſh germen ſituated under the flower, ſupporting a ſtyle the length of the ſtamina, crowned by a ſingle ſtigma. The germen afterward becomes a roundiſh capſule, having three cells, which are filled with roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's firſt claſs, intitled Monandria Monogynia, the flower having one ſtamina and one ſtyle.

The SPECIES are,

1. CURCUMA (*Rotunda*) foliis lanceolato-ovatis, nervis lateralibus rariſſimis. Lin. Sp. Plant. 2. *Curcuma with ſpear-ſhaped oval leaves, having very few nerves on the ſides.* Curcuma radice rotundâ. C. B. *Turmerick with a round root.*
2. CURCUMA (*Longa*) foliis lanceolatis nervis lateralibus numeroſiſſimis. Lin. Sp. Plant. 2. *Curcuma with ſpear-ſhaped leaves, having many lateral veins.* Curcuma radice longâ. H. L. 288. *Turmerick with a long root.*

The firſt ſort hath a fleſhy jointed root ſomewhat like that of Ginger, but rounder, which ſends up ſeveral ſpear-ſhaped oval leaves, that riſe upwards of a foot high; theſe have one longitudinal midrib, and a few tranſverſe nerves running from the midrib to the ſides; they are of a ſea-green colour; from between theſe ariſe the flower-ſtalk, ſupporting a looſe ſpike of flowers of a pale yellowiſh colour, incloſed in ſeveral different ſpathæ or ſheaths, which drop off. Theſe flowers are never ſucceeded by ſeeds in the gardens here.

The ſecond ſort hath long fleſhy roots, of a deep yellow colour, which ſpread under the ſurface of the ground like thoſe of Ginger; they are about the thickneſs of a man's finger, having many round knotty circles, from which ariſe four or five large ſpear-ſhaped leaves, ſtanding upon long foot-ſtalks; they have a thick longitudinal midrib, from which a numerous quantity of veins are extended to the ſides; theſe leaves are of a glaucous or ſea-green colour. The flowers grow in looſe ſcaly ſpikes on the top of the foot-ſtalks, which ariſe from the larger knobs of the roots, and grow about a foot high; they are of a yellowiſh red colour, and ſhaped ſomewhat like thoſe of the Indian Reed.

Theſe plants grow naturally in India, from whence the roots are brought to Europe for uſe. They are very tender, ſo will not live in this country, unleſs they are placed in a warm ſtove. As they do not produce ſeeds in England, they are only propagated by parting their roots: the beſt time for removing and parting theſe roots is in the ſpring, before they put out new leaves; for the leaves of theſe plants decay in autumn, and the roots remain inactive till the ſpring, when they put out freſh leaves. The roots ſhould be planted in rich kitchen-garden earth, and the pots ſhould be conſtantly kept plunged in a bark-bed in the ſtove. In the ſummer ſeaſon, when the plants are in a growing ſtate, they will require to be frequently refreſhed with water, but it ſhould not be given to them in large quantities; they ſhould alſo have a large ſhare of air admitted to them in warm weather. When the leaves are decayed, they ſhould have very little wet, and muſt be kept in a warm temperature of air, otherwiſe they will periſh. Theſe plants uſually flower in Auguſt, but it is only the ſtrong roots which flower, ſo they muſt not be parted into ſmall roots, where the flowers are deſired.

CURRAN-TREE. See Ribes.

CURURU. See Paullinia.

CUSPIDATED PLANTS [ſo called, of cuſpis, *Lat.* the point of a ſpear] are ſuch plants, the leaves of which are pointed like a ſpear.

CUSTARD-APPLE. See Annona.

CYANELLA. Royen.

The Characters are,

The flower has no empalement; it hath ſix oblong, concave, ſpreading petals, which join at their baſe, the three lower hanging downward, with ſix ſhort ſpreading ſtamina, terminated by oblong erect ſummits, and a three-cornered obtuſe germen, ſupporting a ſlender ſtyle the length of the ſtamina, having an acute ſtigma. The germen afterward becomes a roundiſh capſule, having three furrows, with three cells, incloſing many oblong ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, the flower having ſix ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Cyanella (*Capenſis*). Lin. Sp. 443. Cape Cyanella.

This plant grows naturally at the Cape of Good Hope. The root is ſhaped like thoſe of the Spring Crocus; the leaves are long, narrow, and have a ſulcus on their upper ſide; the foot-ſtalk of the flower ariſes immediately from the root, ſupporting one flower with ſix petals, of a fine blue colour, which appears in May, but the flowers have not been ſucceeded by ſeeds as yet in England.

It is too tender to thrive in the full ground in this country, therefore the roots ſhould be planted in pots filled with light earth; and in winter muſt be placed in a frame, and treated in the ſame manner as is directed for Ixia, with which the plant will thrive and produce flowers annually.

CYANUS. See Centauria.

CYCAS, the Sago-tree.

There are ſeveral ſmall plants of this ſort in the Engliſh gardens, but from theſe no characters of the tree can be drawn; nor are there any juſt accounts of theſe to be met with in the ſeveral authors who have figured and deſcribed the tree.

We know but one Species of it at preſent, viz.

Cycas (*Circinalis*) frondibus pinnatis circinalibus, foliolis linearibus planis. Lin. Sp. 1658. *Sago-tree with full branches, whoſe wings are placed circularly, and the ſmall leaves are plain.* Arbor Zagoe Amboinenſis. Seb. Theſ. 1. p. 39.

This tree has been ranged in the tribe of Palms, to which it has great affinity, eſpecially by its outer appearance the branches and trunk having the ſame ſtructure.

This tree requires to be plunged into tanners bark in a ſtove, which ſhould be kept up full to temperate heat in winter; but in ſummer ſhould be much warmer, when it ſhould be frequently refreſhed with water during hot weather, but in autumn and winter it ſhould be given ſparingly.

Moſt of the plants of this kind now in the Engliſh gardens, have been communicated to the poſſeſſors by Richard Warner, Eſq; of Woodford, in Eſſex, who received a tree of this ſort, which was brought from India by the late Captain Hutchenſon; but his ſhip being attacked by the French near home, the head of the tree was ſhot off, but the ſtem being preſerved, put out ſeveral heads, which being taken off, produced ſo many plants.

CYCLAMEN. Lin. Gen. Plant. 184. Tourn. Inſt. R. H. 154. tab. 68. Cyclamen; in French, *Pain de Pourceau.* [Κυκλάμινος, of Κύκλος, *Gr.* a circle, becauſe the root of this plant is orbicular; it is called Sowbread, becauſe the root is round like a loaf, and the ſows eat it]. Sowbread.

The Characters are,

The flower hath a roundiſh permanent empalement of one leaf, divided into five parts at the top. It hath one petal with a globular tube, which is much larger than the empalement; the upper part is divided into five large ſegments, which are reflexed; it hath five ſmall ſtamina ſituated within the tube of the petal, terminated by acute ſummits, which are connected in the neck of the tube. It hath a roundiſh germen, ſupporting a ſlender ſtyle, which is longer than the ſtamina, and crowned by an acute ſtigma. The germen afterward becomes a globular fruit with one cell, opening in five parts at the top, incloſing many oval angular ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Cyclamen (*Europæum*) foliis haſtato-cordatis angulatis. *Cyclamen with ſpear-pointed heart-ſhaped leaves, which are angular.* Cyclamen hederæ folio. C. B. P. 306. *Sowbread with an Ivy leaf.*
2. Cyclamen (*Purpuraſcens*) foliis orbiculato-cordatis, infernè purpuraſcentibus. *Cyclamen with round heart-ſhaped leaves, purple on their under ſide.* Cyclamen orbiculato folio infernè purpuraſcente. C. B. P. 308. *Round-leaved Sowbread with a purple under ſide.*
3. Cyclamen (*Perſicum*) foliis cordatis ſerratis. *Cyclamen with ſawed heart-ſhaped leaves; or Perſian Cyclamen.*
4. Cyclamen (*Vernale*) foliis cordatis anguloſis integris. *Cyclamen with heart-ſhaped angular leaves which are entire.* Cyclamen hyeme & vere florens folio anguloſo amplo, flore albo, baſi purpurea, Perſicum dictum. H. R. Par.
5. Cyclamen (*Orbiculatum*) radice inæquali, foliis orbiculatis. *Cyclamen with an unequal root and round leaves.* Cyclamen radice caſtaneæ magnitudinis. C. B. P. 308.
6. Cyclamen (*Coum*) foliis orbiculatis planis, pediculis brevibus floribus minoribus. *Sowbread with orbicular plain leaves, ſhorter foot-ſtalks and ſmaller flowers.* Cyclamen Hyemale, orbiculatis foliis infernè rubentibus, purpuraſcente flore Coum Herbariorum. H. R. Par.

The firſt ſort is the moſt common in the Engliſh gardens. This grows naturally in Auſtria, Italy, and other parts of Europe, ſo will thrive in the open air in England, and is never killed by the froſt. It hath a large, orbicular, compreſſed root, from which ariſe a great number of angular heart-ſhaped leaves, upon ſingle foot-ſtalks, which are ſix or ſeven inches long; theſe leaves are marked with black in their middle; the flowers appear before the leaves, riſing immediately from the root, with long fleſhy foot-ſtalks; they appear in Auguſt and September, and ſoon after the leaves come out, continue growing all the winter and ſpring till May, when they begin to decay, and in June they are entirely dried up. After the flowers are fallen, the foot-ſtalks twiſt up like a ſcrew, incloſing the germen in the center, and lay down cloſe to the ſurface of the ground between the leaves, which ſerve as a protection to the ſeed. This germen becomes a round fleſhy ſeed-veſſel with one cell, incloſing ſeveral angular ſeeds. The ſeeds ripen in June, and ſhould be ſown in Auguſt. There are two varieties of this, one with a white and the other with a purpliſh flower, which appear at the ſame time.

The ſecond ſort flowers in autumn: this is at preſent very rare in England; the leaves of this ſort are large, orbicular, and heart-ſhaped at their baſe, and of a purple colour on their under ſide; the leaves and flowers of this come up from the root at the ſame time; the flowers are of a purpliſh colour, and their bottoms are of a deep red. It flowers late in the autumn, and requires protection from the froſt in winter.

The third ſort hath ſtiff heart-ſhaped leaves which are ſawed on their edges; theſe have ſtrong fleſhy foot-ſtalks near ſix inches long, of a purple colour, as are alſo the veins of the leaves on their under ſide, but the upper ſide is veined and marbled with white. The flowers riſe with ſingle foot-ſtalks from the root; theſe are pure white with a bright purple bottom; the petal is divided into nine ſegments to the bottom, which are twiſted and reflexed backward like the other ſorts. This flowers in March and April, and the ſeeds ripen in Auguſt.

The fourth ſort is commonly called the Perſian Cyclamen. This hath large, angular, heart-ſhaped leaves, whoſe edges are entire; they are veined and marbled with white on the upper ſide, and ſtand upon pretty long foot-ſtalks; the flowers are large, of a pale purple colour, with a bright red or purple bottom. Theſe appear in March and April, and the ſeeds ripen in Auguſt.

The fifth ſort hath a ſmall irregular root not larger than a Nutmeg; the leaves are orbicular and ſmall; the flowers are of a fleſh colour, ſmall, and have purple bottoms. They appear in the autumn, but rarely produce ſeeds in England.

The ſixth ſort is not ſo tender as the four laſt mentioned, ſo may be planted in warm borders, where, if they are covered in hard froſt, they will thrive and flower very well. This hath plain orbicular leaves, which have ſhorter and weaker foot-ſtalks than either of the other; their under ſides are very red in the beginning of winter, but that colour goes off in the ſpring; their upper ſides are ſmooth, of a lucid green, and ſpread open flat; whereas the other ſorts are hollowed, and reflexed at their baſe. The flowers are of a very bright purple colour, and appear in the middle of winter, at a time when there are few other flowers, which renders the plants more valuable. The ſeeds of this ſort ripen in the end of June.

There are ſeveral other varieties of this plant, which chiefly differ in the colour of their flowers, particularly among the Perſian kind, of which there is one with an entire white flower, which ſmells very ſweet; but as theſe are accidental variations, I have not enumerated them here, thoſe which are here mentioned being undoubtedly diſtinct ſpecies; for I have many years propagated them from ſeeds, and have not found them vary, nor have I heard that any other perſon has obſerved either of them alter farther than varying of their colours. Though Dr. Linnæus ſuppoſes them but one ſpecies, it is well known that the firſt ſort will endure the greateſt froſt in the open air, whereas all the Perſian ſorts are tender, and require ſhelter in winter.

All the ſorts are propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, in boxes or pots filled with light kitchen-garden earth, mixed with a little ſand, and covered about half an inch deep, placing them where they may have only the morning ſun till the beginning of September, when they may be removed to a warmer expoſure. Thoſe of the firſt ſort may be plunged into the ground cloſe to a ſouth wall, a pale, or Reed hedge, in October, where, if it ſhould be very ſevere froſt, it will be proper to cover them either with mats or Peaſe-haulm, but in common winters they will not require any covering. The pots or tubs in which the Perſian kinds are ſown, ſhould then be placed under a common hot-bed frame, where they may be protected from froſt and hard rains, but in mild weather the glaſſes may be taken off every day to admit freſh air to them. The firſt ſort will come up about Chriſtmas, if the ſeeds were ſown in Auguſt, and their leaves will continue green till May; and thoſe of the Perſian kinds will come up early in the ſpring, and continue green till June, when they will begin to decay; then they ſhould be removed to an eaſt aſpect, where they will have only the morning ſun, in which ſituation they may remain till the middle of Auguſt; during which time they ſhould have very little water, for then the roots are in an inactive ſtate, when much wet will rot them. The pots and tubs in which they are ſown, muſt be conſtantly kept clean from weeds; for if the weeds are permitted to grow, their roots will cloſely entangle with thoſe of the Cyclamen; ſo that in pulling out the weeds, the other roots will be drawn out with them. In the beginning of October, there ſhould be ſome freſh earth ſpread over the tubs or pots, which ſhould be removed again into ſhelter, in the ſame manner as before; and the following ſummer they muſt be managed alſo in the ſame way till their leaves decay, when they ſhould be carefully taken up, and thoſe of the firſt ſort placed in a warm border at three or four inches diſtance, but the other ſorts muſt be planted in pots to be ſheltered in winter.

The third, fourth, and fifth ſorts, are more impatient of cold and wet than the other three; theſe muſt conſtantly be preſerved in pots filled with ſandy light earth, and houſed in winter, but ſhould be placed near the glaſſes, where they may enjoy as much free open air as poſſible, when the weather will permit; for if they are crowded under other plants, and are kept too cloſe, they are very ſubject to mould and rot; nor ſhould they have much water in winter, which is alſo very injurious to them, but whenever they want water, it ſhould be given them ſparingly. In ſummer theſe plants may be expoſed to the open air, when their green leaves will decay; at which time you ſhould remove them to a place, where they may have the morning ſun until eleven o'clock; but during the time that the roots are deſtitute of leaves, they ſhould have very little water given them, becauſe at that ſeaſon they are not capable of diſcharging the moiſture. This is alſo the proper ſeaſon to tranſplant the roots, or to freſh earth them; and as the autumn comes on, that the heat decreaſes, they may be removed into places more expoſed to the ſun, where they may remain until October before they need be houſed.

Toward Chriſtmas, if the roots are in good health, the ſixth ſort will begin to flower, and continue producing freſh flowers till the middle of February, and theſe will be ſucceeded by the Perſian ſorts, which continue till May; but if you intend to have any ſeeds, you muſt let the pots be placed ſo as to receive a great ſhare of freſh air, for if their flowers are drawn up in the houſe, they ſeldom produce any ſeeds. Theſe ſeeds are ripe about July, when they ſhould be immediately ſown in pots or caſes of good light undunged earth, which ſhould be ſheltered in winter under a frame, and expoſed in ſummer in the ſame manner as is directed for the older roots, obſerving to remove them into pots at a wider diſtance when they are two years old; and ſo from time to time, as their roots increaſe in bulk, you muſt give them more room; and in about four or five years time they will begin to flower, when you ſhould let each root have a ſeparate pot, which at firſt may be ſmall, but when the roots are grown large, they muſt be put into larger pots.

Theſe ſorts have been planted under warm walls in the full ground, where, in mild winters they have done very well, but in ſevere froſt all thoſe roots have been deſtroyed; therefore, whenever theſe roots are planted in an open border, there ſhould be common hot-bed frames placed over them in winter, that in bad weather they may be covered to protect them from froſt: and where they are thus managed, the plants will produce more flowers, which will be much fairer than what are produced from the roots in the pots, and from theſe there may always be good ſeeds expected: therefore ſuch perſons who are curious in flowers, ſhould have a border framed over on purpoſe for theſe, the Guernſey and Belladonna Lilies, with ſome other of the curious bulbous-rooted flowers; in which border there may be many of theſe curious flowers cultivated, to more advantage than in any other method now practiſed.

CYDONIA. Tourn. Inſt. R. H. 632. tab. 405. Pyrus. Lin. Gen. Plant. 550. [ſo called from Cydon, a town of Crete, famous for this fruit.] The Quince-tree.

The CHARACTERS are,

The flower is compoſed of five large, roundiſh, concave petals, which are inſerted in the permanent empalement of one leaf. The germen is ſituated under the flower, and ſupports five ſlender ſtyles, crowned by ſingle ſtigmas; theſe are attended by near twenty ſtamina, which are inſerted in the empalement, but are not ſo long as the petals; the germen afterward becomes a pyramidal or roundiſh fruit, which is fleſhy, and divided into five cells, in which are lodged ſeveral hard kernels or ſeeds.

This genus of plants is ranged in the eighth ſection of Tournefort's twenty-firſt claſs, which includes the trees and ſhrubs with a Roſe flower, whoſe empalement becomes a fruit pregnant with hard ſeeds. Dr. Linnæus has joined this genus, and alſo the Apple to the Pear, making them only ſpecies of the ſame genus, to which the Quince is nearly allied by its characters, which the Apple is not. However, though the joining of the Quince to the Pear may be allowed in a ſyſtem of botany, yet in a book of gardening, it may not be quite ſo proper, therefore I have choſen to continue them under their former well known titles.

The SPECIES are,

1. CYDONIA (*Oblonga*) foliis oblongo-ovatis ſubtus tomentoſis, pomis oblongis baſi productis. *Quince-tree with oblong oval leaves, woolly on their under ſide, and an oblong fruit lengthened at the baſe.* Cydonia fructu oblongo læviori. Tourn. Inſt. R. H. 632.
2. CYDONIA (*Maliforma*) foliis ovatis, ſubtus tomentoſis, pomis rotundioribus. *Quince-tree with oval leaves, woolly on their under ſide, and a rounder fruit.* Cydonia fructu breviore & rotundiore. Tourn. Inſt. R. H. 633. *Commonly called the Apple Quince.*
3. CYDONIA (*Luſitanica*) foliis obverſè-ovatis ſubtus tomentoſis. *Quince-tree with obverſe oval leaves, woolly on their under ſide.* Cydonia latifolia Luſitanica. Tourn. Inſt. 633. *Broad-leaved Portugal Quince.*

There are ſome other varieties of this fruit which are propagated in fruit-gardens, and in the nurſeries for ſale, one of which is a ſoft eatable fruit; there is another with a very aſtringent fruit, and a third with a very ſmall fruit, cottony all over, and is ſcarce worth keeping: theſe I ſuppoſe to be ſeminal variations, but the three ſorts before enumerated, I take to be diſtinct ſpecies, having propagated them by ſeeds, and have not found them to vary.

The Portugal Quince is the moſt valuable, the pulp of it turning to a fine purple when ſtewed or baked, and becomes much ſofter and leſs auſtere than the others, ſo is much better for making of marmalade.

They are all eaſily propagated either by layers, ſuckers, or cuttings, which muſt be planted in a moiſt ſoil. Thoſe raiſed from ſuckers are ſeldom ſo well rooted as thoſe which are obtained from cuttings or layers, and are ſubject to produce ſuckers again in greater plenty, which is not ſo proper for fruit-bearing trees. The cuttings ſhould be planted early in the autumn, and in very dry weather muſt be often watered to encourage their rooting. The ſecond year after they ſhould be removed into a nurſery at three feet diſtance row from row, and one foot aſunder in the rows, where they muſt be managed as was directed for Apples. In two or three years time theſe trees will be fit to tranſplant, where they are to remain for good, which ſhould be either by the ſide of a ditch, river, or in ſome other moiſt place, where they will produce a greater plenty, and much larger fruit than in a dry ſoil; though thoſe in a dry ſoil will be better taſted, and earlier ripe. Theſe trees require very little pruning; the chief thing to be obſerved is, to keep their ſtems clear from ſuckers, and cut off ſuch branches as croſs each other; likewiſe all upright luxuriant ſhoots from the middle of the tree ſhould be taken entirely out, that the head may not be too much crowded with wood, which is of ill conſequence to all ſorts of fruit-trees. Theſe ſorts may alſo be propagated by budding or grafting upon ſtocks raiſed by cuttings, ſo that the beſt ſorts may be cultivated in greater plenty this way, than by any other method; and theſe trees will bear fruit much ſooner, and be more fruitful than thoſe which come from ſuckers or layers.

Theſe are alſo in great eſteem for ſtocks to graft and bud Pears on, which for ſummer and autumn fruits are a great improvement to them, eſpecially thoſe deſigned for walls and eſpaliers; for the trees upon theſe ſtocks do not ſhoot ſo vigorouſly as thoſe upon free ſtocks, and therefore may be kept in leſs compaſs, and are ſooner diſpoſed to bear fruit: but hard winter fruits do not ſucceed ſo well upon theſe ſtocks, their fruit being very ſubject to crack, and are commonly ſtony, eſpecially all the breaking Pears; therefore theſe ſtocks are only proper for the melting Pears, and for a moiſt ſoil. The beſt ſtocks are thoſe which are raiſed from cuttings or layers.

As the Pear will take upon the Quince by grafting or budding, and ſo vice verſâ, we may conclude there is a near alliance between them; but as neither of theſe will take upon the Apple, nor that upon either of theſe, ſo we ſhould ſeparate them under different genera, as will be further mentioned under the article MALUS.

CYNANCHUM. Lin. Gen. Plant. 268. Apocynum. Tourn. Inſt. R. H. 91. Periploca. Tourn. Inſt. 93. tab. 22.

The CHARACTERS are,

The flower hath one petal; it hath ſcarce any tube, but is ſpread open, plain, and divided into five parts; this hath a ſmall, erect, permanent empalement of one leaf, divided into five parts; the nectarium, which is ſituated in the center of the flower, is erect, cylindrical, and the length of the petal. It hath five ſtamina which are parallel to the nectarium, and of the ſame length, terminated by ſummits which reach to the mouth of the petal. It hath an oblong bifid germen, with ſcarce any ſtyle, crowned by two obtuſe ſtigmas; the empalement becomes a capſule with two oblong pointed leaves, having a cell which opens longitudinally, and is filled with ſeeds lying over each other imbricatim, and are crowned with long down.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, the flower having five ſtamina and two ſtyles.

The SPECIES are,

1. CYNANCHUM (*Acutum*) caule volubili herbaceo, foliis cordato-oblongis glabris. Hort. Cliff. 79. *Cynanchum with a twining herbaceous ſtalk, and oblong, ſmooth, heart-ſhaped leaves.* Periploca Monſpeliaca foliis acutioribus. Tourn. Inſt. 93. *Commonly called Montpelier Scammony.*
2. CYNANCHUM (*Monſpeliacum*) caule volubili herbaceo, foliis reniformi-cordatis acutis. Hort. Cliff. 79. *Cynanchum with a twining herbaceous ſtalk, and kidney, heart-ſhaped, pointed leaves.* Periploca Monſpeliaca

foliis rotundioribus. Tourn. Inſt. R. H. 93. *Round-leaved Montpelier Scammony.*

3. Cynanchum (*Suberoſum*) caule volubili infernè ſuberoſo fiſſo, foliis cordatis acuminatis. Hort. Cliff. 79. *Cynanchum with a twining fungous ſtalk, having fiſſures on the under ſide, and heart-ſhaped pointed leaves.* Periploca Caroliniensis, flore minore ſtellato. Hort. Elth. 300.
4. Cynanchum (*Hirtum*) caule volubili fruticoſo, infernè ſuberoſo fiſſo, foliis ovato-cordatis. Hort. Cliff. 79. *Cynanchum with a ſhrubby twining ſtalk, whoſe lower part is fungous, having fiſſures, and oval heart-ſhaped leaves.* Periploca ſcandens, folio citri, fructu maximo. Plum. Cat. 2.
5. Cynanchum (*Erectum*) caule erecto divaricato, foliis cordatis glabris. Hort. Cliff. 79. *Cynanchum with an upright divaricated ſtalk, and heart-ſhaped ſmooth leaves.* Apocynum folio ſubrotundo. C. B. P. 302.
6. Cynanchum (*Aſperum*) caule volubili fruticoſo, foliis cordatis acutis aſperis, floribus lateralibus. *Cynanchum with a twining ſhrubby ſtalk, heart-ſhaped, pointed, rough leaves, and flowers growing from the ſides of the ſtalks.* Apocynum ſcandens foliis cordatis aſperis, floribus amplis patulis luteis. Houſt. MSS.

The firſt and ſecond ſorts grow naturally about Montpelier; theſe have perennial creeping roots, but annual ſtalks, which decay to the root every autumn, and riſe afreſh in the ſpring; theſe ſtalks twiſt themſelves like Hops, round whatever plants are near them, and riſe to the height of ſix or eight feet; the firſt of theſe is garniſhed with oblong, heart-ſhaped, ſmooth leaves, ending in acute points, and are placed by pairs oppoſite on long foot-ſtalks; the flowers come out in ſmall bunches from the wings of the leaves; they are of a dirty white colour, and divided into five acute ſegments, which ſpread open in form of a ſtar. Theſe appear in June and July, but are not ſucceeded by any ſeed-veſſels in England, which may be occaſioned by their roots creeping ſo far under ground; for moſt of thoſe plants which propagate themſelves ſo much by their roots, become barren of ſeeds, eſpecially if their roots have full liberty to extend.

The ſecond ſort differs from the firſt in the ſhape of its leaves, which are broader and rounder at their baſe. The roots of this ſort are very thick, running deep into the ground, and extend themſelves far on every ſide; ſo that where this plant hath got poſſeſſion of the ground it is not eaſily extirpated, for every piece of the root will ſhoot, which may happen to be left in the ground. Both theſe plants abound with a milky juice like the Spurge, which iſſues out wherever they are broken; and this milky juice when concreted, has been frequently ſold for ſcammony.

Theſe plants propagate too faſt by their creeping roots when they are admitted into gardens, ſo few people care to have them: the roots may be tranſplanted any time after their ſtalks decay, till they begin to ſhoot in the ſpring.

The third ſort grows naturally in Carolina, from whence the ſeeds were brought to England; this is a perennial plant with twining hairy ſtalks, which, if ſupported, will riſe ſix or ſeven feet high; the lower part of the ſtalks are covered with a thick fungous bark, ſomewhat like cork, which is full of fiſſures; theſe ſtalks are ſlender, and garniſhed at each joint with two oblong, heart-ſhaped, pointed leaves, ſtanding on long hairy foot-ſtalks. The flowers are produced in ſmall bunches at the wings of the leaves, theſe are ſtar-ſhaped and green when they firſt appear, but afterward fade to a worn-out purple colour. They appear in July and Auguſt, but are not ſucceeded by ſeeds in England.

This plant will live in the open air in England, if it is planted in a dry ſoil and warm ſituation. It may be propagated by laying down ſome of the young ſhoots about Midſummer, which, if they are now and then refreſhed with water, will put out roots, ſo may be tranſplanted in the autumn, where they are deſigned to remain. The roots of this plant ſhould be covered in winter with ſome rotten tan to keep out the froſt, otherwiſe in ſevere winters they are liable to be deſtroyed.

The fourth ſort grows naturally in Jamaica, from whence the ſeeds were ſent me by the late Dr. Houſtoun; this riſes with a twining ſtalk to the height of twenty feet or upward, provided it hath ſupport; the lower part of the ſtalks are covered with a thick fungous bark, full of fiſſures, which gape open; the leaves are oblong and ſmooth, and placed by pairs oppoſite, ſtanding on long foot-ſtalks: the flowers are produced from the wings of the leaves in ſmall bunches, they are ſtar-ſhaped, and are of a yellowiſh green colour, but are not ſucceeded by pods in England.

This ſort is tender, ſo will not thrive in this country unleſs it is placed in a warm ſtove, and requires the ſame treatment as other tender plants from the ſame country; and as it abounds with a milky juice, ſo the plants muſt have little water in winter. This may be propagated by laying down of the young ſhoots, which in three or four months will put out roots, and may then be tranſplanted into pots filled with light ſandy earth, and plunged into the tan-bed in the bark-ſtove, where the plants ſhould continue all the year.

The fifth ſort grows naturally in Syria; this is a perennial plant, which riſes with ſlender upright ſtalks about three feet high, garniſhed with broad, ſmooth, heart-ſhaped leaves ending in points, placed oppoſite; the flowers come out from the wings of the leaves in ſmall bunches, ſtanding on branching foot-ſtalks; theſe are ſmall and white, greatly reſembling thoſe of the common white Aſclepias, or Swallow-wort, and are ſucceeded by oblong taper pods, filled with flat ſeeds crowned with down, but theſe rarely ripen in this country.

It is propagated by parting of the root; the beſt time for doing of this or tranſplanting of the roots, is in the ſpring, before they ſhoot: this requires a warm ſituation, otherwiſe it will not live abroad in England.

The ſixth ſort grows naturally at La Vera Cruz in New Spain, from whence the ſeeds were ſent me by the late Dr. Houſtoun; this hath a ſhrubby twining ſtalk, which twiſts about whatever prop is near it, and riſes to the height of twenty feet or upward; the ſtalks are very ſlender, and are armed with ſmall ſtinging hairs, and garniſhed with broad heart-ſhaped leaves, which end in acute points; theſe are placed by pairs at each joint, which are far diſtant, and have ſlender foot-ſtalks; they are covered with rough hairs on their under ſide; the flowers are produced in ſmall cluſters, ſitting cloſe to the ſide of the ſtalks; they are pretty large, yellow, and ſtar-ſhaped, ſpreading open to the bottom; they are ſucceeded by long ſwelling pods, filled with flat ſeeds lying imbricatim, which are crowned with long down.

This ſort is tender, ſo requires the ſame treatment as the fourth, and is propagated the ſame way.

CYNARA. Lin. Gen. Plant. 835. Cinara. Tourn. Inſt. R. H. 442. tab. 254. Artichoke, in French *Artichaut.*

The Characters are,

It hath a compound flower, made up of many hermaphrodite florets, which are included in one common ſcaly empalement, which is ſwollen in the bottom. The florets are tubulous, equal, and uniform, divided at the top into five narrow ſegments. Theſe have five ſhort hairy ſtamina, terminated by cylindrical ſummits, which have five indentures; at the bottom of each is ſituated an oval germen, ſupporting an oblong ſtyle, crowned by an oblong indented ſtigma. The germen afterward becomes a ſingle, oblong, compreſſed, four-cornered ſeed, crowned with long hairy down.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia æqualis; the plants of this claſs and ſection have only hermaphrodite florets which are fruitful.

The Species are,

1. Cynara (*Scolymus*) foliis ſubſpinoſis, pinnatis indiviſiſque, calycinis ſquamis ovatis. Lin. Sp. Plant. 827. *Artichoke with ſpiny leaves which are winged and undivided, and an oval ſcaly empalement.* Cynara hortenſis aculeata. C. B. P. 383. *The green or French Artichoke.*
2. Cynara (*Hortenſis*) foliis pinnatis inermibus, calycinis ſquamis obtuſis emarginatis. *Artichoke with winged leaves having no ſpines, and obtuſe indented ſcales to the empalement.* Cynara hortenſis foliis non aculeatis. C. B. P. 383. *The Globe Artichoke.*
3. Cynara (*Cardunculus*) foliis ſpinoſis, omnibus pinnatifidis, calycinis ſquamis ovatis. Lin. Sp. Plant. 827. *Cynara with prickly leaves which all end in winged points, and oval ſcales to the empalement.* Cynara ſpinoſa, cujus pediculi eſitantur. C. B. P. 383. *The Cardoon, in French* Chardon.
4. Cynara (*Humilis*) foliis ſpinoſis, pinnatifidis, ſubtus tomentoſis, calycibus ſquamis ſubulatis. Lin. Sp. Plant. 828. *Cynara with winged prickly leaves, woolly on their under ſide, and awl-ſhaped ſcales to the empalement.* Cynara ſylveſtris Bœtica. Cluſ. Cur. Poſt. 15. *Wild Artichoke of Spain.*

The firſt ſort is commonly known here by the title of French Artichoke, being the ſort which is moſt commonly cultivated in France, and is the only kind in Guernſey and Jerſey; the leaves of this ſort are terminated by ſhort ſpines, the head is oval, and the ſcales do not turn inward at the top like thoſe of the Globe Artichoke, the heads are alſo of a green colour; the bottoms of theſe are not near ſo thick of fleſh as thoſe of the Globe, and they have a perfumed taſte, which to many perſons is very diſagreeable; ſo that it is ſeldom cultivated in the gardens near London, where the Globe or red Artichoke is the only ſort in eſteem. The leaves of this are not prickly, the head is globular, a little compreſſed at the top, the ſcales lie cloſe over each other, and their ends turn inward, ſo as to cloſely cover the middle.

The culture of theſe having been fully treated under the article Artichoke, the reader is deſired to turn to that, to avoid repetition.

The Chardon, or Cardoon, is propagated in the kitchen gardens to ſupply the markets; this is annually raiſed from ſeeds, which ſhould be ſown upon a bed of light earth in March; and when the plants come up, they ſhould be thinned where they are too cloſe; and if the plants are wanted, thoſe which are drawn out may be tranſplanted into a bed at about three or four inches diſtance, where they ſhould remain till they are tranſplanted out for good. Theſe young plants muſt be kept clean from weeds, and in the beginning of June they muſt be tranſplanted out, on a moiſt rich ſpot of ground at about four feet aſunder every way; the ground ſhould be well dug before they are planted, and the plants ſhould be well watered until they have taken new root, after which the ground muſt be kept very clean from weeds, to encourage the growth of the plants; and as they advance in height, there ſhould be ſome earth drawn up about each plant; and when they are fully grown, their leaves ſhould be cloſely tied up with a hay-band, and the earth drawn up in hills about each plant, almoſt to their tops, being careful to keep the earth from falling between the leaves, which may occaſion the rotting of the plants. The earth ſhould be ſmoothed over the ſurface that the wet may run off, and not fall into the center of the plants, which will alſo cauſe them to rot; in about eight or ten weeks after the plants have been thus earthed, they will be blanched enough for uſe; ſo that if a ſucceſſion of them are wanted for the table, there ſhould be but few plants earthed up at the ſame time; but once in a fortnight there may be a part of them earthed, in proportion to the quantity deſired.

Toward the middle, or latter end of November, if the froſt ſhould be ſevere, it will be proper to cover the tops of thoſe plants which remain with Peaſehaulm or ſtraw, to prevent the froſt from penetrating to the tender leaves, which frequently pinches them where there is not this covering, but this ſhould be taken off again in mild weather; if this care is taken, the plants may be preſerved for uſe moſt part of the winter.

If a few of the plants are planted out in a warm ſituation to ſtand for ſeed, they ſhould not be blanched, but only in very hard froſt ſome light litter, or Peaſehaulm, may be laid round them to keep out froſt, which ſhould be removed in the ſpring, and the ground gently dug between the plants, which will not only deſtroy the weeds, but alſo encourage the roots of the plants to ſhoot out on every ſide, whereby their ſtems will be ſtronger; theſe will flower about the beginning of July, and if the ſeaſon proves dry, their ſeeds will ripen in September; but in cold wet ſeaſons, theſe ſeeds will not come to maturity in England.

The fourth ſort grows naturally in Spain, and alſo on the African ſhore, and is preſerved in gardens for the ſake of variety; this is very like the third ſort, but the ſtems of the leaves are much ſmaller, and do not grow more than half ſo high. The heads of this have ſome reſemblance to thoſe of the French Artichoke, but have no meat, or fleſhy ſubſtance in their bottoms: this may be planted in the ſame manner as the third ſort, at about three or four feet apart, and will require no other treatment, than the keeping them clean from weeds; the ſecond year they will flower, and, if the ſeaſon proves dry, they will ripen their ſeeds in September, and the plants generally decay the following winter, eſpecially if the winter proves ſevere, unleſs they are covered.

CYNOGLOSSUM. Lin. Gen. Plant. 168. Tourn. Inſt. R. H. 139. tab. 57. Omphalodes. Tourn. 140. tab. 59. [Κυνόγλωσσον, of Κυνός, a dog, and Γλῶσσα, *Gr.* the tongue, ſo called becauſe the leaves of this plant reſemble a dog's tongue.] Hounds Tongue, in French, *Langue de Chien.*

The Characters are,

It hath a funnel-ſhaped flower of one leaf, with a long tube, and a ſhort brim, which is ſlightly cut into five parts, and is ſhut up at the chaps; this hath an oblong permanent empalement, cut into five acute ſegments. The flower hath five ſhort ſtamina in the chaps of the petal, terminated by roundiſh ſummits, and at the bottom of the tube are ſituated four germen, between which ariſes a permanent ſtyle the length of the ſtamina, crowned by an indented ſtigma; the empalement afterward becomes four capſules, incloſing four oval ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Cynoglossum (*Officinale*) ſtaminibus corollâ brevioribus, foliis lato-lanceolatis tomentoſis ſeſſilibus. Lin. Sp. Plant. 134. *Hounds Tongue with ſtamina ſhorter than the petal, and broad ſpear-ſhaped leaves, which are woolly, ſitting cloſe to the ſtalk.* Cynogloſſum majus vulgare. C. B. P. 257. *Common greater Hounds Tongue.*
2. Cynoglossum (*Appeninum*) ſtaminibus corollam æquantibus. Hort. Upſal. 33. *Hounds Tongue with ſtamina equalling the petal.* Cynogloſſum montanum maximum. Tourn. Inſt. R. H. 139.
3. Cynoglossum (*Creticum*) foliis oblongis tomentoſis, amplexicaulibus, caule ramoſo, ſpicis florum longiſſimis ſparſis. *Hounds Tongue with oblong woolly leaves embracing the ſtalks, a branching ſtalk, and very long looſe ſpikes to the flowers.* Cynogloſſum Creticum latifolium fœtidum. C. B. P. 257.
4. Cynoglossum (*Cheirifolium*) corollis calyce duplo longioribus, foliis lanceolatis. Prod. Leyd. 406. *Hounds Tongue having a petal twice the length of the empalement, and ſpear-ſhaped leaves.* Cynogloſſum Creticum, argenteo anguſto folio. C. B. P. 257.
5. Cynoglossum (*Virginianum*) foliis amplexicaulibus ovatis. Lin. Sp. 193. *Hounds Tongue with oval leaves which embrace the ſtalk.* Cynogloſſum Virginianum flore minimo albo. Baniſter. Cat.

6. Cynoglossum (*Luſitanicum*) foliis lineari lanceolatis ſcabris. Lin. Sp. 193. *Hounds Tongue with linear, ſpear-ſhaped, rough leaves.* Omphalodes Luſitanica elatior Cynogloſſi folio. Tourn. Inſt. R. H. 140.
7. Cynoglossum (*Linifolium*) foliis lineari-lanceolatis glabris. Hort. Cliff. 47. *Hounds Tongue with ſmooth, narrow, ſpear-ſhaped leaves.* Omphalodes Luſitanica lini folio. Tourn. Inſt. 140. *Commonly called Venus Navelwort.*
8. Cynoglossum (*Omphalodes*) repens, foliis radicalibus cordatis. Hort. Cliff. 47. *Creeping Hounds Tongue, whoſe lower leaves are heart-ſhaped.* Omphalodes pumila verna ſymphyti folio. Tourn. Inſt. 140.

The firſt ſort grows naturally by the ſide of hedges and foot-ways in many parts of England, ſo is ſeldom admitted into gardens; the roots of this ſort are uſed in medicine, which are gathered by the herb-folks in the fields. The leaves of this plant have a ſtrong odour, like that of mice in a trap. It flowers in June, and the ſeeds ripen in autumn.

The ſecond ſort grows naturally on the Apennine mountains; the leaves of this ſort are much larger, the petal of the flower is ſhorter, and the plants grow taller than thoſe of the firſt, and come earlier to flower in the ſpring; this is equally hardy as the common ſort, and where the ſeeds are permitted to ſcatter, there will be plenty of the plants ariſe without care.

The third ſort grows naturally in Andaluſia, I received the ſeeds of this from Gibraltar; this hath a tall branching ſtalk, garniſhed with oblong woolly leaves, which embrace the ſtalk with their baſe. The flowers are produced in looſe ſpikes, which come out from the ſide of the ſtalk, and are from ſix to eight inches long, the flowers are thinly placed on one ſide; theſe are blue, ſtriped with red, and appear in June. The ſeeds ripen in autumn, ſoon after which the root decays.

The fourth ſort grows naturally in Spain, and alſo in the iſland of Crete; I received this from Gibraltar, with thoſe of the former; this riſes with an upright ſtalk little more than a foot high, garniſhed with long, narrow, ſilvery leaves, having no foot-ſtalks. The flowers are produced from the ſide, and at the top of the ſtalks, which are but thinly diſperſed on the ſide, but at the top of the ſtalk are in ſmall cluſters; they are of a deep purple colour, and much longer than the empalement; theſe are ſucceeded by four broad buckler-ſhaped ſeeds, which are rough. It flowers in June, and the ſeeds ripen in autumn, ſoon after which the roots generally periſh.

The fifth ſort grows naturally in Virginia, and in other northern parts of America; this riſes with an upright branching ſtalk near four feet high. The ſtalks and leaves are covered with rough hairs, the branches are ſpread out on every ſide, and are but thinly garniſhed with leaves, from three to near four inches in length, and little more than one inch broad in the middle, gradually leſſening to both ends; they embrace the ſtalks with their baſe, and are placed alternate; the flowers grow ſcatteringly toward the end of the branches; theſe are ſmall and white; they appear in June, and are ſucceeded by four ſmall ſeeds, which ripen in autumn, and then the plants decay.

The ſixth ſort grows naturally in Portugal, where it was firſt diſtinguiſhed from the ſeventh by Dr. Tournefort. The ſeventh ſort had been long before that cultivated in the gardens for ornament, by the title of Venus Navelwort, but of late years that has been almoſt loſt; and the ſixth ſort is now generally preſerved in the Engliſh gardens, and the ſeeds are ſold by the ſeedſmen under that title, and is a much larger plant than the other, ſo makes a better appearance. The leaves of the ſixth ſort are broad at their baſe, and are gradually narrowed to the end; they are ſlightly covered with hairs. The ſtalks grow nine or ten inches high, and divide into many branches, each being terminated by a long looſe ſpike of white flowers, ſtanding on ſeparate foot-ſtalks, which are ſucceeded by four umbilicated ſeeds, from whence it had the title of Navelwort.

The ſeventh ſort ſeldom riſes more than five or ſix inches high; the ſtalks do not branch near ſo much as thoſe of the ſixth. The leaves are very narrow and long, of a grayiſh colour, and ſmooth. The flowers grow in ſhort looſe panicles at the end of the branches; theſe are white, but ſmaller than thoſe of the other ſort, and are ſucceeded by ſeeds of the ſame form. This plant was formerly titled Linum Umbillicatim, i. e. *umbilicated Flax*, from the leaves having ſome appearance of Flax, and the ſeeds having a hollow like a navel.

Theſe are both annual plants, and have been commonly ſown in gardens, with other low annual flowers, to adorn the borders of the flower-garden; but theſe ſhould be ſown in autumn, for thoſe which are ſown in the ſpring often fail, eſpecially in dry ſeaſons; and the autumnal plants always grow much larger than thoſe which ariſe from the ſpring ſowing, and come to flower earlier in the year. The ſeeds ſhould be ſown where the plants are deſigned to remain, for they do not bear tranſplanting, unleſs it is performed while they are young. The plants require no other culture but to be thinned where they are too cloſe, and kept clean from weeds. They flower in June and July, and the autumnal plants come a month earlier; their ſeeds ripen in autumn.

The eighth ſort is a low perennial plant, which grows naturally in the woods of Spain and Portugal, where it uſually flowers about Chriſtmas; this hath trailing branches, which put out roots from their joints, whereby it propagates very faſt. The leaves are heart-ſhaped, of a bright green colour, and ſtand upon long ſlender foot-ſtalks. The flowers grow in looſe panicles, which ariſe from the diviſions of the ſtalk; they are ſhaped like thoſe of Borage, but are ſmaller, and of a lively blue colour; they appear in March and April, and in a cool ſhady ſituation continue great part of May, but are rarely ſucceeded by ſeeds; but the plants propagate themſelves ſo faſt by their trailing branches, as to render the cultivation of them by ſeeds unneceſſary. It delights in a moiſt cool ſituation.

CYPERUS, Cypreſs Graſs.

There are about twenty ſpecies of this genus known, ſome of which grow naturally in England, but the far greateſt number are natives of America, where they grow in moiſt ſqualid places; and as there are not above two or three ſpecies which are preſerved in gardens, ſo it will be to little purpoſe to enumerate the others.

The Species are,

1. Cyperus (*Longus*) culmo triquetro folioſo, umbella folioſo ſupra decompoſita, pedunculis nudis, ſpicis alternis. Prod. Leyd. 50. *Cypreſs with a three-cornered ſtalk, an umbel with many leaves, alternate ſpikes on naked foot-ſtalks. Long-rooted Cypreſs of the ſhops.*
2. Cyperus (*Rotundus*) culmo triquetro ſubnudo, umbella decompoſita, ſpicis alternis linearibus. Flor. Zeyl. 36. *Cypreſs with a three-cornered naked ſtalk, a decompounded umbel, and linear ſpikes placed alternate. Round-rooted Cypreſs of the ſhops.*

The firſt ſort grows naturally in France and Italy, from whence the plant was brought for medicinal uſe, but at preſent it is very ſeldom uſed in England. The roots of this ſort are compoſed of many ſtrong fleſhy fibres which root deep in the ground, ſending up every ſpring a great number of graſſy three-cornered leaves near two feet long; the flower-ſtalks are triangular, nearly of the ſame length, ſupporting an umbel at the top, having many narrow triangular leaves under it; the ſpikes of the umbel are like thoſe of ſome ſorts of graſs, but the ſeeds rarely ripen in England; ſo the plant is here propagated by dividing the root in the ſpring, and if planted in a warm ſituation, will thrive here in the open air.

The ſecond ſort is tenderer than the firſt, ſo the round compreſſed roots ſhould be planted in pots, and ſheltered in winter.

CYPRIPEDIUM. Lin. Gen. Plant. 906. Calceolus. Tourn. Inſt. R. H. 436. tab. 249. Ladies Slipper, in French, *Sabot*.

The CHARACTERS are,

It hath a ſimple ſpadix. The germen ſits under the flower, which is covered with a ſpatha or ſheath. The flowers have four or five narrow ſpear-ſhaped petals, which expand. The nectarium, which is ſituated between the petals, is ſwollen and hollow, in ſhape of a ſhoe, or ſlipper. It hath two ſhort ſtamina which ſit upon the pointal, and are terminated by erect ſummits, which join to the upper lip of the nectarium; below the flower is fixed a ſlender contorted germen, ſupporting a ſhort ſtyle, adhering to the upper lip of the nectarium, crowned by an obſolete ſtigma. The germen afterward becomes an oval blunt capſule with three corners, having three furrows, three valves, and one cell, which is filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's twentieth claſs, intitled Gynandria Diandria, the plants of this claſs and ſection have two ſtamina fixed to the ſtyle.

The SPECIES are,

1. CYPRIPEDIUM (*Calceolus*) radicibus fibroſis, foliis ovato-lanceolatis caulinis. Act. Upſal. 1740. *Ladies Slipper with fibrous roots, the leaves on the ſtalks oval and ſpear-ſhaped.* Calceolus Mariæ. Ger. 359. *Our Lady's Slipper.*
2. CYPRIPEDIUM (*Bulboſum*) ſcapo unifloro, foliis oblongis glabris petalis anguſtis acuminatis. *Ladies Slipper with one flower in a ſheath, oblong ſmooth leaves, and very narrow pointed petals.* Calceolus Mariæ luteus. Mor. H. R. Bloſs. *Yellow Ladies Slipper.*
3. CYPRIPEDIUM (*Hirſutum*) foliis oblongo-ovatis venoſis hirſutis, flore maximo. *Ladies Slipper with oblong, oval, veined leaves, which are hairy, and a very large flower.* Calceolus flore majore. Tourn. Inſt. R. H. 437. *Ladies Slipper with a larger flower.*

The firſt ſort grows naturally in ſome ſhady woods in the north of England. I found it in the park of Borough-Hall, in Lancaſhire, the ſeat of the late Robert Fenwick, Eſq; It hath a root compoſed of many fleſhy fibres, from which ariſe, in the ſpring, two, three, or more ſtalks, in proportion to the ſtrength of the root; theſe grow nine or ten inches high, and are garniſhed with oval ſpear-ſhaped leaves, having a few longitudinal veins; in the boſom of one of the upper leaves is incloſed the flower-bud, which is ſupported by a ſlender foot-ſtalk, which generally turns a little bud on one ſide. The flower hath four dark purple petals, placed in form of a croſs, which ſpread wide open. In the center is ſituated the large hollow nectarium, almoſt as large as a bird's egg, ſhaped like a wooden ſhoe, of a pale yellowiſh colour, with a few broken ſtreaks; the opening is covered with two ears; the upper one is tender, white, and ſpotted with purple; the lower is thick, and of an herbaceous colour. The flowers appear about the end of May, and the ſtalks decay early in autumn.

The ſecond ſort grows naturally in Virginia, and other parts of North America; this hath longer and ſmoother leaves than the former. The two ſide petals of the flower are long, narrow, and terminate in acute points, and are wreathed, or undulated on their ſides. The nectarium is oblong, and narrower than in the firſt ſort, and is yellow, ſpotted with browniſh red. The ſtalks riſe near a foot and a half high.

The third ſort grows naturally in America, where the inhabitants call it Moccaſin Flower; this riſes a foot and a half high. The leaves are of an oblong oval form, and are deeply veined. The flower is large, of a reddiſh brown colour, marked with a few purple veins. This ſort flowers in the end of May.

All theſe ſorts are with difficulty preſerved in gardens; they muſt be planted in a loamy ſoil, and in a ſituation where they may have the morning ſun only. They muſt be procured from the places where they naturally grow, for they cannot be propagated in gardens. The roots ſhould be ſeldom removed, for tranſplanting them prevents their flowering.

CYSTICAPNOS. See FUMARIA.

CYTISO-GENISTA. See SPARTIUM.

CYTISUS. Lin. Gen. Plant. 785. Tourn. Inſt. R. H. 647. tab. 416. [ſo called from Cythos, an iſland in the Archipelago, where it grew in great plenty.] Baſe-tree Trefoil, in French, *Citiſe*.

The CHARACTERS are,

It hath a butterfly flower, with a ſhort bell-ſhaped empalement of one leaf, divided in two lips, the upper being bifid and acute, the under indented in three parts. The ſtandard of the flower is riſing, oval, and reflexed on the ſides. The wings are obtuſe, erect, and the length of the ſtandard. The keel is bellied and acute. It hath ten ſtamina, nine joined, and one ſtanding ſeparate, terminated by riſing ſummits. It hath an oblong germen, ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes an oblong blunt pod, narrow at their baſe, filled with kidney-ſhaped flatted ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, from the flowers having ten ſtamina divided into two bodies.

The SPECIES are,

1. CYTISUS (*Laburnum*) foliis oblongo-ovatis, racemis brevioribus pendulis, caule arboreo. *Cytiſus with oblong oval leaves, ſhort ſpikes of flowers hanging downward, and a tree-like ſtalk.* Cytiſus Alpinus latifolius, flore racemoſo pendulo. Tourn. Inſt. R. H. 648. *Commonly called Laburnum.*
2. CYTISUS (*Alpinus*) foliis ovato-lanceolatis, racemis longioribus pendulis, caule fruticoſo. *Cytiſus with oval ſpear-ſhaped leaves, long pendulous bunches of flowers, and a ſhrubby ſtalk.* Cytiſus Alpinus anguſtifolius, flore racemoſo pendulo longiore. Tourn. Inſt. R. H. 648. *Commonly called long-ſpiked Laburnum.*
3. CYTISUS (*Nigricans*) racemis ſimplicibus erectis, foliolis ovato-oblongis. Hort. Cliff. 354. *Cytiſus with ſingle erect bunches of flowers, and oval oblong leaves.* Cytiſus glaber nigricans. C. B. P. 390. *Black ſmooth Cytiſus.*
4. CYTISUS (*Seſſilibus*) racemis erectis, calycibus bracteâ triplici auctis, foliis floralibus ſeſſilibus. Lin. Sp. Plant. 739. *Cytiſus with erect bunches of flowers, three laminæ under the empalement, and the leaves on the flower branches ſitting cloſe.* Cytiſus glabris, foliis ſubrotundis, pediculis breviſſimis. C. B. P. 390. *Commonly called by the gardeners,* Cytiſus ſecundus Cluſii.
5. CYTISUS (*Hirſutis*) pedunculis ſimplicibus lateralibus, calycibus hirſutis trifidis ventricoſo-oblongis. Hort. Upſal. 211. *Cytiſus with ſingle foot-ſtalks on the ſide of the branches, trifid hairy empalements, oblong and bellied.* Cytiſus incanus ſiliqua longiore. C. B. P. 390. *Commonly called hairy, or Evergreen Cytiſus of Naples.*
6. CYTISUS (*Argenteus*) floribus ſeſſilibus, foliis tomentoſis, caulibus herbaceis. Lin. Sp. Plant. 740. *Cytiſus with flowers ſitting cloſe to the branches, woolly leaves, and an herbaceous ſtalk.* Cytiſus humilis argenteus anguſtifolius. Tourn. Inſt. 648.
7. CYTISUS (*Supinus*) floribus umbellatis terminalibus, ramis decumbentibus, foliolis ovatis. Lin. Sp. 1042. *Low Cytiſus with umbellated flowers terminating the branches, which are trailing, and oval leaves.* Cytiſus ſupinus foliis infra & ſiliquis molli lanugine pubeſcentibus. C. B. P. 390.
8. CYTISUS (*Auſtriacus*) floribus umbellatis terminalibus, caulibus erectis foliolis lanceolatis. Lin. Sp. 1042. *Cytiſus with umbellated flowers terminating the branches, erect ſtalks and ſpear-ſhaped leaves.* Cytiſus floribus capitatis, foliolis ovato-oblongis, caule fruticoſo. Dict. Hort. *Commonly called Siberian Cytiſus.*
9. CYTISUS (*Æthiopicus*) racemis lateralibus ſtrictis, ramis angulatis, foliolis cuneiformibus. Lin. Sp. 1042. *Cytiſus with narrow bunches of flowers proceeding from the ſide of the branches, which are angular, and wedge-ſhaped leaves.* Cytiſus Æthiopicus, ſubrotundis incanis minoribus foliis, floribus parvis luteis. Pluk. Alm. 128.
10. CYTISUS (*Græcus*) foliis ſimplicibus lanceolato-linearibus, ramis angulatis. Lin. Sp. 1043. *Cytiſus with ſingle, linear, ſpear-ſhaped leaves, and angular branches.* Barba Jovis linariæ folio, flore luteo parvo. Tourn. Cor. 44.

11. Cytiſus (*Cayan*) racemis axillaribus erectis, foliolis ſublanceolatis tomentoſis, intermedio longiùs petiolato. Flor. Zeyl. 357. *Cytiſus with erect ſpikes of flowers proceeding from the ſides of the branches, and ſpear-ſhaped leaves which are woolly, the foot-ſtalk of the middle one being the longeſt.* Cytiſus arboreſcens, fructu eduli albo. Plum. Cat. 19. *Commonly called Pidgeon Pea in America.*

The firſt ſort is the common broad-leaved Laburnum, which was formerly in greater plenty in the Engliſh gardens than at preſent; for ſince the ſecond ſort hath been introduced, it has almoſt turned this out; the ſpikes of flowers being much longer, they make a finer appearance when they are in flower, which has occaſioned their being more generally cultivated; but the firſt grows to be the largeſt tree, and the wood of it is very hard, of a fine colour, and will poliſh very well; it approaches near to green Ebony, ſo is by the French titled Ebony of the Alps, and is there uſed for many kinds of furniture; but in England there are few of theſe trees which have been ſuffered to ſtand long enough to arrive to any conſiderable ſize, for as they have been only conſidered as an ornamental tree, the frequent alterations which moſt of the gardens in England have undergone, have occaſioned their being rooted out wherever they were growing; but in ſome of the old gardens in Scotland, where they have been permitted to ſtand, there are large trees of this kind, which are fit to cut down for the uſe of the timber. I have ſeen two old trees of it in gardens, which were more than a yard in girt, at ſix feet from the ground, and theſe had been broken and abuſed, otherwiſe might have been much larger: they grow very faſt, and are extremely hardy, ſo may be well worth propagating upon poor ſhallow ſoils, and in expoſed ſituations. His Grace the Duke of Queenſberry ſowed a great quantity of the ſeeds of this tree, upon the ſide of the downs, at his ſeat near Ameſbury, in Wiltſhire, where the ſituation was very much expoſed, and the ſoil ſo ſhallow, as that few trees would grow there; yet in this place the young trees were twelve feet high in four years growth, ſo became a ſhelter to the other plantations, for which purpoſe they were deſigned; but the hares and rabbits are great enemies to theſe trees, by barking them in winter, ſo that where theſe trees are cultivated, they ſhould be fenced from theſe animals.

Both theſe ſorts are eaſily propagated by ſeeds, which the trees produce in great plenty. If theſe are ſown upon a common bed in March, the plants will appear by the middle or end of April, and will require no other care but to be kept clean from weeds during the following ſummer; and if the plants are too cloſe together, they may be tranſplanted the autumn following, either into a nurſery, where they may grow a year or two to get ſtrength, or into the places where they are deſigned to remain: where people would cultivate them for their wood, it will be the beſt way to ſow the ſeeds upon the ſpot where they are intended to grow, becauſe theſe trees ſend out long, thick, fleſhy roots to a great diſtance, which will penetrate gravel or rocks; and if theſe roots are cut or broken, it greatly retards their growth; therefore when they are not ſown upon the intended ſpot, they ſhould be tranſplanted thither young, otherwiſe they will not grow to near the ſize; though where they are only deſigned for ornament, the removing the plants twice will ſtop their growth, and cauſe them to be more productive of flowers; but all trees intended for timber, are much better ſown on the ground where they are deſigned to ſtand, than if they are tranſplanted.

If the ſeeds of theſe trees are permitted to ſcatter in winter, the plants will riſe in great plenty the following ſpring, ſo that a few trees will ſoon ſupply any perſon with a ſufficient number of the plants.

Theſe trees flower in May, at which time they make a fine appearance, their branches being generally loaded with long ſtrings of yellow flowers, which hang down from every part. The ſeeds grow in long pods, which ripen in autumn. There is a variety of both theſe trees with variegated leaves, which ſome perſons are fond of cultivating; but this is only to be done by cuttings or layers, for the ſeeds of theſe will produce plants with green leaves: the cuttings ſhould be planted in autumn, when the leaves begin to fall, and the plants muſt have a poor ſoil, for in good ground they are apt to become plain.

If the firſt ſort comes to be conſidered as a uſeful wood, which there is no reaſon to doubt it may be, it may be planted in large clumps in parks, where they will be very ornamental; and I am certain, from long experience, that this tree will thrive upon many ſoils, and in ſuch ſituations as few other trees will make any progreſs; the objection to fencing is the ſame here, as for any other trees, for wherever plantations are made, if they are not well ſecured from animals, they will not anſwer the deſign of the planters.

The ſecond ſort differs from the firſt, in having narrower leaves, longer bunches of flowers, and the trees do not grow ſo large and ſtrong; this difference I find is conſtant from ſeed. There is another ſort mentioned by Tournefort, with ſhorter bunches of flowers than either of theſe, one tree of which kind I thought I had found in a garden; the bunches of the flowers upon this tree were cloſe and almoſt round, but I ſowed the ſeeds of it, and the plants proved to be only the common ſort.

The third ſort grows naturally in Auſtria, in Italy and Spain, and at preſent is pretty rare in the Engliſh gardens; it was formerly in ſome of the curious gardens here, but had been long loſt, till a few years ago, when I procured the ſeeds from abroad, which ſucceeded in the Chelſea gardens, where the plants have flowered and produced ripe ſeeds, which have been communicated to ſeveral curious perſons.

This ſhrub ſeldom riſes more than three or four feet high in England; it naturally puts out many lateral branches near the ground, which ſpread out on every ſide, ſo as to form a low ſhrubby buſh, ſo is with difficulty raiſed to a ſtem: the branches are very ſlender, and their ends are frequently killed if the winter is ſevere; theſe are garniſhed with oblong oval leaves, growing by threes on each foot-ſtalk; they are equal in ſize, and of a dark green colour; the branches grow erect, and are terminated by ſpikes of yellow flowers, about four or five inches in length, ſtanding upright; and as all the branches are thus terminated, ſo when the ſhrubs are in flower, they make a fine appearance; it flowers in July, after moſt of the other ſorts are paſt, and the ſeeds ripen in autumn. This is propagated by ſeeds, which ſhould be ſown upon a bed of light earth in March, covering them about one third of an inch with fine ſcreened mould; in the beginning of May the plants will appear, when they muſt be carefully weeded, and during the following ſummer they muſt conſtantly be kept clean, which is all the culture they require till autumn, when it will be very proper to arch the bed over with hoops, that in froſty weather the plants may be covered with mats, to prevent their tender ſhoots from being killed; for as theſe young plants are apt to continue growing later in the autumn than thoſe which are become woody, ſo they are much more ſuſceptible of cold; therefore where there is not ſome care taken to cover them, if the winter ſhould prove ſevere, many of them may be entirely deſtroyed, and the others killed to the ground. The ſpring following, after the danger of hard froſt is over, the plants ſhould be carefully taken up, and planted out at the diſtance of one foot, row from row, and ſix inches aſunder in the rows; this ſhould be in a ſheltered ſituation, and as theſe plants do not ſhoot till late in the ſpring, ſo they need not be tranſplanted before the end of March, or the beginning of April; and if the ſeaſon ſhould then prove warm and dry, it will be proper to give the plants ſome water to ſettle the earth to their roots; and if the drought continue, and the waterings are three times repeated at a week's interval from each, it will be of ſervice to the plants. After they have taken new root, they will require no farther care, but to keep them conſtantly clean from weeds; in this nurſery the plants may remain two years, in which time they will have acquired ſtrength enough to be tranſplanted where they are to remain. There is a figure of this ſhrub exhibited in the 117th plate of my figures of plants.

The fourth ſort grows naturally in the ſouth of France, in Spain and Italy, but has been long cultivated in the nurſery gardens, as an ornamental flowering ſhrub, by the title of Cytiſus ſecundus Cluſii. This riſes with a woody ſtalk, putting out many branches which are covered with a browniſh bark, and garniſhed by obverſe, oval, ſmall leaves, growing by threes on very ſhort foot-ſtalks. The flowers are produced in cloſe ſhort ſpikes at the end of the branches, ſtanding erect; they are of a bright yellow colour, and appear in June; theſe are ſucceeded by ſhort broad pods, which contain one row of kidney-ſhaped ſeeds, which ripen in Auguſt. Theſe ſhrubs will riſe to the height of ſeven or eight feet, and become very buſhy; they are very hardy, ſo will thrive in any ſituation, and upon almoſt any ſoil, which is not too wet. They are propagated by ſeeds, which may be ſown upon a common bed of light earth in the ſpring, and kept clean from weeds the following ſummer; and in autumn the plants may be tranſplanted into a nurſery in rows, one foot apart, and at ſix inches diſtance in the rows, where they may remain two years to acquire ſtrength, and ſhould then be removed to the places where they are deſigned to grow.

The fifth ſort hath a ſoft ſhrubby ſtalk, dividing into many branches, which grow erect, and frequently riſe to the height of eight or ten feet; the ſtalks and leaves of this are very hairy; the leaves are oval, growing three upon each foot-ſtalk, and are placed cloſely on the branches; the flowers come out from the ſide of the ſtalk, in ſhort bunches; they are of a pale yellow, and appear in June; theſe are ſucceeded by long, narrow, hairy pods, with one row of kidney-ſhaped ſeeds, which ripen in September.

This ſort, of late years, has been much cultivated in the nurſery gardens near London, by the title of Evergreen Cytiſus of Naples; but as in ſevere froſt theſe ſhrubs are ſometimes killed, ſo they are not proper for every ſituation, therefore ſhould only be planted on a dry ſoil, and in warm ſituations; they are alſo very difficult to remove, when grown to any ſize, for they ſhoot long roots deep into the ground, and when theſe are broken or cut, the plants ſeldom ſurvive it. This may be propagated in the ſame manner as hath been directed for the third ſort. It grows naturally in the ſouth of France, in Spain and Italy.

The ſixth ſort hath herbaceous ſtalks, garniſhed with woolly leaves; the flowers are produced ſometimes ſingle, at other times two, three, or more grow together at the end of the branches; theſe appear in June, and are ſucceeded by hairy pods.

This plant is propagated by ſeeds, which may be ſown at the ſame time, and the plants ſhould be afterward treated in the ſame way, as is directed for the third ſort.

The ſeventh ſort grows naturally in Sicily, Italy, and Spain; this is a perennial plant, from whoſe downright root proceed ſeveral weak branches which trail upon the ground, and extend to the length of eight or ten inches; theſe are garniſhed with oblong leaves, placed by threes upon pretty long foot-ſtalks; they are hoary on their under ſide, but ſmooth above; the flowers are collected in heads at the end of the ſtalks, having a cluſter of leaves under them; they are of a deep yellow colour, and appear the latter end of June, and in warm ſeaſons theſe are ſucceeded by flat woolly pods, containing one row of ſmall kidney-ſhaped ſeeds, which ripen in September. This plant is propagated by ſeeds, which ſhould be ſown where the plants are to remain, and ſhould be treated in the ſame manner as the ſixth ſort.

The eighth ſort grows naturally in Tartary, from whence the eeds were ſent to the Imperial garden at Peterſburgh, and hath ſince been ſent to many of the curious gardens in Europe, which have been furniſhed with the ſeeds. This hath a ſhrubby ſtalk, which riſes near four feet high, dividing into many branches, which when young are covered with a green bark, cloſely garniſhed by oblong, oval, ſmooth leaves, which are of a hoary green colour; the flowers are produced in cloſe heads at the end of the branches, having a cluſter of leaves under them; they are of a bright yellow colour, and appear in the beginning of May; theſe are ſometimes ſucceeded by ſhort woolly pods, containing three or four ſmall kidney-ſhaped ſeeds in each. This is propagated by ſeeds, which ſhould be ſown early in April, on a border of ſtrong ground expoſed to the eaſt; for if they are ſown where they have full ſun, the plants will not thrive. This requires a cold ſituation and a pretty ſtrong ſoil, otherwiſe it will not thrive.

The ninth ſort grows naturally about Algiers, from whence the Rev. Dr. Shaw brought the ſeeds, which ſucceeded in the Chelſea garden. This riſes with a ſoft ſhrubby ſtalk to the height of eight or ten feet, putting out many ſlender branches on every ſide, garniſhed with ſmall wedge-ſhaped leaves, which are indented at the top, of a dark green colour and ſmooth; the flowers come out frequently ſingle from the ſide of the branches, theſe are large and of a bright yellow; they appear in June, and are ſometimes ſucceeded by pods containing three or four kidney-ſhaped ſeeds, which ripen in autumn. This ſort is too tender to live in the open air through the winter in England, therefore the plants muſt be treated in the ſame way as thoſe which are natives of the ſame country.

The tenth ſort grows naturally in the iſlands of the Archipelago; it riſes with a ligneous ſtalk ſix or ſeven feet high, ſending out many angular lateral branches, garniſhed with ſingle, narrow, ſpear-ſhaped leaves; the flowers are produced in ſhort bunches from the ſide of the branches; they are ſmall, yellow, and appear in July and Auguſt, but are not ſucceeded by ſeeds in England.

This is propagated by cuttings, which if planted on a bed of light earth the beginning of July, and are cloſely covered with a bell or hand-glaſs, which ſhould be ſhaded from the ſun in the middle of the day, they will put out roots by the middle or end of September; when they ſhould be carefully taken up, planting each in a ſeparate ſmall pot, carefully watering and ſhading them until they have taken new root; after which they may be expoſed in a ſheltered ſituation till the end of October, when they muſt be removed into ſhelter, for this plant is too tender to live in the open air in England.

The eleventh ſort grows naturally in the iſlands of America, and alſo at the Cape of Good Hope. This riſes with a weak ſhrubby ſtalk eight or ten feet high, ſending out many erect ſide branches, which grow erect, and are garniſhed with ſpear-ſhaped woolly leaves, placed by threes, the middle lobe having a longer diſtinct foot-ſtalk, than the two on each ſide which grow cloſe to the principal foot-ſtalk. The flowers come out from the ſide of the branches, ſometimes ſingle, at other times in cluſters; they are of a deep yellow colour, and about the ſize of thoſe of the common Laburnum; theſe are ſucceeded by hairy pods about three inches long, which are ſickle-ſhaped, ending with a long acute point, ſwelling at the place where each ſeed is lodged; the ſeeds are roundiſh, a little inclined to a kidney-ſhape. Theſe ſeeds are eſteemed an excellent food for pigeons in America, from whence it had the title of Pigeon Pea.

This plant grows only in very warm countries, ſo cannot be preſerved in England, unleſs it is placed in a warm ſtove. It riſes eaſily from ſeeds in a hot-bed, and will grow three or four feet high the firſt year, provided they have a proper heat, and the ſecond year they will produce flowers and ſeeds. The plants muſt be placed in the bark-bed in the ſtove, and treated in the ſame manner as other tender plants from the ſame countries: they ſhould have but little water in winter, and in the ſummer ſhould have a large ſhare of free air admitted to them in warm weather.

DALECHAMPIA. Lin. Gen. Plant. 1022. Plum. Nov. Gen. 17. tab. 38.

This plant was ſo named by father Plumier, in honour of the memory of Jacobus Dalechamp, who was a curious botaniſt.

The CHARACTERS are,

It hath male and female flowers on the ſame plant; the male flowers are ſituated between two bractea; they have a common involucrum cut into four erect ſegments; the empalement is compoſed of ſix obtuſe oval leaves, reflexed at their points. They have no petals, but have a broad nectarium, having many plain folds lying over each other, and many ſtamina joined in a long column, terminated by roundiſh ſummits having four furrows; the female flowers are alſo ſituated in the ſame manner as the male; theſe have a permanent three-leaved involucrum, and each have a permanent ten-leaved empalement; they have no petals, but a roundiſh germen ſhorter than the empalement, having three furrows ſupporting a long ſlender ſtyle, bending toward the male flowers, crowned by a beaded ſtigma; the germen afterward becomes a roundiſh capſule with three cells, incloſing one roundiſh ſeed in each.

This genus of plants is ranged in the ninth ſection of Linnæus's twenty-firſt claſs, intitled Monœcia Monadelphia, the plants having male and female flowers on the ſame root, and the ſtamina of the male flowers are joined in one body to the ſtyle.

We have but one SPECIES of this in England, viz.

DALECHAMPIA (*Scandens*) foliis trilobis glabris, floribus axillaribus caule volubili. *Dalechampia with ſmooth leaves having three lobes, flowers growing from the ſides of the branches, and a twining ſtalk.* Dalechampia ſcandens, lupuli foliis, fructu tricocco glabro, calyce hiſpido. Houſt. MSS.

This plant grows naturally in Jamaica, from whence the late Dr. Houſtoun ſent me the ſeeds, which ſucceeded in the Chelſea garden, where the plants have flowered and perfected their ſeeds. This muſt be a different plant from that which Plumier found growing in Martinico, or he has taken the involucrum for the ſeed-veſſel by his title of it; for he calls it fructu tricocco hiſpido, whereas this hath a ſmooth fruit with a hiſpid empalement.

It hath a root compoſed of many fibres, which extend to a great diſtance, from which ariſe ſeveral weak twining ſtalks, that faſten themſelves to the neighbouring plants, and mount up to a conſiderable height; theſe are garniſhed at each joint by one leaf, having three lobes; they are ſmooth, the two ſide lobes are oblique to the midrib, but the middle one is equal. The flowers are produced from the ſide of the ſtalks, three or four growing upon each footſtalk; ſome of theſe are male, and others female; they are of an herbaceous colour, and ſmall, ſo make no appearance; they have each a double involucrum, made up of two orders of leaves, which are narrow, and armed with ſmall briſtly hairs, which ſting the hands of thoſe who unwarily touch them; the flowers are ſucceeded by roundiſh capſules, having three prominent lobes which are ſmooth, each incloſing a ſingle ſeed.

This plant is propagated by ſeeds, which muſt be ſown early in the ſpring on a hot-bed; and when the plants are come up three inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall pot, filled with light rich earth, and then plunged into a hot-bed of tanners bark, being careful to ſcreen them from the ſun until they have taken new root; after which time the glaſſes of the hot-bed ſhould be raiſed every day, in proportion to the heat of the weather, to admit freſh air to the plants; they muſt alſo be frequently watered, for they naturally grow in moiſt places. When the plants have grown ſo large as to fill theſe pots with their roots, they ſhould be removed into larger pots, and placed in the bark-bed in the ſtove, where they muſt be ſupported either with ſtakes or a trellis, round which they will twine, and riſe to the height of eight or ten feet.

Theſe plants muſt be kept conſtantly in the ſtove, for they are too tender to bear the open air in this country, even in the ſummer ſeaſon; therefore they ſhould be placed with Convolvuluſes, and other twining plants, near the back of the ſtove, where ſhould be made an eſpalier to ſupport them; in which ſituation they will thrive, and produce their flowers, and ſometimes will perfect their ſeeds in this country; but, in order to this, they ſhould have a large ſhare of freſh air in warm weather, by drawing down the upper glaſſes of the ſtove; but in winter the ſtove ſhould be kept to a temperate heat, or rather higher. In ſummer they will require a large ſhare of water, but in winter it ſhould be given to them in leſs quantities, but muſt be frequently repeated. Theſe plants do not continue above two years, ſo that young plants ſhould be raiſed in order to preſerve the kind.

DAMASONIUM, Star-headed Water Plantain.

The CHARACTERS are,

It hath a flower compoſed of three leaves, which are placed orbicularly, and expand in form of a Roſe: out of the flower-cup riſes the pointal, which afterward becomes a ſtar-ſhaped fruit, with many cells, which are full of oblong ſeeds.

The SPECIES are,

1. DAMASONIUM (*Aliſma*) ſtellatum. Lugd. *Star-headed Water Plantain.*
2. DAMASONIUM (*Flava*) Americanum maximum, plantaginis folio, flore flaveſcente, fructu globoſo. Plum. *Greateſt American Water Plantain, with a Plantain leaf, a yellowiſh flower, and a globular fruit.*

The firſt of theſe plants is a native of England; it grows commonly in ſtanding waters, which are not very deep. It is ſometimes uſed in medicine, but never cultivated in gardens, ſo muſt be gathered for uſe in the places of its growth.

The ſecond ſort grows in Jamaica, Barbadoes, and ſeveral other places in the warm parts of America, where it is generally found in ſtagnating waters, and other ſwampy places; ſo that it would be difficult to preſerve this plant in England, for it will not live in the open air, and requires a bog to make it thrive; but as it is a plant of no great beauty or uſe, it is not worth the trouble of cultivating in this country.

DANDELION. See LEONTODON.

DAPHNE. Lin. Gen. Plant. 436. Thymelæa. Tourn. Inſt. R. H. 594. tab. 366. Spurge Laurel, or Mezereon.

The Characters are,

The flower hath no empalement; it is cylindrical, of one petal, which is cut into four parts at the top, where it ſpreads open; it hath eight ſhort ſtamina inſerted in the tube, which are alternately lower, terminated by erect bilocular ſummits. The oval germen is ſituated at the bottom of the tube, and is crowned by a headed depreſſed ſtigma; the germen afterward becomes a roundiſh berry with one cell, incloſing one roundiſh fleſhy ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's eighth claſs, intitled Octandria Monogynia, from the flower having eight ſtamina and one germen.

The Species are,

1. Daphne (*Laureola*) racemis axillaribus, foliis lanceolatis glabris. Lin. Sp. Plant. 357. *Daphne with bunches of flowers proceeding from the ſides of the branches, and ſmooth ſpear-ſhaped leaves.* Thymelæa lauri folio ſempervirens, ſeu laureola mas. Tourn. Inſt. 595. *Commonly called Spurge Laurel.*
2. Daphne (*Mezereon*) floribus ſeſſilibus ternis caulinis, foliis lanceolatis deciduis. Lin. Sp. Plant. 357. *Daphne with three flowers together ſitting cloſe to the ſtalk, and ſpear-ſhaped leaves, which fall off in autumn.* Thymelæa lauri folio deciduo, ſive laureola fœmina. Tourn. Inſt. 595. *Commonly called Mezereon.*
3. Daphne (*Thymelæa*) floribus ſeſſilibus axillaribus, foliis lanceolatis, caulibus ſimpliciſſimis. Lin. Sp. Plant. 356. *Daphne with flowers ſitting cloſe to the ſides of the branches, ſpear-ſhaped leaves, and ſingle ſtalks.* Thymelæa foliis polygalæ glabris. C. B. P. 463.
4. Daphne (*Tarton-raire*) floribus ſeſſilibus aggregatis axillaribus, foliis ovatis utrinque pubeſcentibus nervoſis. Lin. Sp. Plant. 356. *Daphne with flowers in cluſters ſitting cloſe to the ſides of the branches, and oval nervous leaves covered with ſilky hairs on both ſides.* Thymelæa foliis candicantibus ſerici inſtar mollibus. C. B. P. 463. *Commonly called Tarton-raire.*
5. Daphne (*Alpina*) floribus ſeſſilibus aggregatis lateralibus, foliis lanceolatis obtuſiuſculis ſubtus tomentoſis. Lin. Sp. Plant. 356. *Daphne with cluſters of flowers growing cloſe to the ſides of the branches, and ſpear-ſhaped blunt leaves woolly on their under ſide.* Chamelæa Alpina, folio infernè incano. C. B. P. 462.
6. Daphne (*Cneorum*) floribus congeſtis terminalibus ſeſſilibus, foliis lanceolatis nudis. Lin. Sp. Plant. 357. *Daphne with cluſters of flowers ſitting cloſe on the tops of the branches, and naked ſpear-ſhaped leaves.* Cneorum. Matth. Hiſt. 46.
7. Daphne (*Gnidium*) paniculâ terminali, foliis lineari-lanceolatis acuminatis. Lin. Sp. Plant. 357. *Daphne with a panicle of flowers terminating the branches, and narrow, ſpear-ſhaped, pointed leaves.* Thymelæa foliis lini. C. B. P. 463.
8. Daphne (*Squarroſa*) floribus terminalibus pedunculatis, foliis ſparſis linearibus patentibus mucronatis. Lin. Sp. Plant. 358. *Daphne with flowers terminating the branches, having foot-ſtalks, and narrow, ſpreading, acute-pointed leaves, placed ſcatteringly on the branches.* Thymelæa capitata lanuginoſa, foliis creberrimis minimis aculeatis. Burm. Afr. 134. tab. 49. fol 1.
9. Daphne (*Americana*) foliis linearibus acutis, floribus racemoſis axillaribus. *Daphne with very narrow acute leaves, and flowers growing in bunches from the ſides of the branches.* Thymelæa fruteſcens roriſmarini folio, flore albo. Plum. Cat.

The firſt ſort grows common in the woods in many parts of England, and is commonly known by the title of Spurge Laurel; of late years there are poor people, who get the young plants out of the woods, and carry them about the town to ſell in the winter and ſpring. This is a low evergreen ſhrub, which riſes with ſeveral ſtalks from the root to the height of two or three feet, dividing upward into ſeveral branches, garniſhed with thick ſpear-ſhaped leaves, which come out irregularly on every ſide, ſitting pretty cloſe to the branches, they are ſmooth and of a lucid green; between theſe, toward the upper part of the ſtalks, come out the flowers in ſmall cluſters; they are of a yellowiſh green, and appear ſoon after Chriſtmas, if the ſeaſon is not very ſevere; theſe are ſucceeded by oval berries, which are green till June, when they ripen and turn black, ſoon after which they fall off. The whole plant is of a hot cauſtic taſte, burning and inflaming the mouth and throat. The leaves continue green all the year, ſo theſe plants are ornamental in winter; and as they will thrive under tall trees, they are very proper to fill up the ſpaces in plantations.

The ſecond ſort grows naturally in Germany, and there hath been a diſcovery made of its growing in ſome woods near Andover in Hampſhire, from whence a great number of plants have been taken of late years. This has been long cultivated in the nurſery-gardens as a flowering ſhrub, and is a very ornamental plant in gardens, very early in the ſpring, before others make their appearance. There are two diſtinct ſorts of this, one with a white flower which is ſucceeded by yellow berries, the other with Peach-coloured flowers and red fruit. Theſe are by ſome ſuppoſed to be accidental varieties ariſing from the ſame ſeeds, but I have ſeveral times raiſed theſe plants from ſeeds, and always found the plants come up the ſame, as thoſe from which the ſeeds were taken, ſo they do not vary, therefore may be called different ſpecies. There is a variety of the Peach-coloured Mezereon, with flowers of a much deeper colour than the common, but theſe I have always found to vary in their colours when raiſed from ſeeds. This ſhrub grows to the height of five or ſix feet, with a ſtrong woody ſtalk, putting out many woody branches on every ſide, ſo as to form a regular head; the flowers come out very early in the ſpring, before the leaves appear, growing in cluſters all round the ſhoots of the former year; there are commonly three flowers produced from each knot or joint, ſtanding on the ſame ſhort foot-ſtalk; theſe have ſhort ſwelling tubes, which are divided into four parts at the top, which ſpread open; they have a very fragrant odour, ſo that where there are plenty of the ſhrubs growing together, they perfume the air to a conſiderable diſtance round them: after the flowers are paſt, the leaves come out, which are ſmooth, ſpear-ſhaped, and placed without order; they are about two inches long, and three quarters broad in the middle, gradually leſſening to both ends; the flowers are ſucceeded by oval berries, which ripen in June; thoſe of the Peach-coloured flowers are red, and thoſe of the white yellow. The flowers appear in February and March, and ſometimes in mild winters they appear in January. This plant was formerly uſed in medicine, but as every part of it has a hot cauſtic taſte, ſo few preſcribe the uſe of it at preſent.

This is propagated by ſeeds, which ſhould be ſown on a border expoſed to the eaſt, ſoon after the berries are ripe; for if they are not ſown till the ſpring following they often miſcarry, and always remain a year in the ground before the plants appear; whereas thoſe which are ſown in Auguſt, will grow the following ſpring, ſo that a year is ſaved, and theſe never fail. When the plants come up, they will require no other care but to keep them clean from weeds, and if the plants are not too cloſe together, they may continue in the ſeed-bed, to have the growth of two ſummers, eſpecially if they do not make great progreſs the firſt year; then at Michaelmas, when the leaves are ſhedding, they ſhould be carefully taken up ſo as not to break or tear their roots, and planted into a nurſery at about ſixteen inches row from row, and eight or nine inches aſunder in the rows; in this nurſery they may remain two years, by which time they will be fit to remove to the places where they are deſigned to remain for good: the beſt ſeaſon to tranſplant theſe trees is in autumn, for as theſe plants begin to vegetate very early in the ſpring, ſo it is not proper to tranſplant them at that ſeaſon. Theſe plants grow beſt in a light ſandy earth which is dry, for in cold wet land they become moſſy, and make little progreſs; ſo that upon ſuch ſoils they never grow to any ſize, and produce few flowers.

Although the berries of this tree are ſo very acrid, as to burn the mouth and throat of thoſe who may incautiouſly taſte them, yet the birds greedily devour them, as ſoon as they begin to ripen; ſo that unleſs the ſhrubs are covered with nets to preſerve the berries, they will all be deſtroyed before they are fit to gather. There is of this and the former ſort, ſome plants with variegated leaves, which ſome perſons are fond to have in their gardens, but the plain are much more beautiful.

The third ſort grows naturally in Spain, Italy, and the ſouth of France, where it riſes to the height of three or four feet, with a ſingle ſtalk covered with a light-coloured bark; the flowers come out in cluſters on the ſides of the ſtalks, which are of an herbaceous colour, ſo make but little appearance; they appear early in the ſpring, and are ſucceeded by ſmall berries which are yellowiſh when ripe.

The fourth ſort grows naturally in the ſouth of France, from whence I received the ſeeds. This is a low ſhrubby plant, which ſends out ſeveral weak ſtalks from the root, which grow about a foot long, and ſpread about irregularly; theſe ſeldom become woody in England, but are tough and ſtringy, covered with a light bark; the leaves are ſmall, of an oval form, and are very ſoft, white, and ſhining like ſattin; theſe ſit pretty cloſe to the ſtalks; between theſe the flowers come out in thick cluſters from the ſide of the ſtalks; they are white, and are ſucceeded by roundiſh berries having one hard ſeed. This flowers here in June, but doth not produce ripe ſeeds.

The fifth ſort grows on the mountains near Geneva, and in other parts of Italy, where it riſes about three feet high; the flowers of this come out in cluſters from the ſide of the branches, early in the ſpring. The leaves are ſpear-ſhaped, ending in blunt points, and are hoary on their under ſide. The flowers are ſucceeded by ſmall roundiſh berries, which turn red when ripe.

The ſixth ſort grows naturally on the Alps, as alſo upon the mountains near Verona, from whence it was ſent me; this is a very humble ſhrub, ſeldom growing more than one foot high, with ligneous ſtalks, which put out ſeveral ſide branches; theſe are garniſhed with narrow ſpear-ſhaped leaves, which are placed round the ſtalks without order; the branches are terminated by ſmall cluſters of purple flowers which ſtand erect, having no foot-ſtalks; the tubes of theſe flowers are longer and narrower than thoſe of the Mezereon, and the mouth is cut into four acute parts which are erect. Theſe flowers emit a pleaſant odour; they appear early in the ſpring, but do not produce ſeeds here.

The ſeventh ſort grows naturally about Montpelier; this riſes with a ſhrubby ſtalk about two feet high, dividing into many ſmall branches, which are cloſely garniſhed with narrow ſpear-ſhaped leaves growing erect, ending in acute points; the ends of the branches are terminated by panicles of flowers, which are much ſmaller than thoſe of the Mezereon, having ſwelling tubes, which are contracted at the mouth. Theſe appear in June, but are not ſucceeded by ſeeds here.

The eighth ſort grows naturally at the Cape of Good Hope; this ſhrub riſes to the height of five or ſix feet, dividing upward into ſeveral branches which grow erect, and are covered with a white bark, and cloſely garniſhed with ſmall narrow leaves, which come out on every ſide of the branches without order, ſpreading open; the tops of the branches are terminated by woolly heads, out of which the flowers come in ſmall cluſters; they are white, having oblong tubes, which are divided into four obtuſe ſegments at the mouth, which ſpread open. Theſe plants do not produce ſeeds in Europe.

The ninth ſort grows naturally in many iſlands in the Weſt-Indies, it was ſent me from Antigua. This ſhrub riſes to the height of four or five feet, with a woody ſtalk, covered with a rugged bark of an Aſh colour; the upper part of the branches are garniſhed with leaves about the ſize, and the ſame form as thoſe of Roſemary; between the leaves the flowers come out in ſmall bunches, upon foot-ſtalks an inch long; they have ſhort tubes cut into four parts at the top, and are white; theſe are ſucceeded by ſmall round berries, of a brown colour when they are ripe.

The third, fourth, and ſeventh ſorts are hardy, ſo will live through the winters in England in the open air, provided they are in a dry ſoil and a warm ſituation. The fifth and ſixth ſorts are as hardy as the common Mezereon, ſo are not in danger of being hurt by froſt in England; but they are all very difficult to keep in gardens, becauſe neither of them will bear to be tranſplanted. I have ſeveral times raiſed the plants from ſeeds, which have ſucceeded well in the places where they were ſown, but whenever they were removed, they certainly died, though performed at different ſeaſons, and with the greateſt care, and the ſame has happened to every other perſon who has raiſed any of theſe plants; and ſome of my correſpondents have aſſured me, they have frequently attempted to remove theſe plants from their natural places of growth, into their gardens, and have choſen plants of all ſizes, from the youngeſt ſeedlings to the oldeſt plants, yet have never ſucceeded in it; though they have uſed their utmoſt care, and have performed it at different ſeaſons. Therefore thoſe who are deſirous to have theſe plants in their gardens, muſt procure their ſeeds from the countries where they naturally grow; and when they arrive, they ſhould be immediately ſown where they are deſigned to remain, which for the third, fourth, and ſeventh ſorts, ſhould be on a very warm dry border, where, if there is a foundation of lime, rubbiſh, or chalk, under the upper ſurface of the ground, the plants will thrive better and continue much longer, than in better ground; and all the culture they require, is to keep the place clean from weeds, for the leſs the ground is ſtirred near their roots, the better the plants will thrive; for they naturally grow on poor ſhallow land, and out of crevices in rocks; ſo the nearer the ſoil approaches to this, the more likely the plants will be to ſucceed.

The fifth and ſixth ſorts may have a cooler ſituation; if theſe are ſown where they may have only the morning ſun, they will thrive better than in a warmer ſituation, and the ground near the roots of theſe ſhould not be diſturbed; therefore in the choice of the ſituation, there ſhould be regard had to this, not to ſow them near other plants, which may require tranſplanting, or to have the ground dug and looſened. The ſeeds of theſe plants coming from diſtant countries, rarely arrive here time enough to ſow in autumn, ſo that when they are ſown in the ſpring, the plants do not appear till the ſucceeding ſpring; and I have ſometimes had the ſeeds remain till the ſecond ſpring in the ground, before the plants have appeared; but as this may be too long for many people to leave the ground undiſturbed, ſo they had better put the ſeeds into ſmall pots of earth, and bury them in the ground the firſt ſummer, and in autumn take them up, and ſow them where they are to ſtand; by this method, the ſeeds will be forwarded to vegetate the following ſpring.

The fifth ſort is a beautiful ſweet ſhrub, ſo deſerves a place in gardens, as much as any of thoſe we cultivate for ornament. The firſt and ſecond ſorts are ſometimes uſed in medicine as was before obſerved, but being of a very cauſtic nature, are ſeldom preſcribed; but if proper trials were with caution made, it is not doubted but they may be found very efficacious in many ſtubborn diſorders, for ſome very ignorant quacks have performed great cures with theſe plants. The ſeventh ſort produces the Grana gnitida of the ſhops.

The eighth ſort grows naturally at the Cape of Good Hope, ſo will not live abroad in winter in England, but requires a good green-houſe to preſerve it. This plant is very difficult to keep or propagate in gardens.

The ninth ſort will not thrive in England, unleſs it is preſerved in the bark-ſtove; this plant will not bear tranſplanting, for I raiſed ſeveral from ſeeds which throve pretty well while they continued in the pot where they were ſown, but when they were tranſplanted, they all decayed.

DATISCA. Lin. Gen. Plant. 1003. Cannabina. Tourn. Cor. 52. Baſtard Hemp.

The Characters are,

It is male and female in different plants; the male flowers have an empalement compoſed of five narrow acute leaves; theſe have no petals, and ſcarce any viſible ſtamina, but have ten ſummits which are much longer than the empalement. The female flowers have no petals, but the empalements are the ſame as the male, having an oblong pervious germen, ſupporting three ſtyles, crowned by ſingle ſtigmas; the empalement afterward becomes an oblong triangular capſule, opening with three valves, having one cell filled with ſmall ſeeds, adhering to the three ſides of the capſule.

This genus of plants is ranged in the tenth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Dodecandria, from the male and female flowers growing in ſeparate plants, and the male flowers having ten ſtamina.

The Species are,

1. Datisca (*Cannabina*) caule lævi. Lin. Sp. Plant. 1037. *Datiſca with a ſmooth ſtalk.* Cannabina Cretica florifera & fructifera. Tourn. Cor. 52.
2. Datisca (*Hirta*) caule hirſuto. Lin. Sp. Plant. 1037. *Datiſca with a rough ſtalk.*

The firſt ſort grows naturally in Crete, and ſome other eaſtern countries. This hath a perennial root, from which ariſe ſeveral herbaceous ſtalks, about four feet high, garniſhed with winged leaves placed alternately, each being compoſed of three pair of lobes, terminated by an odd one; theſe are two inches long and half an inch broad, ending in acute points, and are deeply ſawed on their edges, of a light green. The flowers come out in long looſe ſpikes from the upper part of the ſtalks at the wings of the leaves, but having no petals, make but a poor appearance. The ſummits of the male flowers being pretty long, and of a bright yellow colour, are the only viſible parts of the flowers to be diſcerned at any diſtance.

The flowers on the female plants are ſucceeded by oblong three-cornered capſules, filled with ſmall ſeeds, which adhere to the three valves. The plants flower in June, and the ſeeds ripen in September. The ſtalks decay in autumn and new ariſe in ſpring.

This ſort may be propagated by parting the roots, which ſhould be performed in autumn when the ſtalks decay, (which is the beſt time to tranſplant the roots), but they muſt not be parted too ſmall; they may be planted in any open beds, where they are not under the drip of trees, and will require no other culture but to keep them clean from weeds.

It may alſo be propagated by ſeeds, but theſe ſhould be taken from ſuch plants as grew in the neighbourhood of male plants, otherwiſe they will not ſucceed; and if the ſeeds are not ſown in autumn, they ſeldom grow the firſt year. The ſeedling plants when they riſe, will require no other care but to keep them clean from weeds till autumn, when they may be tranſplanted where they are to grow.

The ſecond ſort grows naturally in Canada, and other parts of North America. This differs from the former, in having hairy ſtalks, which grow taller; the leaves are larger, and do not ſtand ſo near each other upon the ſtalks. It is equally hardy with the firſt ſort, and may be propagated in the ſame manner, but ſhould have a more ſhady ſituation and a moiſter ſoil.

DATURA. Lin. Gen. Plant. 218. Stramonium. Tourn. Inſt. R. H. 118. Thorn Apple.

The Characters are,

The flower is of one petal which is funnel-ſhaped, having a long cylindrical tube, ſpreading open at the top, which in ſome ſpecies is pentangular, each angle being pointed; the empalement of the flower is permanent, ſwelling in the middle, five-cornered, and tubulous; the flower hath five ſtamina, which are as long as the empalement, terminated by oblong compreſſed ſummits; it hath an oval germen, ſupporting an upright ſtyle, crowned by a thick obtuſe ſtigma. The germen afterward becomes an oval capſule, divided into four cells by a croſs intermediate partition, which are filled with kidney-ſhaped ſeeds adhering to the partition.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Datura (*Stramonium*) pericarpiis ſpinoſis erectis ovatis, foliis ovatis glabris. Hort. Cliff. 55. *Datura with an oval erect fruit having a prickly cover.* Stramonium fructu ſpinoſo rotundo, flore albo ſimplici. Tourn. Inſt. R. H. 118. *Thorn Apple with a round prickly fruit, and a ſingle white flower.*
2. Datura (*Tatula*) pericarpiis ſpinoſis erectis ovatis, foliis cordatis glabris dentatis. Lin. Sp. 256. *Datura with an erect oval fruit with a prickly cover, and ſmooth, heart-ſhaped, indented leaves.* Stramonium fructu ſpinoſo oblongo, flore violaceo. Tourn. Inſt. R. H. 119. *Thorn Apple with an oblong prickly fruit, and a Violet-coloured flower.*
3. Datura (*Metel*) pericarpiis ſpinoſis nutantibus globoſis, foliis cordatis ſubintegris pubeſcentibus. Hort. Cliff. 55. *Datura with a globular nodding fruit having a prickly cover, and heart-ſhaped, entire, hairy leaves.* Datura alba. Rump. 5. p. 242.
4. Datura (*Ferox*) pericarpiis ſpinoſis erectis ovatis, ſpinis ſupremis maximis convergentibus. Amœn. Acad. 3. p. 403. *Datura with an oval erect fruit, whoſe upper ſpines are largeſt, and converge together.* Stramomonium ferox. Bocc. 50. *Rough Thorn Apple.*
5. Datura (*Inoxia*) pericarpiis ſpinoſis inoxiis ovatis propendentibus, foliis cordatis pubeſcentibus. *Datura with an oval hanging fruit, whoſe cover is beſet with harmleſs ſpines, and heart-ſhaped hairy leaves.* Stramonium folio hyoſcyami, flore toto candido, fructu propendente rotundo, ſpinis inoxiis ornato. Boerh. Ind. alt. 1.
6. Datura (*Faſtuoſa*) pericarpiis tuberculoſis nutantibus globoſis, foliis lævibus. Lin. Sp. 256. *Datura with a globular nodding fruit, whoſe cover is ſet with tubercles and ſoft leaves.* Stramonium Ægyptiacum flore pleno, intus albo, foris violaceo. Tourn. Inſt. 119. *Egyptian Thorn Apple with a double flower, white on the inſide, and Violet-coloured on the outſide.*
7. Datura (*Arborea*) pericarpiis inermibus nutantibus, caule arboreo. Lin. Sp. Plant. 179. *Datura with a nodding fruit having an unarmed cover, and a tree-like ſtalk.* Stramonioides arboreum, oblongo & integro folio, fructu lævi, vulgò. Flori pondio. Feuil. tab. 46.

The firſt ſort here enumerated is the moſt common Thorn Apple in Europe, and was probably firſt introduced from Italy or Spain, where it naturally grows; but it is now become ſo common about London, and near other great towns in England, as to appear like a native plant; for there are few gardens or dunghills without this plant in ſummer, though it is only near ſuch places, where the plants may have been cultivated firſt in the gardens; and wherever any of theſe plants are permitted to ſeed, they will furniſh a ſupply of the plants for ſome years to come, as they produce a vaſt quantity of ſeeds, ſome of which will lie years in the ground, and when they are turned up to the air will vegetate.

This ſort ſeldom grows much more than two feet high, dividing into many ſtrong irregular branches which are hollow, garniſhed with large ſmooth leaves divided into irregular angles, and emit a fœtid odour. The flowers come out firſt from the forks or diviſions of the branches, and afterward near the extremities of the branches; they have long ſwelling tubes, which are dilated at the top into large pentagonal brims, each angle ending in a long point or ligula; theſe ſtand in long, green, five-cornered empalements, and are ſucceeded by large roundiſh ſeed-veſſels, covered with ſtrong thorns, divided by four furrows, to which adhere the partitions, which ſeparate the four cells, filled with black kidney-ſhaped ſeeds. It flowers in July, Auguſt, and September, and the ſeeds ripen in autumn, which, if permitted to ſcatter, will fill the ground about them with plants the following years. There was formerly a cooling ointment made with the leaves of this plant and hogs lard, which was greatly eſteemed for burns and ſcalds.

There is a variety (if not a diſtinct ſpecies of this) which grows naturally in North America; the plants of this grow more than twice the ſize of the former; the leaves are ſmoother, and of a lucid green, but the flowers and fruit are of the ſame form as thoſe of the other, ſo may be deemed a diſtinct ſpecies, eſpecially as the difference continues in the plants propagated in England.

The ſecond ſort grows naturally in moſt parts of America, for I have frequently received the ſeeds of it from the iſlands in the Weſt-Indies, and alſo from all the northern parts of America. This riſes with a purple ſtrong ſtalk to the height of four or five feet, dividing into many ſtrong branches, garniſhed with leaves ſhaped ſomewhat like thoſe of the former ſort, but larger, and have a greater number of angles and laciniæ on their edges; the flowers have longer and narrower tubes, and are of a purple colour; the fruit is alſo longer, and theſe differences are permanent. This is equally hardy with the former, and if the ſeeds are permitted to ſcatter, the plants will become troubleſome weeds. The third ſort hath a ſtrong ſtem, which riſes three feet high, and divides into many woolly branches; the leaves of this ſort are almoſt entire, having only two or three ſlight indentures on their edges; the flowers have long tubes, which extend beyond the bifid empalement, then they ſpread out very broad, where the brim is divided into ten obtuſe angles; they are of a pure white above, but the tubes have a tincture of green within. Theſe are ſucceeded by roundiſh fruit, cloſely covered with thorns, and are divided into four cells as the other, but the ſeeds of this are of a light brown colour when ripe.

This plant is not ſo hardy as the others, ſo the ſeeds muſt be ſown upon a gentle hot-bed in the ſpring, and the plants muſt be afterward treated in the ſame manner as the Marvel of Peru, and other of the hardier kinds of annual plants, and may be tranſplanted into the full ground the latter end of May. They will flower in July, and the ſeeds will ripen in autumn.

There is a variety of this with double flowers, but unleſs the plants of this are placed in a glaſs-caſe, they will not produce ſeeds in this country.

The fourth ſort is of humbler growth, ſeldom riſing more than a foot and a half high, ſpreading out into many branches, which are garniſhed with leaves ſomewhat like thoſe of the firſt ſort, but are ſmaller, and ſtand upon longer foot-ſtalks; the flowers are like thoſe of the firſt ſort, but ſmaller; the fruit is round, and armed with very ſtrong ſharp thorns, the upper being large, and converge toward each other. The ſeeds of this are black when ripe.

This ſort is too tender to be ſown in the full ground in England, ſo the plants ſhould be raiſed on a hot-bed, and afterward tranſplanted into borders as the former ſort.

The fifth ſort grows naturally at La Vera Cruz, from whence I received the ſeeds. This riſes with a purpliſh ſtem three or four feet high, dividing into ſeveral ſtrong branches, garniſhed with oblong heart-ſhaped leaves. The ſtalks, branches, and leaves of this ſort are covered with ſoft hairs; the flowers come out at the diviſion of the ſtalks and branches, ſtanding erect; they are large, white, and are ſucceeded by oval fruit, covered with long, ſoft, innocent ſpines, opening in four cells, which are full of brown ſeeds.

This plant is annual, and ſhould be firſt raiſed on a moderate hot-bed, then may be tranſplanted into open borders, where it will flower and perfect its ſeeds in the autumn. If theſe ſeeds are permitted to ſcatter, the plants will riſe the following ſpring, and if the ſummer proves warm, they will flower and often perfect their ſeeds.

The ſixth ſort grows naturally in Egypt, and alſo in India. This riſes with a fine poliſhed purple ſtalk four feet high, dividing into ſeveral branches, which are garniſhed with large, ſmooth, ſinuated leaves, ſtanding upon pretty long foot-ſtalks. The flowers are produced at the diviſions of the branches; theſe have large ſwelling tubes, which expand very broad at the top, their brims being divided into ten angles, each ending with a long ſlender point. The flowers are of a beautiful purple on their outſide, and a ſattiny white within; ſome of theſe are ſingle, others have two or three flowers ſtanding one within another, and ſome are double, having four or five petals within each other of equal length, ſo as to appear a full flower at the brim; they have an agreeable odour at firſt, but if long ſmelt to, become leſs agreeable, and are narcotic. If theſe plants are brought forward upon a hot-bed in the ſpring, and in June planted out on a warm border of rich earth, they will flower very finely in July and Auguſt; but unleſs they are covered with glaſſes, the ſeeds ſeldom ripen well in England. The fruit of this ſort is round, and grows nodding downward; the ſeed-veſſel is thick and fleſhy, as are alſo the intermediate partitions which divide the cells. The outſide of the fruit is covered with blunt protuberances, and the ſeeds are of a bright brown colour when ripe.

The ſeventh ſort was ſent me from La Vera Cruz by the late Dr. Houſtoun, who found it growing there naturally. This riſes with a woody ſtalk to the height of twelve or fourteen feet, dividing into ſeveral branches, which are garniſhed with oblique leaves ſix inches long, and two inches and a half broad in their broadeſt part, growing narrower at each end; they are oblique to the foot-ſtalk, which ſtands nearer to one ſide than the other; they are downy, and ſtand upon long foot-ſtalks. The flowers come out at the diviſion of the branches; theſe have a looſe tubular empalement near four inches long, which opens at the top on one ſide like a ſpatha or ſheath, within the empalement; the tube of the flower is narrow, but immediately above it ſwells very large for near ſix inches in length, then ſpreads open at the brim, where it is divided into five angles, which terminate in very long points; they are white, with ſome longitudinal ſtripes, of a pale yellow on their outſide; theſe are ſucceeded by round ſmooth capſules, filled with kidney-ſhaped ſeeds.

This tree is one of the greateſt ornaments to the gardens in Chili, where the inhabitants propagate it with great care. When the flowers are fully blown, they make a fine appearance, and a ſingle tree will perfume the air of a large garden.

This plant is tender, ſo requires to be kept in a ſtove in England. The ſeeds of this muſt be procured from the places where the trees naturally grow; they ſhould be perfectly ripe when gathered, and carefully put up, ſo as that the vermin cannot get to them, for they will deſtroy them. Moſt of the ſeeds which were ſent over by Dr. Houſtoun, were devoured in their paſſage by inſects, ſo that but few plants were raiſed. There were two or three of them raiſed in the gardens of the late Lord Petre, and two in the Chelſea garden; one of which came ſo far as to flower, but periſhed without producing ſeeds, ſo that at preſent I believe there is not any of the plants in England.

DAUCUS. Lin. Gen. Plant. 296. Tourn. Inſt. R. H. 307. tab. 161. [δαῦκος, which ſome derive of δαίω, *Gr.* to burn, of its ſharp and fiery power, or fervent taſte.] The Carrot.

The Characters are,

It hath an umbelliferous flower; the principal umbel is compoſed of a great number of ſmall ones called rays, which are ſhort, and in cluſters. The involucrum of the principal umbel is compoſed of many narrow leaves, having winged points; theſe are ſcarce ſo long as the umbel; thoſe of the rays are ſhorter and ſimple. The flowers have five heart-ſhaped petals which turn inward; thoſe which compoſe the rays are unequal in ſize, but thoſe of the diſk are nearly ſo; theſe have each five hairy ſtamina, terminated by roundiſh ſummits. The germen ſits under the flower, *ſupporting two reflexed ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes a ſmall, roundiſh, ſtriated fruit, dividing in two parts, each having a ſingle ſeed, convex and furrowed on one ſide, and plain on the other.*

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, the flower having five ſtamina and two ſtyles.

The Species are,

1. Daucus (*Sylveſtris*) ſeminibus hiſpidis, radice tenuiore fervido. *Carrot with a prickly ſeed, and a ſlender hot root.* Daucus vulgaris. Cluſ. Hiſt. 2. p. 198. *Common wild Carrot.*
2. Daucus (*Carota*) ſeminibus hiſpidis, radice carnoſo eſculento. *Carrot with a prickly ſeed, and a fleſhy eatable root.* Daucus ſativus, radice aurantii coloris. Tourn. Inſt. R. H. 307.
3. Daucus (*Gingidium*) radiis involucri planis, laciniis recurvis. Prod. Leyd. 97. *Carrot with plain rays to the involucrum, and recurved jags.* Daucus montanus lucidus. Tourn. Inſt. 307. *Shining maritime Carrot.*
4. Daucus (*Hiſpidus*) caule hiſpido, ſegmentis foliorum latioribus. *Carrot with a prickly ſtalk, and broader ſegments to the leaves.* Paſtinaca Oenanthes folio. Bocc. Rar. Pl. 75. *Parſnep with a Water Dropwort leaf.*
5. Daucus (*Creticus*) radiis involucri pinnatifidis, umbellis duplo longioribus, foliolis acutis. *Carrot with wing-pointed rays to the involucrum, which are twice the length of the umbel, and acute leaves.* Daucus tenuifolius Creticus, radiis umbellæ longioribus. Tourn. Inſt. R. H. 308. *Narrow-leaved Carrot of Crete, with rays longer than the umbel.*
6. Daucus (*Mauritanicus*) ſeminibus hiſpidis, floſculo centrali ſterili carnoſo, receptaculo communi hemiſphærico. Lin. Sp. 348. *Carrot with hiſpid ſeeds, the central flower barren, and the common receptacle hemiſpherical.* Daucus Hiſpanicus, umbella magna. Tourn. Inſt. 308.
7. Daucus (*Viſnaga*) ſeminibus nudis. Hort. Cliff. 89. *Carrot having naked ſeeds.* Gingidium umbella oblongâ. C. B. P. 151. *Gingidium with an oblong umbel.*
8. Daucus (*Muricatus*) ſeminibus aculeatus. Lin. Sp. 349. *Carrot with prickly ſeeds.* Caucalis major Daucoides Tingitana. Mor. Hiſt. 3. p. 308.

The firſt ſort is the common wild Carrot, which grows by the ſide of fields, and in paſture grounds in many parts of England. The plants of this ſort do not differ greatly in appearance from the Garden Carrot, which has led ſome perſons into an opinion of their being the ſame plant; but thoſe who have attempted to cultivate the wild ſort, are fully convinced of their being diſtinct plants. I have tried to cultivate the wild ſort for many years, but could never get the ſeeds which were ſown in the ſpring to grow, upon which I ſowed the ſeeds in autumn, part of which have come up well; theſe plants I cultivated in the ſame manner as the Garden Carrot, but could not improve the roots in the leaſt, for they continued to be ſmall, ſticky, and of a hot biting taſte; and this has been always the caſe, wherever the plants have been ſown, therefore there can be no doubt of their being different plants. The ſeeds of this ſort are uſed in medicine, and are eſteemed good to bring away gravel; it is an excellent diuretic, but inſtead of theſe ſeeds, the ſhops are uſually ſupplied with old ſeeds of the Garden Carrot, when they have loſt their vegetative quality, then the ſeedſmen ſell them to the druggiſts for medicinal uſe; but certainly all ſeeds which are too old to grow, can have little virtue remaining in them.

There are ſeveral varieties of the Garden Carrots, which differ in the colour of their roots, and theſe variations may be continued, where there is proper care taken not to mix the different ſorts together in the ſame garden; but the Orange Carrot is generally eſteemed in London, where the yellow and the white Carrots are ſeldom cultivated.

The dark red, or purple Carrot, I take to be a diſtinct ſort from either of theſe; but as it is much tenderer, I have not had an opportunity of ſeeing it in the flower, for the roots were all deſtroyed by the firſt froſts in autumn. The ſeeds of this ſort were ſent me from Aleppo, which ſucceeded very well; the roots were not ſo large as thoſe of the other ſorts of Carrots, and were of a purple colour, very like that of a deep-coloured Radiſh; they were very tender and ſweet; the leaves were finer cut than thoſe of the common Carrot, and were leſs hairy.

The ſecond ſort is commonly cultivated in gardens for the kitchen, and the different varieties of it are, in ſome places, eſteemed, though in London, the Orange Carrot is preferred to all the other.

They are propagated at two or three different ſeaſons, or ſometimes oftener, where people are fond of young Carrots, whenever they can be procured. The firſt ſeaſon for ſowing the ſeeds is ſoon after Chriſtmas, if the weather is open, which ſhould be in warm borders, near walls, pales, or hedges, but they ſhould not be ſown immediately cloſe thereto; but a border of Lettuce, or other young ſallad herbs, of about a foot wide, ſhould be next the wall, &c. for if the Carrots were ſown cloſe to the wall, they would draw up weak, without making any tolerable roots.

Theſe delight in a warm ſandy ſoil which is light, and ſhould be dug pretty deep, that the roots may the better run down; for if they meet with any obſtruction, they are very apt to grow forked, and ſhoot out lateral roots, eſpecially where the ground is too much dunged the ſame year that the ſeeds are ſown, which will alſo occaſion their being worm-eaten; it is therefore the better method to dung the ground intended for Carrots the year before they are ſown, that it may be conſumed, and mixed with the earth; but in ſuch places where there has not been ground ſo prepared the year before, and there may be a neceſſity for dunging it the ſame year as the Carrots are ſown, the dung ſhould be well rotted which is laid upon it, and ſhould be thinly ſpread over the ground; and in the digging of it into the ground, great care ſhould be taken to diſperſe it all through the ground, and not to bury it in heaps, for that will ſtop the roots of the Carrots in their downright growth, and cauſe them to be ſhort and forky. Where the ground is inclinable to bind, there cannot be too much care taken to break and divide the parts; therefore in digging the land for Carrots, there ſhould never be large ſpits taken, but they muſt be very thin, and the clods well broken; which, if not attended to by the maſter, is ſeldom properly performed by workmen, who are too apt to hurry over their work, if they are not well obſerved.

The ground when dug ſhould be laid level and even, otherwiſe when the ſeeds are ſown and the ground is raked over, part of the ſeeds will be buried too deep, and others will be in danger of being drawn up into heaps; ſo the plants will come up in bunches, and other parts of the ground be naked, which ſhould always be carefully avoided.

The ſeeds have a great quantity of ſmall forked hairs upon their borders, by which they cloſely adhere, ſo that they are difficult to ſow even, ſo as not to come up in patches; you ſhould therefore rub it well through both hands, whereby the ſeed will be ſeparated before it is ſown; then you ſhould chooſe a calm day to ſow it in, for if the wind blows, it will be impoſſible to ſow it equal, for the ſeeds being very light, will be blown into heaps. When the ſeed is ſown, you ſhould tread the ground pretty cloſe with your feet, that it may be buried, and then rake the ground level.

When the plants are come up and have got four leaves, you ſhould hoe the ground with a ſmall hoe about three inches wide, cutting down all young weeds, and ſeparating the plants to four inches diſtance each way, that they may get ſtrength; and in about a month or five weeks after, when the weeds begin to grow again, you ſhould hoe the ground over a ſecond time, in which you ſhould be careful not to leave two Carrots cloſe to each other, as alſo to ſeparate them to a greater diſtance, cutting down all weeds, and ſlightly ſtirring the ſurface of the ground in every place, the better to prevent young weeds from ſpringing, as alſo to facilitate the growth of the young Carrots.

In about a month or five weeks after, you muſt hoe them a third time, when you muſt clear the weeds as before; and now you ſhould cut out the Carrots to the diſtance they are to remain, which muſt be proportioned to the ſize you intend to have them grow. If they are to be drawn while young, five or ſix inches aſunder will be ſufficient, but if they are to grow large before they are pulled up, they ſhould be left eight or ten inches diſtant every way; you muſt alſo keep them clear from weeds, which, if ſuffered to grow amongſt the Carrots, will greatly prejudice them.

The ſecond ſeaſon for ſowing theſe ſeeds is in February, on warm banks, ſituated near the ſhelter of a wall, pale, or hedge; but thoſe which are intended for the open large quarters, ſhould not be ſown before the beginning of March, nor ſhould you ſow any later than the end of the ſame month; for thoſe which are ſown in April or May, will run up to ſeed before their roots have any bulk, eſpecially if the weather ſhould prove hot and dry.

In July you may ſow again for an autumnal crop, and at the end of Auguſt you may ſow ſome to ſtand the winter; by which method you will have early Carrots in March, before the ſpring ſowing will be fit to draw; but theſe are ſeldom ſo well taſted, and are often very tough and ſticky. However, as young Carrots are generally expected early in the ſpring, moſt people ſow ſome at this ſeaſon; but theſe ſhould be ſown upon warm borders and dry land, otherwiſe they are ſeldom good. If the winter ſhould prove very ſevere, it will be proper to cover the young Carrots with Peaſe-haulm, the haulm of Aſparagus, or ſome ſuch light covering, to prevent the froſt from penetrating into the ground, which often deſtroys the Carrots, where this care is wanting: but if in very hard winters the Carrots ſhould be all deſtroyed which were ſown in autumn, there ſhould be a hot-bed made early in the ſpring to ſow ſome, which will be fit for uſe long before any that are ſown in the full ground; but theſe beds ſhould be earthed fifteen or ſixteen inches deep, that the roots may have a proper depth of ſoil to run down. If theſe beds are lined with hot dung twice, at ſuch times when the heat of the beds decline, it will greatly forward the growth of the Carrots, but there ſhould be great care taken not to draw the plants up too weak; theſe may be allowed to grow cloſer together than thoſe ſown in the full ground, becauſe they will be drawn for uſe very young. Many people mix ſeveral other ſorts of ſeeds, as Leek, Onion, Parſnep, Radiſh, &c. amongſt their Carrots; and others plant Beans, &c. but, in my opinion, neither of theſe methods are good; for, if there is a full crop of any one of theſe plants, there can be no room for any thing elſe amongſt them, ſo that what is got by one is loſt by another; and beſides, it is not only more ſightly, but better, for the plants of each kind to be ſown ſeparate; and alſo by this means your ground will be clear, when the crop is gone, to ſow or plant any thing elſe; but when three or four kinds are mixed together, the ground is ſeldom at liberty before the ſucceeding ſpring: beſides, where Beans, or any other tall-growing plants are planted amongſt the Carrots, they are apt to make them grow more in top than root; ſo that they will not be half ſo large as if ſown ſingly, without any other plants amongſt them.

The covetouſneſs of ſome gardeners will not permit them to cut out their Carrots to a proper diſtance when they hoe them, ſo that by leaving them cloſe, they draw each other up weak: and if they are drawn while young, they never recover their ſtrength afterward ſo perfectly, as to grow near the ſize of thoſe which are properly thinned at the firſt hoeing; therefore where the Carrots are deſigned to have large roots, they muſt never ſtand too cloſe, nor ſhould they have any other crop mixed with them.

This root has been long cultivated in gardens for the table, but has not till of late years been cultivated in the fields for cattle, nor has it been practiſed as yet but in few parts of England; it is therefore greatly to be wiſhed, that the culture of it was extended to every part of England, where the ſoil is proper for the purpoſe; for there is ſcarce any root yet known, which more deſerves it, being a very hearty good food for moſt ſorts of animals. One acre of Carrots, if well planted, will fatten a greater number of ſheep or bullocks, than three acres of Turneps, and the fleſh of theſe animals will be firmer and better taſted. Horſes are extremely fond of theſe roots, and for hogs there is not any better food. I have alſo known theſe roots cultivated for feeding of deer in parks, which has proved of excellent uſe in hard winters, when there has been a ſcarcity of other food; at which times great numbers of deer have periſhed for want, and thoſe which have eſcaped, have been ſo much reduced, as not to recover their fleſh the following ſummer; whereas, thoſe fed with Carrots have been kept in good condition all the winter, and upon the growth of the graſs in the ſpring, have been fat early in the ſeaſon, which is an advantage, where the graſs is generally backward in its growth.

There is alſo an advantage in the cultivation of this root beyond that of the Turnep, becauſe the crop is not ſo liable to fail; for as the Carrots are ſown in the ſpring, the plants generally come up well, and unleſs the months of June and July prove very bad, there is no danger of the crop ſucceeding; whereas Turneps are frequently deſtroyed by the flies at their firſt coming up, and in dry autumns they are attacked by caterpillars, which in a ſhort time devour whole fields, but Carrots are not attacked by theſe vermin: therefore every farmer who has a ſtock of cattle or ſheep, ſhould always have a ſupply of theſe roots, if he has land proper for the purpoſe, which muſt be light, and of a proper depth to admit of the roots running down.

In preparing the land for Carrots, if it has not been in tillage before, it ſhould be ploughed early in autumn, and then ploughed acroſs again before winter, laying it up in high ridges to mellow by the froſt; and if the ground is poor, there ſhould be ſome rotten dung ſpread over it in winter, which ſhould be ploughed in about the beginning of February; then in March, the ground ſhould be ploughed again to receive the ſeeds; in the doing of which, ſome farmers have two ploughs, one following the other in the ſame furrow, ſo that the ground is looſened a foot and a half deep. Others have men with ſpades following the plough in the furrows, turning up a ſpit of earth from the bottom, which they lay upon the top, levelling it ſmooth and breaking the clods; the latter method is attended with a little more expence, but is much to be preferred to the firſt, becauſe in this way the clods are more broken, and the ſurface of the ground is laid much evener.

If the land has been in tillage before, it will require but three ploughings; the firſt juſt before winter, when it ſhould be laid in high ridges for the reaſons before given; the ſecond croſs ploughing ſhould be in February, after which, if it is well harrowed to break the clods, it will be of great ſervice; the laſt time muſt be in March to receive the ſeeds, this ſhould be performed in the manner before mentioned. After this third ploughing, if there remain great clods of earth unbroken, it will be proper to harrow it well before the ſeeds are ſown. One pound and a half of ſeeds will be ſufficient for an acre of land, but as they are apt to adhere together, it renders them more difficult to ſow even than moſt other ſorts; therefore ſome mix a quantity of dry ſand with their ſeeds, rubbing them well together, ſo as to ſeparate the Carrot ſeeds from each other, which is a good method. After the ſeeds are ſown, they muſt be gently harrowed in to bury them; and when the plants come up, they ſhould be hoed in the manner before directed.

But in order to preſerve your Carrots for uſe all the winter and ſpring, you ſhould, about the beginning of November, when the green leaves are decayed, dig them up, and lay them in ſand in a dry place, where the froſt cannot come to them, taking them out from time to time as you have occaſion for them, reſerving ſome of the longeſt and ſtraiteſt roots for ſeed, if you intend to ſave any; which roots ſhould be planted in the middle of February, in a light ſoil, about a foot aſunder each way, obſerving to keep the ground clear from weeds; and about the middle of Auguſt, when you find the ſeeds are ripe, you muſt cut it off, and carry it to a dry place, where it ſhould be expoſed to the ſun and air for ſeveral days to dry; then you may beat out the ſeeds, and put it up in bags, keeping it in a dry place until you uſe it. This ſeed is ſeldom eſteemed very good after the firſt or ſecond year at moſt, but new ſeed is always preferred, nor will it grow when it is more than two years old.

The third ſort grows naturally about Montpelier; this hath ſmoother ſtalks than the common Carrot, the ſegments of the leaves are broader, and of a lucid green; the umbels of the flowers are larger, and not ſo regular. This is an annual plant, but it ſucceeds beſt when ſown in autumn.

The fourth ſort is of lower growth than either of the former; the ſtalks are cloſely covered with ſhort prickles, the ſegments of the leaves are broad and obtuſe, the umbels are ſmall, and the involucrum is longer than the umbel, and the leaves are trifid which compoſe it.

The fifth ſort riſes with a ſlender, rough, hairy ſtalk upward of two feet high; the leaves are ſhort, and have a few ſmall ones intermixed, which are thinly placed, and cut into acute ſegments; the umbels are not ſo large as thoſe of the common ſort, and the involucrum is twice the length of the umbel; the leaves which compoſe it are divided into five or ſeven parts, ending in acute points; the flowers are yellow.

The ſixth ſort hath a channelled ſtalk riſing near three feet, which is terminated by large umbels of flowers, with a wing-pointed involucrum; the ſegments of the lower leaves are cut into obtuſe ſegments, and are of a deep green colour.

The ſeventh ſort is an annual plant, which grows naturally in Spain and Italy; this riſes with an upright, ſmooth, channelled ſtalk three feet high, garniſhed with ſmooth leaves, which are divided into many fine narrow ſegments like thoſe of Fennel; the ſtalks branch out upward, and each branch is terminated by a large umbel, compoſed of a great number of ſmall ones; the involucrum is ſhorter than the umbel, and each of the leaves which compoſe it is trifid: the foot-ſtalks which ſuſtain the ſmall umbels (or rays) are long and ſtiff; theſe are by the Spaniards uſed for picking their teeth, from whence the plant had the title of Viſnaga, or Pick-tooth. The ſeeds of this plant ſhould be ſown in autumn, for thoſe which are ſown in the ſpring frequently fail, or at leaſt remain in the ground till next year before they grow; the plants require no other culture but to keep them clean from weeds, and thin them where they are too cloſe.

The eighth ſort grows naturally about Tangier. This riſes with an upright ſtalk above two feet high, garniſhed with double-winged leaves which are hairy; the ſtalk branches upward into ſeveral diviſions, each being terminated by an umbel of white flowers, which are ſucceeded by prickly ſeeds.

If the ſeeds of this ſort are not ſown in the autumn, the plants rarely perfect their ſeeds in this country; for when they are ſown in the ſpring, and the plants come up ſoon after, they generally run up to ſeed in autumn, ſo that the froſts come on before they have time to ripen.

Theſe ſorts are ſometimes preſerved in botanic gardens for the ſake of variety, but being of no uſe, are not cultivated in other gardens.

DAUCUS CRETICUS. See ATHAMANTA.

D'AYENIA, Monier.

This genus of plants receives its title from Monſeigneur Le Duc D'Ayen, who is a great lover and promoter of the ſcience of botany; and has a noble garden at St. Germains, which is well ſtored with rare plants from many different parts of the world, and has appointed Dr. Monier, member of the Royal Academy of Sciences, the ſuperintendent of it.

The CHARACTERS are;

It hath an empalement compoſed of five ſmall oval leaves which are dry. The flower hath five petals, whoſe points are united to a plain ſtarry nectarium; the nectarium ſits upon a cylindrical column which is erect, and the length of the empalement; it is bell-ſhaped, having five depreſſed lobes at the margin: it hath five ſhort ſtamina inſerted into the border of the nectarium, terminated by roundiſh ſummits, which are joined to the border of the petals. It hath a roundiſh germen in the bottom of the nectarium, ſupporting a cylindrical ſtyle, crowned by a five-cornered obtuſe ſtigma. The capſule hath five cells, incloſing five oblong ſeeds faſtened to the capſule.

This genus of plants is ranged in the fourth ſection of Linnæus's twentieth claſs, intitled Gynandria Pentandria, the flowers having five ſtamina, which are faſtened with the ſtyle to the nectarium.

We at preſent know but one SPECIES of this genus, viz.

D'AYENIA (*Puſilla*) foliis cordatis glabris. Lin. Sp. 1354. *D'Ayenia with heart-ſhaped ſmooth leaves.*

The ſeeds of this plant were ſent by the younger De Juſſieu from Peru to Paris, where they ſucceeded, and have ſince been communicated to many other gardens in Europe. I received the ſeeds from Dr. Monier, intendent of the garden of the Duke D'Ayen at St. Germains, which have for ſome years grown in the Chelſea garden, where the plants annually flower and perfect their ſeeds.

This plant hath a weak ligneous ſtalk, which divides into ſeveral ſlender branches, riſing from nine inches to a foot high, garniſhed by heart-ſhaped ſmooth leaves, which are ſlightly indented on their edges, ſtanding upon pretty long foot-ſtalks; they are of a lucid green, and end in acute points, placed alternately on the branches. At the baſe of each foot-ſtalk, from the ſide of the branches, come out the flowers, two, three, or four, ariſing from the ſame point, each ſtanding upon a ſeparate ſlender foot-ſtalk; they have five ſlender ſtamina, collected into a ſort of column, like the malvaceous flowers, having a five-cornered germen at the bottom, which afterward becomes a roundiſh five-cornered capſule, having five cells, in each of theſe is lodged one kidney-ſhaped ſeed. The flowers are tubulous, ſpreading open at the top, where they are cut into five acute ſegments, each being terminated by a ſlender tail; they are purple, and continue in ſucceſſion on the ſame plants from July to the winter.

This plant is propagated by ſeeds, which ſhould be ſown upon a moderate hot-bed early in the ſpring; and when the plants are come up, and have four leaves, they ſhould be tranſplanted on a freſh hot-bed to bring them forward; part of them may be planted in ſmall pots, and the others may be planted on the bed: thoſe in the pots ſhould be plunged into a hot-bed of tanners bark; they muſt be ſhaded till they have taken new root, then they muſt have free air admitted to them every day, in proportion to the warmth of the ſeaſon; they require to be frequently watered in warm weather, but they ſhould not have it in too great plenty. The plants ſhould continue all the ſummer in the hot-bed, where they muſt have a good ſhare of air; for thoſe which are fully expoſed to the open air will not thrive, and if they are too much drawn, they do not flower well. The plants will live through the winter in a moderate ſtove; but as they perfect their ſeeds well the firſt year, few perſons care to continue the old plants. There is a figure of this plant exhibited in the 118th plate of our figures of plants.

DAY-LILY. See HEMEROCALLIS.

DECORTICATION, is the pulling off the outward bark of trees, alſo the peeling or barking of roots.

DELPHINIUM. Lin. Gen. Plant. 602. Tourn. Inſt. R. H. 426. tab. 241. [Δελφὶν, *Gr.* a dolphin; ſo called, becauſe the flower, before it opens, reſembles a dolphin. It is called Conſolida Regalis, from its conſolidating virtue. Caſpar Bauhin calls it the Royal Plant, becauſe it has its cup turned backwards, like a nobleman's badge. Cæſalpinus, Pliny, and the poets ſay, this plant is the true Hyacinth, becauſe it has the ſyllable ai inſcribed on its flower, which is a particle of bewailing,] Larkſpur, or Larkſheel.

The Characters are,

The flower hath no empalement; it is compoſed of five unequal petals placed circularly; the upper petal is extended at the hinder part into a tubular obtuſe tail; the two ſide petals are nearly of the ſame ſize with the upper, but the two lower are ſmaller; theſe ſpread open. There is a bifid nectarium ſituated in the center of the petals, and is involved in the tube by the back part. The flower hath many ſmall ſtamina which incline to the petals, and are terminated by ſmall erect ſummits; it hath three oval germen, ſupporting three ſtyles which are as long as the ſtamina, crowned by reflexed ſtigmas; the germen afterward become ſo many capſules joined together, which open croſſways, each having one cell filled with angular ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's thirteenth claſs, intitled Polyandria Trigynia, the flower having many ſtamina and three ſtyles

The Species are,

1. Delphinium (*Conſolida*) nectariis monophyllis, caule ſubdiviſo. Hort. Cliff. 217. *Larkſpur with a one-leaved nectarium and a divided ſtalk.* Delphinium ſegetum. Tourn. Inſt. 426. *Corn Larkſpur, and the* Conſolida regalis arvenſis. C. B. P. 142. *Field Royal Conſound.*
2. Delphinium (*Ajacia*) nectariis monophyllis, caule ſimplici. *Larkſpur with a one-leaved nectarium, and an erect ſtalk.* Delphinium hortenſe, flore majore & ſimplici cæruleo. Tourn. Inſt. R. H. 426. *Garden Larkſpur, with a larger ſingle blue flower.*
3. Delphinium (*Ambiguum*) nectariis monophyllis, caule ramoſo. *Larkſpur with a one-leaved nectarium and a branching ſtalk.* Delphinium elatius purpuro violaceum. Suvert. Flor. *Branched Larkſpur.*
4. Delphinium (*Peregrinum*) nectariis diphyllis corollis enneapetalis capſulis teretis, foliis multipartitis obtuſis. Hort. Cliff. 213. *Larkſpur with a two-leaved nectarium, a flower with eleven petals and three capſules, and leaves divided into many obtuſe ſegments.* Delphinum latifolium, parvo flore. Tourn. Inſt. R. H. 426. *Broad-leaved Larkſpur with a ſmall flower.*
5. Delphinium (*Elatum*) nectariis diphyllis, labellis bifidis, apice barbatis, foliis inciſis, caule erecto. Hort. Upſal. 151. *Larkſpur with a two-leaved nectarium, a bifid lip bearded at the top, cut leaves, and an erect ſtalk.* Delphinium perenne montanum villoſum, aconiti folio. Tourn. Inſt. 426. *Perennial hairy Mountain Larkſpur with a Monkſhood leaf, commonly called the Bee Larkſpur.*
6. Delphinium (*Grandiflorum*) nectaris diphyllis, labellis integris, floribus ſubſolitariis, foliis compoſitis lineari-multipartitis. Hort. Upſal. 150. *Larkſpur with a two-leaved nectarium, an entire lip, flowers growing ſingly, and compound leaves divided into many narrow parts.* Delphinium humilius anguſtifolium perenne, flore azureo. Amman. *Dwarf narrow-leaved perennial Larkſpur with an azure flower.*
7. Delphinium (*Americanum*) nectariis diphyllis, labellis integris, floribus ſpicatis, foliis palmatis multifidis glabris. Plate 119. *Larkſpur with a two-leaved nectarium, an entire lip, flowers growing in ſpikes, and palmated, multifid, ſmooth leaves, commonly called American Larkſpur.*
8. Delphinium (*Staphiſagria*) nectariis diphyllis, foliis palmatis, lobis integris. Hort. Cliff. 213. *Larkſpur with a two-leaved empalement, and palmated leaves having entire lobes.* Delphinium platani folio, ſtaphyſagria dictum. Tourn. Inſt. R. H. 428. *Larkſpur with a Plane-tree leaf, called Staveſacre.*

The ſeveral varieties of the Garden Larkſpur are not here enumerated, as they would ſwell the work beyond its intended bulk, if all theſe were diſtinguiſhed, therefore here are only the diſtinct ſpecies mentioned; and as the gardeners diſtinguiſh the Garden Larkſpurs into thoſe which are branched, and ſuch as have upright ſtalks; which difference is permanent, and never alters, whatever may be aſſerted to the contrary by ignorant pretenders; ſo I ſhall juſt mention the ſeveral varieties which there are of each ſort, commonly cultivated in the gardens of the curious. And firſt of the branched Larkſpur, there are of the following colours, with ſingle and double flowers.

Blue, purple, white, fleſh, Aſh, and Roſe colours; and ſome have flowers beautifully ſpotted, with two or three of theſe different colours.

The upright or unbranched Larkſpur, produces a greater variety of colours than the branched, and the flowers are larger and fuller than thoſe; but the principal colours run nearly the ſame with thoſe of the other, though many of the colours are deeper, and there are more different ſhades of theſe colours in the flowers of this ſort.

The firſt ſort grows naturally on arable lands, in France, Spain, and Italy, and is ſuppoſed to be the ſame as the Garden Larkſpur, which is a great miſtake; for I have cultivated it many years in the garden, and never found it alter: the leaves of this ſort are broader, and not ſo much divided as thoſe of the garden kind, and are placed thinner upon the ſtalks; the flowers are ſmaller, and grow in longer ſpikes; the ſtalks are not ſo much branched as that ſort which is called the branched, nor are they ſingle like the upright, ſo that I think it may be allowed to be a different ſpecies.

The ſecond ſort hath upright ſtalks, which ſcarce put out any branches; the ſpikes of flowers grow erect, and the flowers are placed very cloſe together, ſo that they make a fine appearance. Theſe plants flower in July and Auguſt, and are very great ornaments to the borders of the flower-garden.

The branching Larkſpur, which is the third ſort, comes later to flower than the upright; this riſes with a very branching ſtalk three feet high or more; the branches come out horizontally from the ſide of the ſtalks, but afterward turn that part on which the ſpike of flowers grow, which is at the extremity upward, ſo as to make an angle; the leaves are long and finely divided; the flowers are placed thinner in the ſpikes than thoſe of the upright ſort; they are large, and ſome of them very double and of various colours.

Theſe plants are annual, ſo are every year propagated by ſeeds, which ſhould be ſown where the plants are deſigned to remain, for they do not bear tranſplanting well, eſpecially if they are not removed very young; thoſe ſeeds which are ſown in autumn, produce the ſtrongeſt plants and moſt double flowers, and ripen their ſeeds better than thoſe which are ſown in the ſpring, as they come earlier to flower; but to continue a ſucceſſion of theſe flowers, there ſhould be ſome ſeeds ſown in the ſpring. When they are ſown on the borders of the flower-garden for ornament, they ſhould be in patches of about a foot diameter, in the middle of the borders, at proper diſtances; in each of theſe patches may be ſcattered ten or a dozen ſeeds, covering them over about a quarter of an inch with earth; and in the ſpring the plants may be thinned, leaving about five or ſix of the upright ſort in each patch to ſtand for flowering; but of the branching ſort, not more than three or four, becauſe theſe require room; after this the plants will require no farther care but to keep them clean from weeds, and when they begin to flower ſhould be ſupported by flower-ſticks to prevent their being broken by wind, eſpecially if they are not in a ſheltered ſituation. If the ſeeds were well choſen, there will be very few ordinary flowers among them; and if there are ſeeds of the different coloured flowers ſown in each patch, they will make a pleaſing variety: but the upright ſort ſhould never be mixed in the ſame patches with the branching, becauſe they do not flower at the ſame time.

But in order to preſerve the two ſorts fine without degenerating to ſingle or bad colours, there ſhould be a bed of each ſort ſown in autumn, in ſome ſeparate part of the garden, where the plants ſhould be properly thinned, and kept clean from weeds, till they begin to ſhew their flowers; when they ſhould be carefully looked over every other day, to pull out all thoſe plants, whoſe flowers are not very double nor of good colours; for if theſe are permitted to ſtand among the others till their farina has impregnated them, it will certainly cauſe them to degenerate; ſo that thoſe perſons who are contented with only marking their good flowers for ſeed, and ſuffer the others to ſtand for ſeed among them, will always find themſelves diſappointed in the goodneſs of their flowers the following ſeaſon: therefore thoſe who propoſe to have theſe flowers in perfection, ſhould never gather the ſeeds of ſuch as grew in the borders of the flower-garden; becauſe there it will be almoſt impoſſible to preſerve them ſo true, as when they are in beds at a diſtance from all other kinds.

When the ſeed-veſſels turn brown, they muſt be carefully watched, to gather them before they open and diſcharge the ſeeds; ſo that thoſe which are ſituated on the lower part of the ſtalk, will open long before thoſe on the upper part of the ſtalk are ripe; for which reaſon the pods ſhould from time to time be gathered as they ripen, and not ſuffered to ſtand till the ſtalks are pulled up, which is often practiſed. Thoſe pods which are ſituated on the lower part of the ſtalks, are much preferable to ſuch as grow near the top; for which reaſon thoſe who are very curious in the choice of their ſeeds, crop off the upper part of the ſpikes of flowers, and never ſuffer them to ſtand for ſeeds.

As theſe plants are very hardy, and require ſo little care in their culture, ſo they are worthy of a place in every good garden; for during their continuance in flower, there are few plants which make a better appearance; and for gathering to make flower-pots to adorn rooms, there is ſcarce any flower ſo proper; becauſe by their upright growth and long ſpikes, they riſe to a proper height above the pots; and when the ſeveral colours are ſkilfully intermixed they make a rich appearance, and continue long in beauty.

The fourth ſort grows naturally in Sicily and Spain, I received the ſeeds of it from Gibraltar; this hath a very branching ſtalk, which riſes about two feet high; the lower leaves are divided into many broad obtuſe ſegments, but thoſe which are upon the ſtalks are generally ſingle; the flowers grow ſcatteringly toward the upper part of the branches, they are ſmall, and of a deep blue colour; theſe are ſucceeded by very ſmall ſeed-veſſels, which are ſometimes ſingle, and at others double, and very rarely three together, as in the common ſorts. This is an annual plant, whoſe ſeeds ſhould be ſown in autumn, and the plants treated as the common ſort; it hath little beauty, and is only kept in ſome gardens for the ſake of variety.

The fifth ſort hath a perennial root, which ſends out ſeveral upright ſtalks in the ſpring, riſing to the height of four feet, garniſhed with leaves which are divided into many broad ſegments, in form of a ſpreading hand; theſe ſegments are cut at their extremities into two or three acute points; the leaves are hairy, and ſtand upon long foot-ſtalks; the flowers terminate the ſtalks, growing in long ſpikes; they are of a light blue, covered toward their hinder part with a meally down. This flowers in July and Auguſt, and in autumn the ſtalks decay to the root.

The ſixth ſort grows naturally in Siberia, from whence the ſeeds were ſent to the Imperial garden at Peterſburgh, where they ſucceeded; and the ſeeds were ſent me from thence by the late Dr. Amman, who was profeſſor of botany in that univerſity. This hath a perennial root, which puts out two or three branching ſtalks every ſpring; theſe riſe about a foot and a half high, and are garniſhed at each joint with leaves compoſed of many narrow ſegments, which terminate with ſeveral acute points; they are ſmooth, and of a light green colour; the flowers come out toward the upper part of the ſtalks ſingly, each ſtanding upon a long naked foot-ſtalk; theſe are large, and of a fine azure colour; they appear the latter part of July, and are ſucceeded by ſeeds which ripen in the autumn.

The ſeventh ſort grows naturally in America; this is a perennial plant, which riſes with ſtrong branching ſtalks ſix or ſeven feet high, garniſhed with hand-ſhaped leaves, which are divided into four or five broad lobes, ending with many acute points; theſe are ſmooth, and ſtand upon long foot-ſtalks; the flowers terminate the ſtalks, growing in long ſpikes; they are of a fine blue colour, with a bearded nectarium, having two lips; and of a dark colour, reſembling at a ſmall diſtance the body of a bee.

All the perennial Larkſpurs are propagated by ſeeds, which, if ſown in autumn, will more certainly ſucceed, than thoſe which are ſown in the ſpring; when the plants come up, they ſhould be kept clean from weeds, and where they are too cloſe together, part of them ſhould be drawn out, to allow room for the others to grow till the following autumn, when they muſt be planted where they are to remain; the following ſummer they will flower, and the roots continue many years growing in magnitude, ſo will produce a greater number of flower-ſtalks.

The eighth ſort is an annual plant, which grows naturally in the Levant, as alſo in Calabria; this riſes with a ſtrong hairy ſtalk about two feet high, garniſhed with hand-ſhaped hairy leaves, compoſed of five or ſeven oblong lobes, which have frequently one or two acute indentures on their ſides; the flowers form a looſe ſpike at the upper part of the ſtalk, each ſtanding on a long foot-ſtalk; the flowers are of a pale blue or purple colour, and have a two-leaved nectarium: this is propagated by ſeeds, which ſhould be ſown in autumn, for thoſe ſown in the ſpring never grow the ſame year. The ſeeds ſhould be ſown where the plants are to remain, and require no other treatment than the common Larkſpur. The common people uſe the powder of this ſeed to kill lice, from whence it has been titled Louſewort.

DENS CANIS. See Erythronium.

DENS LEONIS. See Leontodon.

DENTARIA. Lin. Gen. Plant. 726. Tourn. Inſt. R. H. 225. tab. 110. Toothwort; in French *Dentaire.*

The Characters are,

The empalement of the flower is compoſed of four oblong oval leaves, which fall off; the flower hath four obtuſe petals placed in form of a croſs; it hath ſix ſtamina, four of which are as long as the empalement, the other two are ſhorter; theſe are terminated by oblong heart-ſhaped ſummits, which ſtand erect. In the center is ſituated an oblong germen, ſupporting a ſhort thick ſtyle, crowned by an obtuſe ſtigma; the germen afterward becomes a long taper pod with two cells, divided by an intermediate partition, opening with two valves, including many roundiſh ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliquoſa, the flowers having four long and two ſhort ſtamina, and the ſeeds being incloſed in long pods.

The Species are,

1. Dentaria (*Pentaphyllos*) foliis ſummis digitatis. Lin. Sp. 912. *Five-leaved Toothwort, whoſe upper leaves are hand-ſhaped.* Dentaria pentaphyllos, foliis mollioribus. C. B. P. 322. *Five-leaved Toothwort with ſoft leaves.*
2. Dentaria (*Bulbifera*) foliis inferioribus pinnatis, ſummis ſimplicibus. Hort. Cliff. 335. *Toothwort with lower leaves winged, and the upper ones ſingle.* Dentaria

ria heptaphyllos baccifera. C. B. P. 322. *Seven-leaved bulb-bearing Toothwort.*

3. **Dentaria** (*Enneaphyllos*) foliis ternis ternatis. Lin. Sp. Plant. 653. *Toothwort with three-leaved trifoliate leaves.* Dentaria triphyllos. C. B. P. 322. *Three-leaved Toothwort.*

The firſt ſort riſes with a ſtrong ſtalk a foot and a half high, garniſhed with a leaf at each joint, compoſed of five lobes, which are four inches long, and near two broad in the wideſt part, ending in acute points, deeply ſawed on their edges; theſe are ſmooth, and ſtand on long foot-ſtalks; the flowers grow in looſe ſpikes at the top of the ſtalks; they are ſmall, of a bluſh colour, and ſucceeded by long taper pods filled with ſmall roundiſh ſeeds. It grows in the ſhady woods in the ſouth of France and Italy.

The ſecond ſort riſes with ſlender ſtalks about a foot high; the leaves at the bottom have ſeven lobes, thoſe a little above five, others but three, and at the upper part of the ſtalk they are ſingle: the flowers grow in cluſters at the top of the ſtalk; theſe have four obtuſe purple petals, and are ſucceeded by taper pods filled with roundiſh ſeeds.

The third ſort riſes with an upright ſtalk a foot high; the leaves are compoſed of nine lobes, three growing together, ſo that one leaf has three times three; the flowers grow in ſmall bunches on the top of the ſtalks, and are ſucceeded by ſmall taper pods filled with roundiſh ſeeds.

Theſe plants grow on the mountains in Italy, and in the woods of Auſtria. The ſecond ſort is found wild in ſome parts of England, but particularly near Hare-field, in moiſt ſhady woods, and is ſeldom preſerved in gardens: this produces bulbs on the ſide of the ſtalks, where the leaves are ſet on, which, if planted, will grow and produce plants. Theſe plants are propagated by ſeeds, or parting their roots; the ſeeds ſhould be ſown in autumn, ſoon after they are ripe, in a light ſandy ſoil and a ſhady ſituation: in the ſpring the plants may be taken up where they grow too cloſe, and tranſplanted out in the like ſoil and ſituation; where, after they have taken root, they will require no farther care, but to keep them clear from weeds: the ſecond year they will produce flowers, and ſometimes perfect their ſeeds.

The beſt time to tranſplant the roots is in October, when they ſhould be planted in a moiſt ſoil and a ſhady ſituation; for they will not live in a dry ſoil, or when they are expoſed to the ſun.

DEW is by ſome defined to be a meteor bred of a thin cold vapour, or compoſed of the ſteams and vapours of the earth; which, being exhaled by the heat of the ſun, and kept ſuſpended during his preſence, do, upon his abſence, convene into drops, and then fall down unto the earth again.

Others define it, a thin, light, inſenſible miſt or rain, falling while the ſun is below the horizon.

The origin and matter of dews are, without doubt, from vapour and exhalations of the earth and water, raiſed by the warmth of the ſun and earth, &c.

There being many vapours in the air, though not always viſible, hence it comes to paſs, that even in clear weather great dews fall, eſpecially in countries where it ſeldom rains; for when it happens that the ſcattered vapours are collected and condenſed together, and forced downwards, they muſt needs fall, and bedew the plants and graſs.

The thin veſicles, of which vapours conſiſt, being once detached from their bodies, keep riſing in the air till they arrive at ſuch a ſtage as is of the ſame ſpecific gravity with themſelves, when their riſe is ſtopped: now, as it is the warmth or fire that dilates the parts of water, and forms thoſe veſicles that are ſpecifically lighter than the air, and are capable of aſcending therein; ſo when that heat declines, or is loſt, as by the approach or contiguity of any colder body, the veſicles condenſe, and become heavier and deſcend.

Therefore the ſun warming the atmoſphere in the day-time, by the continual influx of his rays, the vapours being once raiſed, continue their progreſs, not meeting with any thing to increaſe their gravity, till ſuch time as they are got far beyond the reach of the reflected warmth of the earth in the middle region of the atmoſphere, and there condenſe and form clouds.

Though ſome ſay, it is diſputable whether dews ever congregate ſo as to form clouds, as they are only elevated by the ſun; ſo that when that power is gone, as it is after the ſetting of the ſun, they immediately deſcend; and this is more obſervable in very warm weather, and very hot climates.

The time for the falling of the dew is either before ſun-riſing, or after ſun-ſet; that it may regularly fall at ſuch times, it is neceſſary for the air to be calm, for windy or ſtormy weather hinders it; but when it is calm weather, and gentle breezes are felt from the weſt about the ſetting, and from the eaſt about the riſing of the ſun, it is probable, that by moderately cooling the air, they collect the vapours and precipitate them; and becauſe the morning breezes are more general than the evening ones, for this reaſon the evening dews fall only here and there, but thoſe in the morning ſeldom fail to be univerſal: or, as it may be otherwiſe expreſſed, when the ſun is got below the horizon, the atmoſphere cools the vapours, which have in the preceding day been raiſed by the warmth of the earth; and the rays of the ſun being lodged there, as ſoon as they are got out of the air, they begin to condenſe apace, and ſpend their ſtock of heat and fire on the cold moiſt air that they paſs through.

Hence it is, that dews are more copious in the ſpring than other ſeaſons, there being a greater ſtock of vapour in readineſs, by reaſon there has been but a ſmall expence thereof during the winter's cold and froſt than at other times.

It is found by experience, that the dews are more copious in hotter countries than in cold, as Pliny obſerves of the ſummer nights in Africa, which he calls Roſcidæ æſtate noctes; the reaſon of which ſeems to be this, that in the day-time the heat of the ſun raiſes abundance of vapours out of the water; which vapours are ſo extremely rarefied by the ſame heat, that they are diſperſed far and wide; but the cool of the night brings them together, and condenſes them to that degree, that they fall to the ground, but not in ſuch large drops as rain does; but in colder countries, where there are frequent rains, and the vapours are leſs rarefied, moſt of them come down in rain, and but a ſmall part turns to dew: beſides, in Africa there is a great difference between the heat of the day and night, particularly in ſummer; for their nights are long, and very cold; whereas in northern countries they are little colder than the day, and much ſhorter than in places nearer the line.

Pliny likewiſe relates of Egypt, that it abounds in dews throughout all the heat of ſummer; for the air being there too hot to conſtipate the vapours in the day-time, they never gather into clouds, and for that reaſon they have no rain. But it is known, in climates where the days are exceſſive hot, the nights are remarkably cold, ſo that the vapours that are raiſed after ſun-ſet are readily condenſed into dews: or, perhaps notable coldneſs may be rather the effect than the cauſe of the quantity of dews; for much vapour being raiſed by the great heat of the earth, and the ſtock of fire being ſpent on it in the day-time, the influx of ſuch a great quantity of moiſture muſt greatly chill the air.

The difference between dew and rain ſeems to be only this, that dew falls at ſome particular times as aforeſaid, and in very ſmall drops, ſo as to be ſeen when down, but ſcarce perceivable while it is falling; whereas rain falls at any time, and in groſſer drops.

The reverend Dr. Hales, in his Treatiſe of Vegetable Statics, tells us, That in order to find out the quantity of dew that fell in the night on the 15th of Auguſt, 7 p. m. he took two glazed earthen pans, which were three inches deep, and twelve inches diameter in ſurface: that he filled them with pretty moiſt earth, taken off the ſurface of the ground, and they increaſed in weight by the night's dew 180 grains; and decreaſed in weight by the evaporation of the day 1 ounce + 282 grains.

He ſays likewiſe, he ſet theſe in other broader pans to prevent any moiſture from the earth ſticking to the bottom of them. He adds, that the moiſter the earth is, the more dew falls on it in a night, and more than a double quantity of dew falls on a ſurface of water than there does on an equal ſurface of moiſt earth. The evaporation of a ſurface of water in nine hours winter's dry day, is $\frac{1}{31}$ of an inch: the evaporation of a ſurface of ice ſet in the ſhade during a nine hours day, was $\frac{1}{31}$.

So here are 540 grains more evaporated from the earth every 24 hours in ſummer than fall in dew in the night; that is, in 21 days near 26 ounces from a circular area of a foot diameter; and circles being as the ſquares of their diameters, 10 pounds + 2 ounces will in 21 days be evaporated from the hemiſphere of 30 inches diameter, which the Sunflower's root occupies; which, with the 29 pounds drawn off by the plant in the ſame time, makes 39 pounds, that is, 9 pounds and $\frac{3}{4}$ out of every cubic foot of earth, the plant's roots occupying more than 4 cubic feet: but this is a much greater degree of drineſs than the ſurface of the earth ever ſuffers for 15 inches depth, even in the drieſt ſeaſons in this country.

In a long dry ſeaſon therefore, eſpecially within the tropics, we muſt have recourſe, for ſufficient moiſture to keep plants and trees alive, to the moiſt ſtrata of earth, which lie next below that in which the roots are.

Now moiſt bodies always communicate of their moiſture to more dry adjoining bodies; but this ſlow motion of the aſcent of moiſture is much accelerated by the ſun's heat to conſiderable depths in the earth, as is probable, he ſays, from the twentieth experiment in the ſaid book.

Now 180 grains of dew falling in one night on a circle of a foot diameter = 113 ſquare inches; theſe 180 grains being equally ſpread on this ſurface, its depth will be $\frac{1}{159}$ part of an inch $= \frac{180}{113 \times 254}$. He adds, that he found the dew in a winter night to be the $\frac{1}{90}$ part of an inch; ſo that if we allow 151 nights for the extent of the ſummer dew, it will in that time ariſe to one inch depth: and reckoning the remaining 214 nights for the extent of the winter's dew, it will produce 2,39 inches depth, which makes the dew of the whole year amount to 3,39 inches depth.

And the quantity which evaporated in a fair ſummer's day from the ſame ſurface, being as 1 ounce 282 grains, gives $\frac{1}{40}$ part of an inch depth for evaporation, which is four times as much as fell at night.

He ſays likewiſe, that he found by the ſame means, the evaporation of a winter's day to be nearly the ſame as in a ſummer's day; for the earth being in winter more ſaturate with moiſture, that exceſs of moiſture anſwers to the exceſſive heat in ſummer.

Nic. Cruquius, N° 381. of the Philoſophical Tranſactions, found, that 28 inches depth evaporated in a whole year from water, i. e. $\frac{1}{12}$ of an inch each day at a mean rate: but the earth in a ſummer's day evaporates $\frac{1}{40}$ of an inch, ſo the evaporation of a ſurface of water is to the evaporation of a ſurface of earth in ſummer as 10 : 3.

The quantity of rain and dew that falls in a year is at a medium 22 inches. The quantity of the earth's evaporation in a year is at leaſt 9 + $\frac{1}{2}$ inches; ſince that is the rate at which it evaporates in a ſummer's day: from which 9 + $\frac{1}{2}$ inches are to be deducted 3,39 inches for circulating daily dew, there remains 6,2 inches; which 6,2 inches deducted from the quantity of rain that falls in a year, there remains at leaſt 16 inches depth to repleniſh the earth with moiſture for vegetation, and to ſupply the ſprings and rivers.

Dr. Hales proceeds to inſtance, in the caſe of a Hop-ground which he gives in the ninth experiment of his book of Vegetable Statics, that the evaporation there found, from the Hops, conſidered only for three months, at $\frac{1}{101}$ part of an inch each day, which will be $\frac{9}{10}$ of an inch: but before it be allowed 6,2 inches to form the ſurface of the ground, which added to the $\frac{9}{10}$ give 7,1 inches, which is the utmoſt that can be evaporated from a ſurface of Hop-ground in a year; ſo that of 22 inches depth of rain, there remain 15 inches to ſupply ſprings, which are more or leſs exhauſted, according to the drineſs or wetneſs of the year.

Hence we find, that 22 inches depth of rain in a year is ſufficient for all the purpoſes of nature in ſuch flat countries as that about Teddington near Hampton Court. But in the hill countries, as in Lancaſhire, there falls 42 inches depth of rain water, from which, deducting 7 inches for evaporation, there remains 35 inches depth of water for the ſprings, beſides great ſupplies from much more plentiful dews than fall in plain countries; which vaſt ſtores ſeem ſo abundantly ſufficient to anſwer the great quantity of water, which is conveyed away by the ſprings and rivers from thoſe hills, that we need not have recourſe for ſupplies to the great abyſs, whoſe ſurface at high water is ſurmounted ſome hundreds of feet by thoſe vaſt hills from whence the longeſt and greateſt rivers take their riſe.

DIANTHERA. Lin. Gen. Plant. 37. Flor. Virg. 6.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is tubulous, and cut at the top into five equal parts; the flower is of the grinning kind, having one petal with a ſhort tube; the upper lip is reflexed and bifid, the lower is divided into three parts, the middle being the broadeſt; it hath two ſhort ſlender ſtamina adhering to the back of the petal, one of theſe hath a twin ſummit, the other is a little taller. It hath an oblong germen, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by an obtuſe ſtigma. The empalement afterward becomes a capſule with two cells, opening with two valves, which are alternately compreſſed at the top and bottom, and open with an elaſticity, caſting a ſingle flat ſeed out of each cell.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, intitled Diandria Monogynia, the flower having two ſtamina and one ſtyle. This is one of the genera which, by Linnæus's method, is ſeparated to a great diſtance from their congeners; for by all their other characters they ſhould be joined to his fourteenth claſs, but having only two ſtamina, they are put under his ſecond.

We know but one SPECIES of this genus at preſent, viz.

DIANTHERA (*Americana*) ſpicis ſolitariis alternis. Lin. Sp. 24. *Dianthera with ſolitary alternate ſpikes.*

This plant grows naturally in Virginia, and other parts of North America, from whence the ſeeds have been ſent to England, where they have ſucceeded. This is a low herbaceous plant with a perennial root, which ſends out ſeveral weak ſtalks about four inches long, garniſhed with roundiſh leaves of an aromatic odour, ſtanding cloſe to the ſtalks; they are hairy, and of a dark green colour; from the ſide of the ſtalks the flowers are produced in ſmall ſpikes, placed alternately; theſe are in ſhape and colour very like thoſe of the Clinopodium, but have only two ſtamina in each. It flowers the latter end of July, but rarely produces ſeeds in England.

This plant is very difficult to preſerve in this country, for although it is hardy enough to live in the open air in England, yet it is very ſubject to rot in winter; and if it is placed under ſhelter, it is apt to draw up weak, and ſoon after decay, ſo that at preſent the plants are rare in this country.

DIANTHUS. Lin. Gen. Plant. 500. Caryophyllus. Tourn. Inſt. R. H. 329. Clove Gilly Flower, Carnation Pink; in French, *Oeillet.*

The Characters are,

The flower hath a long cylindrical empalement which is permanent; it hath five petals, whoſe tails are as long as the empalement, but their upper part is broad, plain, and crenated on their borders; theſe are inſerted in the bottom of the tube, and ſpread open above. It hath ten ſtamina which are as long as the empalement, terminated by oblong compreſſed ſummits. In the center is ſituated an oval germen, ſupporting two ſtyles which are longer than the ſtamina, crowned by recurved ſtigmas. The germen afterward becomes a cylindrical capſule with one cell, opening in four parts at the top, and filled with compreſſed angular ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's tenth claſs, intitled Decandria Digynia, the flowers having ten ſtamina and two ſtyles.

The Species are,

1. Dianthus (*Deltoides*) floribus ſolitariis, ſquamis calycinis lanceolatis binis, corollis crenatis. Hort. Cliff. 164. *Dianthus with a ſingle flower having a double ſcaly empalement, and crenated petals.* Caryophyllus ſylveſtris vulgaris latifolius. C. B. P. 209. *Maiden Pink.*
2. Dianthus (*Virgineus*) caule ſubunifloro, corollis crenatis, ſquamis calycinis breviſſimis, foliis ſubulatis. Lin. Sp. Plant. 412. *Dianthus with one flower on a ſtalk, crenated petals, very ſhort ſcales to the empalement, and awl-ſhaped leaves.* Caryophyllus minor repens. Noſtras. Raii. Syn. 335. *Engliſh ſmall creeping Pink, commonly called the matted Pink by ſeedſmen.*
3. Dianthus (*Glaucus*) floribus ſubſolitariis, ſquamis calycinis lanceolatus quaternis, corollis crenatis. Hort. Cliff. 164. *Dianthus with one flower on a ſtalk, having four ſpear-ſhaped ſcales to the empalement, and crenated petals.* Tunica ramoſior flore candido cum corollâ purpureâ. Hort. Elth. 400. *Branching Pink with a white flower, having a purple circle, commonly called Mountain Pink.*
4. Dianthus (*Plumarius*) floribus ſolitariis, ſquamis calycinis ſubovatis breviſſimis, corollis multifidis fauce pubeſcentibus. Lin. Sp. Plant. 411. *Dianthus with a ſingle flower, having ſhort oval ſcales to the empalement, and petals cut into many points, with a hairy bottom.* Caryophyllus ſimplex flore minore pallido rubente. C. B. P. 208. *Single wild Pink, with a ſmall, pale, reddiſh flower.*
5. Dianthus (*Caryophyllus*) floribus ſolitariis ſquamis calycinis ſubovatis breviſſimis, corollis crenatis. Hort. Cliff. 164. *Dianthus with a ſingle flower, having ſhort oval ſcales to the empalement, and crenated petals.* Caryophyllus hortenſis ſimplex, flore majore. C. B. P. 208. *Single Garden Carnation with a large flower.*
6. Dianthus (*Armeria*) floribus aggregatis faſciculatis, ſquamis calycinis lanceolatis villoſis tubum æquantibus. Hort. Cliff. 165. *Dianthus with many flowers gathered into bunches, having hairy ſpear-ſhaped ſcales to the empalement, as long as the tube of the flower.* Caryophyllus barbatus ſylveſtris. C. B. P. 208. *Bearded wild Pink, called Deptford Pink.*
7. Dianthus (*Barbatus*) floribus aggregatis faſciculatis, ſquamis calycinis linearibus, foliis lanceolatis. *Dianthus with many flowers gathered in bunches, having very narrow ſcales to the empalement, and ſpear-ſhaped leaves.* Caryophyllus barbatus hortenſis latifolius. C. B. P. 208. *Broad-leaved Garden Sweet William.*
8. Dianthus (*Prolifer*) floribus aggregatis capitatis, ſquamis calycinis ovatis obtuſis muticis tubum ſuperantibus. Lin. Sp. Plant. 587. *Dianthus with flowers collected into heads, and obtuſe, oval, chaffy ſcales to the empalements, which are longer than the tube.* Caryophyllus ſylveſtris prolifer. C. B. P. 209. *Wild childing Sweet William.*
9. Dianthus (*Ferrugineis*) floribus aggregatis capitatis, ſquamis calycinis lanceolatis ariſtatis, corollis crenatis. *Dianthus with flowers collected in heads, having ſpear-ſhaped ſcales to the empalement which are bearded, and crenated petals.* Caryophyllus montanus umbellatus, floribus variis luteis ferrugineis Italicus. Barrel. Obſ. 648. *Italian umbellated Mountain Pink, with flowers varying from yellow to an iron colour.*
10. Dianthus (*Chinenſis*) floribus ſolitariis, ſquamis calycinis ſubulatis patulis, tubum æquantibus, corollis crenatis. Hort. Cliff. 164. *Dianthus with a ſingle flower on each ſtalk, awl-ſhaped ſpreading ſcales to the empalement equalling the tube, and crenated petals.* Caryophyllus ſinenſis ſupinus, leucoii folio, flore unico. Tourn. Act. Par. 1705. *The China Pink.*
11. Dianthus (*Arenarius*) caulibus unifloris ſquamis calycinis ovatis obtuſis, corollis multifidis, foliis linearibus. Flor. Suec. 318. *Dianthus having a ſingle flower upon a ſtalk, oval ſcales to the empalement, the petals of which are cut into many points, and narrow leaves.* Caryophyllus ſylveſtris humilis, flore unico. C. B. P. 209. *Dwarf wild Pink with one flower.*
12. Dianthus (*Alpinus*) caule unifloro, corollis crenatis, ſquamis calycinis exterioribus tubum æquantibus, foliis linearibus obtuſis. Lin. Sp. Plant. 412. *Dianthus with one flower having crenated petals, the outer ſcales of the empalement equalling the tube, and narrow obtuſe leaves.* Caryophyllus pumilus latifolius. C. B. P. 209. *Dwarf broad-leaved Pink.*
13. Dianthus (*Superbus*) floribus paniculatis, ſquamis calycinis brevibus acuminatis, corollis multifido-capillaribus, caule erecto. Amœn. Acad. 4. p. 272. *Dianthus with paniculated flowers, having ſhort-pointed ſcales to their empalement, multifid petals, and an upright ſtalk.*
14. Dianthus (*Diminutus*) floribus ſolitariis, ſquamis calycinis octonis florem ſuperantibus. Lin. Sp. 587. *Dianthus with a ſingle flower on each ſtalk, having eight ſcales which riſe above the petals of the flower.* Caryophyllus ſylveſtris minimus. Tabern. Hiſt. 290.

The firſt ſort hath creeping ſtalks, from which come out ſeveral tufted heads, cloſely garniſhed with narrow leaves, whoſe baſe lie over each other embracing the ſtalks; between theſe ariſe the flower-ſtalks, which grow about ſix inches high, garniſhed at every joint by two narrow graſſy leaves placed oppoſite. The ſtalks are terminated by a ſingle flower. It flowers in June and July, and the ſeeds ripen in autumn. This is rarely admitted into gardens, the flower having no beauty.

The ſecond ſort is a low trailing plant, whoſe ſtalks lie on the ground; theſe grow very cloſe together, and are garniſhed with ſhort, narrow, graſſy leaves of a deep green colour; the ſtalks are terminated by ſmall red flowers, each ſtanding upon a ſeparate footſtalk. It flowers in July, and the ſeeds ripen in September. This ſort grows naturally in ſeveral parts of England, ſo is not often cultivated in gardens at preſent; but formerly the ſeeds were ſown to make edgings for the borders of the flower-garden by the title of matted Pink, by which the ſeeds were ſold in the ſhops.

The third ſort grows naturally upon Chidder rocks in Somerſetſhire, and ſome other parts of England. This was formerly cultivated in the gardens by the title of Mountain Pink. It hath a reſemblance of the ſecond ſort, but the leaves are ſhorter, and of a grayiſh colour; the ſtalks grow taller, and branch more; the flowers are larger, of a white colour, with a purple circle in the bottom, like that ſort of Pink called Pheaſants Eye. As the flowers of this ſort have no ſcent, the plants are ſeldom kept in gardens.

The fourth ſort grows naturally in ſeveral parts of England, frequently upon old walls; it is a ſmall ſingle Pink, of a pale red colour, ſo is not cultivated in gardens.

The fifth ſort is a ſmall ſingle Carnation, which has been long caſt out of all the gardens; from one of this ſort it is ſuppoſed, many of the fine flowers now cultivated in the gardens have been raiſed.

The ſixth ſort grows naturally in ſeveral parts of England, and particularly in a meadow near Deptford in Kent, from whence it had the title of Deptford Pink. This is of the kind called Sweet William; the flowers of theſe grow in cluſters at the end of the branches; they are red, and have long bearded empalements. I have cultivated this ſort above forty years, and have never obſerved it to vary.

The ſeventh ſort is the common Sweet William, which has been long cultivated in the gardens for ornament, of which there are now great varieties which differ in the form and colour of their flowers, as alſo in the ſize and ſhape of their leaves; thoſe which have narrow leaves were formerly titled Sweet Johns by the gardeners, and thoſe with broad leaves were called Sweet Williams; there are ſome of both theſe ſorts with double flowers, which are very ornamental plants in gardens.

The eighth ſort grows naturally in the ſouth of France, in Spain, Italy, and in England. This is an annual plant, which riſes with an upright ſtalk about a foot high, garniſhed with narrow graſſy leaves, and is terminated by a ſmall head or cluſter of pale red flowers, which are included in one common ſcaly empalement. Theſe have little beauty, ſo the plants are ſeldom kept in gardens.

The ninth ſort is a biennial plant, which riſes with an upright ſtalk a foot and a half high, having two long narrow leaves placed oppoſite at each joint, which embrace the ſtalk with their baſe; they are of a deep green colour, ſtiff, and end in acute points. The flowers grow in cloſe cluſters at the top of the ſtalks, having ſtiff bearded empalements; they are yellow and iron coloured intermixed on the ſame ſtalk, and frequently they are of both colours in the ſame head. This plant flowers in July, and the ſeeds ripen in autumn.

The tenth ſort came originally from China, ſo it is titled the China Pink; the flowers of this have no ſcent, but there are a great variety of lively colours among them; and of late years there has been great improvements made in the double flowers of this ſort, ſome of which are as full of petals as the double Pink, and their colours are very rich. The plants ſeldom grow more than eight or nine inches high, branching out on every ſide; the branches grow erect, and are terminated each by a ſingle flower. Theſe flower in July, and continue in ſucceſſion till the froſt ſtops them; they are commonly raiſed every year from ſeeds, but the roots will continue two years in dry ground.

The eleventh ſort is found growing naturally upon old walls and buildings in many parts of England; this is a ſingle ſmall Pink, of a ſweet odour, but of a pale colour and ſmall, ſo makes no appearance; and ſince the great improvement which has been made in theſe flowers by culture, this has been entirely neglected.

The twelfth ſort grows naturally on the Alps. This hath round, ſhort, blunt leaves; the ſtalks ſeldom riſe more than four inches high, each being terminated by a ſingle flower of a pale red colour. It is ſometimes preſerved in botanic gardens for the ſake of variety, but is rarely admitted into other gardens.

The thirteenth ſort grows naturally in Germany and Denmark; the leaves of this ſort are like thoſe of the narrow-leaved Sweet William; the ſtalk riſes more than a foot high, and is terminated by a ſingle flower, having five large petals of a pale red colour, which are cut into many long ſegments. The roots of this ſort will live three or four years, but the ſecond year from ſeeds they are in greateſt beauty; therefore as the ſeeds ripen well in England, young plants ſhould be annually raiſed.

The fourteenth ſort is a very diminutive plant, having ſhort narrow leaves growing in cloſe heads; the ſtalk ſeldom riſes ſix inches high, which is terminated by a ſingle flower, of a pale red colour, ſo has little beauty, therefore is only kept in botanic gardens for variety.

The ſorts here enumerated, are ſuch as the botaniſts allow to be diſtinct ſpecies; and all the varieties of fine flowers, which are now cultivated in the gardens of the curious, are only accidental variations which have been produced by culture; and the number of theſe are greatly increaſed annually, in many different parts of Europe; ſo that as new varieties are obtained, the old flowers are rejected.

The plants of this genus may be properly enough divided into three ſections. The firſt to include all the variety of Pinks, the ſecond all the Carnations, and the third thoſe of the Sweet William; for although theſe agree ſo nearly in their principal characters, as to be included under the ſame genus by the botaniſts, yet they never vary from one to the other, though they frequently change and vary in the colour of their flowers.

I ſhall now proceed to treat of theſe under their different ſections, and firſt I ſhall begin with the Pink, of which there are a great variety now cultivated in the gardens; the principal of which are, the damaſk Pink, the white Shock, the Pheaſant Eye, with double and ſingle flowers, varying greatly in their ſize and colour; the common red Pink, Cob's Pink, Dobſon's Pink, white Cob Pink, and Bat's Pink. The old Man's Head, and painted Lady Pink, rather belong to the Carnation.

The damaſk Pink is the firſt of the double ſorts in flower. This hath but a ſhort ſtalk; the flower is not very large, and not ſo double as many others; the colour is of a pale purple, inclining to red, but is very ſweet.

The next which flowers is the white Shock, which was ſo called from the whiteneſs of its flowers, and the borders of the petals being much jagged and fringed; the ſcent of this is not ſo agreeable as of ſome others.

Then comes all the different kinds of Pheaſants Eye, of which there are frequently new varieties raiſed, which are either titled from the perſons who raiſed them, or the place where they were raiſed; ſome of theſe have very large double flowers, but thoſe which burſt their pods are not ſo generally eſteemed.

The Cob Pink comes after theſe to flower; the ſtalks of this are much taller than thoſe of any of the former; the flowers are very double, and of a bright red colour; theſe have the moſt agreeable odour of all the ſorts, ſo merits a place in every good garden. The time of the Pinks flowering is from the latter end of May to the middle of July, and frequently that ſort of Pheaſant Eye, which is called Bat's Pink, will flower again in autumn.

The old Man's Head Pink, and the painted Lady, do not flower till July, coming at the ſame ſeaſon with the Carnation, to which they are more nearly allied than the Pink. The firſt when it is in its proper colours, is purple and white ſtriped and ſpotted, but this frequently is of one plain colour which is purple; this ſort will continue flowering till the froſt in autumn puts a ſtop to it, and the flowers having an agreeable ſcent, renders them valuable. The painted Lady is chiefly admired for the livelineſs of its colour, for it is not ſo ſweet, or of ſo long continuance as the other.

The common Pinks are propagated either by ſeeds, which is the way to obtain new varieties, or by making layers of them, as is practiſed for Carnations; or by planting ſlips, which, if carefully managed, will take root very well.

If they are propagated by ſeeds, there ſhould be care taken in the choice of them, and only the ſeeds of the beſt ſorts ſaved, where the perſons are curious to have the fineſt flowers. Theſe ſeeds may be ſown in the ſpring, and the plants afterward treated in the ſame manner as is hereafter directed for the Carnation; with this difference only, that as the Pinks are leſs tender, they may be more hardily treated. Thoſe which are propagated by layers, muſt be alſo managed as the Carnation, for which there are full inſtructions hereafter given. The old Man's Head and painted Lady Pinks, are commonly propagated this way, but moſt of the other ſorts are propagated from ſlips.

The beſt time to plant the ſlips of Pinks is about end of July, when, if there ſhould happen rain, it will be of great ſervice to them; but if the weather ſhould prove dry, they will require to be watered every other day, until they have taken root; theſe ſhould be planted in a ſhady border, and the ground ſhould be dug well, and all the clods broken, and if no rain falls, it ſhould be well ſoaked with water a few hours before the ſlips are planted; then the ſlips ſhould be taken from the plants, and all their lower leaves ſtripped off, and planted as ſoon as poſſible after, for if they are ſuffered to lie long after they are taken from the plants, they will wither and ſpoil; theſe need not be planted at a greater diſtance than three inches ſquare, and the ground muſt be cloſed very hard about them; then they muſt be well watered, and this muſt be repeated as often as is found neceſſary, till the cuttings have taken root; after which they will require no other care but to keep them clean from weeds till autumn, when they ſhould be tranſplanted to the borders of the flower-garden where they are to remain. There are ſome who plant the ſlips of Pinks later in the ſeaſon than is here directed; but thoſe plants are never ſo ſtrong nor flower ſo well, as thoſe which are early planted.

We ſhall next proceed to the culture of the Carnation; theſe the floriſts diſtinguiſh into four claſſes.

The firſt they call Flakes; theſe are of two colours only, and their ſtripes are large, going quite through the leaves.

The ſecond are called Bizarrs; theſe have flowers ſtriped or variegated with three or four different colours, in irregular ſpots and ſtripes.

The third are called Piquettes; theſe flowers have always a white ground, and are ſpotted (or pounced, as they call it) with ſcarlet, red, purple, or other colours.

The fourth are called painted Ladies; theſe have their petals of a red or purple colour on the upper ſide, and are white underneath.

Of each of theſe claſſes there are numerous varieties, but chiefly of the Piquettes, which ſome years ago were chiefly in eſteem with the floriſts, but of late years the Flakes have been in greater requeſt than any of the other kinds. To enumerate the varieties of the chief flowers in any one of theſe claſſes, would be needleſs, ſince every country produces new flowers almoſt every year; ſo that thoſe flowers, which, at their firſt raiſing, were greatly valued, are in two or three years become ſo common, as to be of little worth, eſpecially if they are defective in any one property. Therefore (where flowers are ſo liable to mutability, either from the fancy of the owner, or that better kinds are yearly produced from ſeeds, which, with good floriſts, always take place of older or worſe flowers, which are turned out of the garden to make room for them) it would be but ſuperfluous in this place to give a liſt of their names, which are generally borrowed either from the names and titles of noblemen, or from the perſon's name, or place of abode, who raiſed it.

Theſe flowers are propagated either from ſeeds (by which new flowers are obtained), or from layers, for the increaſe of thoſe ſorts which are worthy maintaining; but I ſhall firſt lay down the method of propagating them from ſeeds, which is thus:

Having obtained ſome good ſeeds, either of your own ſaving, or from a friend that you can confide in, about the middle of April, prepare ſome pots or boxes (according to the quantity of ſeed you have to ſow); theſe ſhould be filled with freſh light earth mixed with rotten neats dung, which ſhould be well incorporated together; then ſow your ſeeds thereon (but not too thick) covering it about a quarter of an inch with the ſame light earth, placing the pots or caſes ſo as to receive the morning ſun only till eleven of the clock, obſerving alſo to refreſh the earth with water as often as it may require. In about a month's time your plants will come up, and if kept clear from weeds, and duly watered, will be fit to tranſplant about the latter end of July; at which time you ſhould prepare ſome beds (of the ſame ſort of earth as was directed to ſow them in) in an open airy ſituation, in which you ſhould plant them at about three inches ſquare, obſerving to water and ſhade them till they have taken new root, then you muſt obſerve to keep them clear from weeds; in theſe beds they may remain until the end of Auguſt, by which time they will have grown ſo large as almoſt to meet each other; then prepare ſome more beds of the like good earth (in quantity proportionable to the flowers you have raiſed) in which you ſhould plant them at ſix inches diſtance each way, and not above four rows in each bed, for the more conveniently laying ſuch of them as may prove worthy preſerving, for in theſe beds they ſhould remain to flower.

The alleys between theſe beds ſhould be two feet wide, that you may paſs between the beds to weed and clean them. If the ſeaſon ſhould prove very dry at this time, they ſhould not be tranſplanted till there is ſome rain; ſo that it may happen to be the middle, or latter end of September ſome years, before there may be wet enough to moiſten the ground for this purpoſe; but if there is time enough for the plants to get good root before the froſt comes on, it will be ſufficient. If the winter ſhould prove ſevere, the beds ſhould be arched over with hoops, that they may be covered with mats, otherwiſe many of the plants may be deſtroyed, for the good flowers are not ſo hardy as the ordinary ones of this genus. There will be no other culture wanting to theſe, but to keep them clean from weeds, and when they ſhoot up their ſtalks to flower, they muſt be ſupported by ſticks to prevent their breaking. When your flowers begin to blow, you muſt look over them to ſee which of them proffer to make good flowers, which as ſoon as you diſcover, you ſhould lay down all the layers upon them; thoſe which are well marked, and blow whole without breaking their pods, ſhould be reſerved to plant in borders, to furniſh you with ſeed; and thoſe which burſt their pods, and ſeem to have good properties, ſhould be planted in pots, to try what their flowers will be, when managed according to art; and it is not till the ſecond year that you can pronounce what the value of a flower will be, which is in proportion to the goodneſs of its properties; but, that you may be well acquainted with what the floriſts call good properties, I ſhall here ſet them down.

1. The ſtem of the flower ſhould be ſtrong, and able to ſupport the weight of the flower without hanging down.

2. The petals (or leaves) of the flower ſhould be long, broad, and ſtiff, and pretty eaſy to expand, or (as the floriſts term them) ſhould be free flowers.

3. The middle pod of the flower ſhould not advance too high above the other petals of the flower.

4. The colours ſhould be bright, and equally marked all over the flower.

5. The flower ſhould be very full of leaves, ſo as to render it, when blown, very thick and high in the middle, and the outſide perfectly round.

Having made choice of ſuch of your flowers as promiſe well for the large ſort, theſe you ſhould mark ſeparately for pots, and the round whole blowing flowers for borders; you ſhould pull up all ſingle flowers, or ſuch as are ill-coloured, and not worth preſerving, that your good flowers may have the more air and room to grow ſtrong; theſe having been laid at a proper ſeaſon, as ſoon as they have taken root (which will be ſome time in Auguſt) they ſhould be taken off, and planted out, thoſe that blow large, in pots, and the other in borders (as hath been already directed).

Of late years the whole-blowing flowers have been much more eſteemed than thoſe large flowers which burſt their pods, but eſpecially thoſe round flowers which have broad ſtripes of beautiful colours, and round Roſe leaves, of which kinds there have been a great variety introduced from France within theſe few years; but as theſe French flowers are extremely apt to degenerate to plain colours, and being much tenderer than thoſe which are brought up in England, there are not ſuch great prices given for the plants now, as have been a few years paſt; from the preſent taſte for theſe whole-blowing Flake flowers, many of the old varieties, which had been turned out of the gardens of the floriſts many years ago, to make room for the large flowers, which were then in faſhion, have been received again; and large prices have been paid of late for ſuch flowers as ſome years ago were ſold for one ſhilling a dozen, or leſs, which is a ſtrong proof of the variableneſs of the fancies of the floriſts.

But I ſhall now proceed to give ſome directions for propagating theſe flowers by layers, and the neceſſary care to be taken in order to blow them fair and large.

The beſt ſeaſon for laying theſe flowers is in June, as ſoon as the ſhoots are ſtrong enough for that purpoſe, which is performed in the following manner: after having ſtripped off the leaves from the lower part of the ſhoot intended to be laid, make choice of a ſtrong joint about the middle part of the ſhoot (not too near the heart of the ſhoot, nor in the hard part next the old plant); then with your penknife make a ſlit in the middle of the ſhoot from the joint upwards half way to the other joint, or more, according to their diſtance; then with your knife cut the tops of the leaves, and alſo cut off the ſwelling part of the joint where the ſlit is made, ſo that the part ſlit may be ſhaped like a tongue; for if that outward ſkin is left on, it would prevent their puſhing out roots; then having looſened the earth round the plant, and, if need be, raiſed it with freſh mould, that it may be level with the ſhoot intended to be laid down, leſt by the ground being too low, by forcing down the ſhoot you ſplit it off; then with your finger make a hollow place in the earth, juſt where the ſhoot is to come, and with your thumb and finger bend the ſhoot gently into the earth, obſerving to keep the top as upright as poſſible, that the ſlit may be open; and being provided with forked ſticks for that purpoſe, thruſt one of them into the ground, ſo that the forked part may take hold of the layer, in order to keep it down in its proper place; then gently cover the ſhank of the layer with the ſame ſort of earth, giving it a gentle watering to ſettle the earth about it, obſerving to repeat the ſame as often as is neceſſary, in order to promote their rooting. In about five or ſix weeks after this, the layers will have taken root ſufficient to be tranſplanted; againſt which time you ſhould be provided with proper earth for them, which may be compoſed after the following manner:

Make choice of ſome good up-land paſture, or a common that is of a hazel earth, or light ſandy loam; dig from the ſurface of this your earth about eight inches deep, taking all the turf with it; let this be laid in a heap to rot and mellow for one year, turning it once a month, that it may ſweeten; then mix about a third part of rotten neats dung, or for want of that, ſome rotten dung from a Cucumber or Melon-bed; let this be well mixed together, and if you can get it time enough before-hand, let them lie mixed ſix or eight months before it is uſed, turning it ſeveral times, the better to incorporate their parts.

Obſerve, that although I have mentioned this mixture as the beſt for theſe flowers, yet you muſt not expect to blow your flowers every year equally large in the ſame compoſition; therefore ſome people who are extremely fond of having their flowers ſucceed well, alter their compoſitions every year in this manner, viz. one year they mix the freſh earth with neats dung, which is cold; the next year with rotten horſe dung, which is of a warmer nature, adding thereto ſome white ſea ſand to make the earth lighter.

But, for my part, I ſhould rather adviſe the planting two or three layers of each of the beſt kinds in a bed of freſh earth not over dunged, which plants ſhould only be ſuffered to ſhew their flowers, that you may be ſure they are right in their kind and colours; and when you are ſatisfied in that particular, cut off the flower-ſtems, and do not ſuffer them to ſpend the roots in blowing, by which means you will ſtrengthen your layers. And it is from theſe beds I would make choice of ſome of the beſt plants for the next year's blowing, always obſerving to have a ſucceſſion of them yearly, by which means you may have every year fine flowers, provided the ſeaſon proves favourable: for it is not reaſonable to ſuppoſe, that the layers taken from ſuch roots as have been exhauſted in producing large flowers, and have been forced by art to the utmoſt of their natural ſtrength, ſhould be able to produce flowers equally as large as their mother root did the year before, or as ſuch layers as are freſh from a poorer ſoil, and in greater health can do.

But this being premiſed, let us proceed to the planting of theſe layers, which (as I ſaid before) ſhould be done in Auguſt, or the beginning of September.

The common method uſed by moſt floriſts is, to plant their layers at this ſeaſon, two in each pot (the ſize of which pots are about nine inches over in the clear at the top); in theſe pots they are to remain for bloom; and therefore, in the ſpring of the year, they take off as much of the earth from the ſurface of the pots as they can, without diſturbing their roots, filling the pots up again with the ſame good freſh earth as the pots were before filled with. But there is ſome difficulty in ſheltering a great quantity of theſe flowers in winter, when they are planted in ſuch large pots, which in moſt winters they will require, more or leſs; my method therefore is, to put them ſingly into halfpenny pots in autumn, and in the middle or latter end of October, to ſet theſe pots into a bed of old tanners bark, which has loſt its heat, and cover them with a common frame (ſuch as is uſed for raiſing Cucumbers and Melons); and in two of theſe frames, which contain ſix lights, may be ſet a hundred and fifty of theſe pots: in theſe frames you may give them as much free air as you pleaſe, by taking off the lights every day when the weather is mild, and putting them on only in bad weather and great rains; and if the winter ſhould prove ſevere, it is only the covering the glaſſes with mats, ſtraw, or Peaſe-haulm, ſo as to keep out the froſt, which will effectually preſerve your plants in the utmoſt vigour.

In the middle or latter end of February, if the ſeaſon is good, you muſt tranſplant theſe layers into pots for their bloom (the ſize of which ſhould be about eight inches over at the top in the clear); in the doing of which, obſerve to put ſome potſherds or oyſter-ſhells over the holes in the bottoms of the pots, to keep the earth from ſtopping them, which would detain the water in the pots to the great prejudice of the flowers: then fill theſe pots about half way with the ſame good compoſt as was before directed, and ſhake the plants out of the ſmall pots with all the earth about the roots; then with your hands take off ſome of the earth round the outſide of the ball, and from the ſurface taking off the fibres of the roots on the outſide of the ball of earth; then put one good plant exactly in the middle of each pot, ſo that it may ſtand well as to the height, i. e. not ſo low as to bury the leaves of the plant with earth, nor ſo high, that the ſhank may be above the rim of the pot; then fill the pot up with the earth before-mentioned, cloſing it gently to the plant with your hands, giving it a little water, if the weather is dry, to ſettle the earth about it; then place theſe pots in a ſituation where they may be defended from the north wind, obſerving to give them gentle waterings, as the ſeaſon may require.

In this place they may remain till the middle or latter end of April, when you ſhould prepare a ſtage of boards to ſet the pots upon, which ſhould be ſo ordered as to have little ciſterns of water round each poſt, to prevent the inſects from getting to your flowers in their bloom, which, if they are ſuffered to do, will mar all your labour, by deſtroying all your flowers in a ſhort time; the chief and moſt miſchievous inſect in this caſe is, the earwig, which will gnaw off all the lower parts of the petals of the flowers (which are very ſweet) and thereby cauſe the whole flower to fall to pieces; but ſince the making one of theſe ſtages is ſomewhat expenſive, and not very eaſy to be underſtood by ſuch as have never ſeen them, I ſhall deſcribe a very ſimple one, which I have uſed for ſeveral years, which anſwers the purpoſe full as well as the beſt and moſt expenſive one can do: firſt, prepare ſome common flat pans, about fourteen or ſixteen inches over, and three inches deep; place theſe two and two oppoſite to each other, at about two feet diſtance, and at every eight feet lengthways, two of theſe pans; in each of theſe whelm a flower-pot, which ſhould be about ſix inches over at the top, upſide-down, and lay a flat piece of timber, about two feet and a half long, and three inches thick, croſs from pot to pot, till you have finiſhed the whole length of your ſtage; then lay your planks lengthways upon theſe timbers, which will hold two rows of planks for the ſize pots which were ordered for the Carnations; and when you have ſet your pots upon the ſtage, fill the flat pans with water, always obſerving, as it decreaſes in the pans, to repleniſh it, which will effectually guard your flowers againſt inſects; for they do not care to ſwim over water, ſo that if by this, or any other contrivance, the paſſage from the ground to the ſtage, on which the pots are placed, is defended by a ſurface of water three or four inches broad, and as much in depth, it will effectually prevent theſe vermin from getting to the flowers.

This ſtage ſhould be placed in a ſituation open to the ſouth-eaſt, but defended from the weſt winds, to which theſe ſtages muſt not be expoſed, leſt the pots ſhould be blown down by the violence of that wind, which is often very troubleſome at the ſeaſon when theſe flowers blow; indeed they ſhould be defended by trees at ſome diſtance, from the winds of every point; but theſe trees ſhould not be too near the ſtage, nor by any means place them near walls, or tall buildings, for in ſuch ſituations the ſtems of the flowers will draw up too weak. About this time, viz. the middle of April, your layers will begin to ſhoot up for flower; you muſt therefore be provided with ſome ſquare deal ſticks, about four feet and a half long, which ſhould be thicker toward the bottom, and planed off taper at the top; theſe ſticks ſhould be carefully ſtuck into the pots as near as poſſible to the plant, without injuring it; then with a ſlender piece of baſs mat, faſten the ſpindle to the ſtick to prevent its being broken; this you muſt often repeat, as the ſpindle advances in height, and alſo obſerve to pull off all ſide ſpindles as they are produced, and never let more than two ſpindles remain upon one root, nor above one, if you intend to blow exceeding large. Toward the beginning of June your flowers will have attained their greateſt height, and their pods will begin to ſwell, and ſome of the earlieſt begin to open on one ſide; you muſt therefore obſerve to let it open in two other places at equal angles; this muſt be done ſo ſoon as you perceive the pod break, otherwiſe your flower will run out on one ſide, and be in a ſhort time paſt recovering, ſo as to make a complete flower, and in a few days after the flowers begin to open, you muſt cover them with glaſſes which are made for that purpoſe, in the following manner:

Upon the top of the glaſs, exactly in the center, is a tin collar, or ſocket, about three fourths of an inch ſquare, for the flower-ſtick to come through; to this ſocket are ſoldered eight ſlips of lead at equal diſtances, which are about ſix inches and a half long, and ſpread open at the bottom about four inches aſunder; into theſe ſlips of lead are faſtened ſlips of glaſs, cut according to the diſtances of the lead, which, when they are fixed in, are bordered round the bottom with another ſlip of lead quite round, ſo that the glaſs hath eight angles, with the ſocket in the middle, and ſpread open at the bottom about eleven inches wide.

When your flowers are open enough to cover with theſe glaſſes, you muſt make a hole through your flower-ſtick, exactly to the height of the under part of the pod, through which you ſhould put a piece of ſmall wire about ſix inches long, making a ring at one end of the wire to contain the pod, into which ring you ſhould fix the ſtem of the flower; then cut off all the tyings of baſs, and thruſt the ſtem of the flower ſo far from the ſtick, as may give convenient room for the flower to expand without preſſing againſt the ſtick; to which diſtance you may fix it, by turning your wire ſo as not to draw back through the hole; then make another hole through the ſtick, at a convenient diſtance above the flower, through which you ſhould put a piece of wire, an inch and a half long, which is to ſupport the glaſſes from ſliding down upon the flowers; and be ſure to obſerve, that the glaſſes are not placed ſo high as to admit the ſun and rain under them to the flowers, nor ſo low as to ſcorch their leaves with the heat. At this time alſo, or a few days after, as you ſhall judge neceſſary, you ſhould cut ſome ſtiff paper, cards, or ſome ſuch thing, into collars about four inches over, and exactly round, cutting a hole in the middle of it about three fourths of an inch diameter, for the bottom of the flower to be let through; then place theſe collars about them, to ſupport the petals of the flower from hanging down; this collar ſhould be placed with inſide the calyx of the flower, and ſhould be ſupported thereby; then obſerve from day to day what progreſs your flowers make; and if one ſide comes out faſter than the other, you ſhould turn the pot about, and ſhift the other ſide towards the ſun; and alſo if the weather proves very hot, you ſhould ſhade the glaſſes in the heat of the day with Cabbage leaves, &c. to prevent their being ſcorched, or forced out too ſoon; and when the middle pod begins to riſe, you ſhould take out the calyx thereof with a pair of nippers made for that purpoſe; but this ſhould not be done too ſoon, leſt the middle part of the flower ſhould advance too high above the ſides, which will greatly diminiſh the beauty of it: and you ſhould alſo obſerve whether there are more leaves in the flower, than can properly be expanded for want of room; in which caſe you ſhould put out ſome of the lowermoſt or moſt unlikely leaves to ſpread, drawing out and expanding the others at the ſame time: and when your flowers are fully blown, if you cut them off, you ſhould put on a freſh collar of ſtiff paper, which ſhould be cut exactly to the ſize of the flower, that it may ſupport the petals to their full width, but not to be ſeen wider than the flower in any part: when this is put on, you muſt draw out the wideſt leaves to form the outſide of the flower, which although they ſhould be in the middle (as it often happens,) yet by removing the other leaves they may be drawn down, and ſo the next longeſt leaves upon them again, that the whole flower may appear equally globular without any hollow parts. In the doing of this, ſome floriſts are ſo curious as to render an indifferent flower very handſome; and on this depends, in a great meaſure, the ſkill of the artiſt to produce large fine flowers.

During the flowering ſeaſon, particular care ſhould be taken not to let them ſuffer for want of water, which ſhould by no means be raw ſpring water; nor do I approve of compound waters, ſuch as are enriched with various ſorts of dung; but the beſt and moſt natural water is that of a fine ſoft river; next to that is pond water, or ſtanding water; but if you have no other than ſpring water, it ſhould be expoſed to the ſun and air two days before it is uſed, otherwiſe it will give the flowers the canker and ſpoil them.

The directions here given are chiefly for the management of thoſe large Carnations, which require the greateſt ſkill of the floriſts, to have them in perfection; but as of late years theſe have not been ſo much in eſteem as formerly, and thoſe flowers which do not break their pods, and are termed whole Blowers, have now the preference. Theſe are generally planted in pots, and treated in the ſame way as the large flowers, but do not require ſo much trouble to blow them: all that is neceſſary to be done for theſe, is to faſten their ſtems up to flower-ſticks to prevent their being broken, and to take off the pods which proceed from the ſide of the ſtalks, leaving only the top bud to flower, if they are intended to be large and fair; and when the flowers begin to open, if they are ſcreened from the ſun in the heat of the day, and alſo from wet, they will continue much longer in beauty.

But although the moſt valuable of theſe flowers are uſually planted in pots, and thus carefully treated, yet many of theſe whole blowing flowers may be planted in beds, or borders of the flower-garden, where they are ſome of the principal ornaments during their continuance in flower, which is from the beginning of July till the middle of Auguſt, eſpecially if the ſeveral colours are properly intermixed; for the Flakes and Bizarrs ſhould be intermixed with the Picquettes, and not planted ſeparate, unleſs where they are deſigned for ſaving the ſeeds; in which caſe, thoſe which are the fineſt of each ſort, ſhould be planted in beds at a diſtance from each other, eſpecially where perſons are deſirous to keep them diſtinct; for, where the ſorts are blended together, there will be an admixture of their farina, ſo that the ſeeds will vary, and not produce the particular kinds; though I do not remember ever to have ſeen any Flake flowers ariſe from ſeeds of the Picquettes, nor vice verſâ.

The flowers which are planted in the full ground, generally produce ſeeds better than thoſe in pots; but whoever propoſes to raiſe a ſupply of new flowers from ſeeds, muſt always obſerve to ſave the beſt of their ſeedling flowers for this purpoſe; for it is well known, that after any of theſe flowers have been a few years propagated by layers, they become barren, and do not ſeed; which is alſo the caſe with moſt other plants which are propagated by ſlips, layers, or cuttings; ſo that the young plants which have been newly obtained from ſeeds, are always the moſt productive of ſeeds: the plants which are propagated by layers or ſlips, will always continue to produce the ſame flowers, ſo that when a fine variety is obtained, it is this way propagated and maintained; but all the new varieties come from ſeeds, ſo that all thoſe who are curious in theſe flowers, annually ſow their ſeeds.

I ſhall next proceed to the culture of that ſpecies, which is commonly known by the title of Sweet William; of this there are a great variety of different colours, which are ſingle, and three or four with double flowers: ſome of theſe have narrow leaves, which were formerly titled Sweet Johns, but of late that diſtinction has not been made, becauſe they are found to vary when raiſed from ſeeds.

Some of the ſingle flowers have very rich colours, which frequently vary in thoſe of the ſame bunch; there are others with fine variegated flowers, and others whoſe middles are of a ſoft red, bordered with white, which are called Painted Ladies; but where perſons are deſirous to preſerve any of theſe varieties in perfection, the beſt flowers of each ſhould be particularly marked, and no other permitted to ſtand near them, leſt their farina ſhould impregnate them, which would cauſe them to vary.

That which is called the Painted Lady Sweet William, is a very beautiful variety; the ſtalks of this do not riſe ſo high as moſt of the other; the bunches of flowers are larger, and produced more in the form of an umbel, the flowers ſtanding equal in height, make a better appearance: there are others whoſe ſtalks riſe three feet high, and the flowers of a very deep red or ſcarlet colour. Theſe all flower at the ſame time with the Carnations, which renders them leſs valuable, becauſe they have no ſcent.

The ſingle kinds of theſe flowers are generally propagated by ſeeds, which muſt be ſown the latter end of March or the beginning of April, in a bed of light earth, and in June they will be fit to tranſplant out; at which time you muſt prepare ſome beds ready for them, and ſet them at ſix inches diſtance every way: in theſe beds they may remain till Michaelmas, at which time they may be tranſplanted into the borders of the pleaſure-garden or wilderneſs. Theſe will flower the next year in June, and perfect their ſeeds in Auguſt, which you ſhould ſave from the beſt coloured flowers for a ſupply.

They may be alſo propagated by ſlipping their roots at Michaelmas; but this is ſeldom practiſed, ſince their ſeedling roots will always blow the ſtrongeſt, and new varieties are obtained yearly.

The four ſorts with double flowers are, 1. The broad-leaved ſort, which hath very double flowers, of a deep purple colour inclining to blue, which burſts its pods, ſo that it is not ſo much eſteemed as the others, and therefore has been leſs regarded, and is now almoſt totally baniſhed the gardens of the curious. 2. The Double Roſe Sweet William, whoſe flowers are of a fine deep Roſe colour, and ſmell ſweet; this is much valued for the beauty and ſweetneſs of its flowers; the empalement (or pods) of theſe flowers never burſt, ſo the flowers remain with their petals fully expanded, and do not hang down looſely as thoſe of the former. 3. The Mule, or Fairchild's Sweet William; it hath narrower leaves than either of the former, and is of that variety called Sweet John: this was ſaid to have been produced from ſeeds of a Carnation, which had been impregnated by the farina of the Sweet William; the flowers of this are of a brighter red colour than either of the former, their bunches are not quite ſo large, but the flowers have an agreeable odour. The fourth ſort has fine variegated flowers.

The double kinds are propagated by layers, as the Carnations; they love a middling ſoil, not too light, nor too heavy or ſtiff, nor too much dunged, which very often occaſions their rotting: theſe continue flowering for a long time, and are extremely beautiful, eſpecially the Mule, which produces two full blooms of flowers, one in June, and the other in July. This is very ſubject to canker and rot away, eſpecially if planted in a ſoil over wet or too dry, or if watered with ſharp ſpring water. Theſe flowers being planted in pots, are very proper to adorn court-yards at the time they are in flower.

The China Pink is generally ſuppoſed an annual plant, becauſe the plants which are raiſed from ſeeds flower and produce ripe ſeeds the ſame ſeaſon, ſo their roots are not often preſerved; but where they are planted on a dry ſoil, they will continue two years, and the ſecond year will produce a greater number of flowers than the firſt. There are a great variety of very rich colours in theſe flowers, which annually vary when raiſed from ſeeds. The double flowers of this ſort are moſt eſteemed, though the colours of the ſingle are more diſtinct and beautiful; for the multiplicity of petals in the double flowers, in a great meaſure, hides the deep ſhades, which are toward the lower part of the petals.

Theſe plants are propagated by ſeeds, which ſhould be ſown upon a gentle hot-bed about the beginning of April; this moderate heat is only intended to forward the vegetation of the ſeeds, therefore when the plants come up, they muſt have a large ſhare of air admitted to them, to prevent their drawing up weak; and as ſoon as the weather will permit, they muſt be expoſed to the open air; in about three weeks or a month after, the plants will be fit to remove; then they ſhould be carefully taken up with good roots, and planted in a bed of rich earth, at about three inches aſunder, being careful to ſhade them from the ſun till they have taken new root, and in dry weather they muſt have water three or four times a week. The farther care is to keep them clean from weeds till the end of May, at which time they may be tranſplanted to the places where they are deſigned to remain for flowering, when they may be taken up with large balls of earth to their roots, ſo as ſcarcely to feel their removal, eſpecially if it happens to rain at that time.

As theſe plants do not grow large, ſo when they are planted ſingly in the borders of the flower-garden, they do not make ſo fine an appearance, as where they are planted by themſelves in beds; or if they are planted in ſmall clumps, of ſix or eight roots in each, where the flowers being of different colours, ſet off each other to advantage.

Thoſe who are curious in theſe flowers, take particular care in ſaving their ſeeds, for they never permit any ſingle flowers to ſtand among their double, but pull them up as ſoon as they ſhew their flowers, and alſo draw out all thoſe which are not of lively good colours; where this is obſerved, the flowers may be kept in great perfection; but where perſons have truſty friends, who live at ſome diſtance, with whom they can exchange ſeeds once in two or three years, it is much better ſo to do, than to continue ſowing ſeeds in the ſame place many years in ſucceſſion, and this holds true in moſt ſorts of ſeeds: but the great difficulty is to meet with an honeſt perſon of equal ſkill, who will be as careful in the choice of his plants for ſeed, as if he was to ſow them himſelf.

DIAPENSIA. See Sanicula.

DICTAMNUS. Lin. Gen. Plant. 468. Fraxinella. Tourn. Inſt. R. H. 430. tab. 243. White Dittany, or Fraxinella; in French, *Fraxinelle.* This plant was titled Fraxinella, from Fraxinus the Aſh-tree, the leaves of this having ſome reſemblance in their form, to thoſe of the Aſh-tree, ſo it was called Little Aſh. But as this plant has been long mentioned under the title of Dictamnus albus, i. e. *White Dittany* in the diſpenſaries, ſo Dr. Linnæus has adapted that title to this genus.

The Characters are,

The empalement of the flower is compoſed of five ſmall oblong leaves, ending in points. The flower hath five oblong petals which are unequal, two of them turning upward, two are oblique on the ſides, and one turns downward. It hath ten riſing ſtamina, which are as long as the petals, which are ſituated between the two ſide petals; they are not equal in length, and are terminated by obtuſe four-cornered ſummits ſtanding erect. In the center is ſituated a five-cornered germen, ſupporting a ſhort incurved ſtyle, crowned by an acute ſtigma; the germen afterward becomes a capſule with five cells, each having a compreſſed margin, which ſpreads open at their exterior parts, but join together at their inner, opening with two valves, and incloſing ſeveral roundiſh, hard, ſhining ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, the flower having ten ſtamina and one ſtyle.

We have but one diſtinct Species of this genus, viz.

Dictamnus (*Albus*). Hort. Cliff. 161. Fraxinella. Cluſ. Hiſt. 99. and the Dictamnus albus, vulgò Fraxinella. C. B. P. 222. *White Dittany, commonly called Fraxinella.*

There are three varieties of this plant, one with a pale red flower ſtriped with purple, another with a white flower, and one with ſhorter ſpikes of flowers; but as I have obſerved them to vary when propagated by ſeeds, ſo I eſteem them only ſeminal varieties.

This is a very ornamental plant for gardens, and as it requires very little culture, ſo deſerves a place in all good gardens. It hath a perennial root, which ſtrikes deep into the ground, and the head annually increaſes in ſize; theſe ſend up many ſtalks, which riſe from two to three feet high, garniſhed with winged leaves placed alternate, compoſed of three or four pair of oblong lobes, terminated by an odd one: they are ſmooth and ſtiff, ſitting cloſe to the midrib, which hath a longitudinal furrow on the upper ſide; the lobes (or ſmall leaves) placed on each ſide the midrib, are oblique, but thoſe which terminate the leaf have their ſides equal. The flowers are produced in a long pyramidal looſe ſpike or thyrſe; on the top of the ſtalk, which is nine or ten inches long; the flowers of one ſort is white, and of the other they are of a pale red, marked with red or purple ſtripes. The whole plant when gently rubbed, emits an odour like that of Lemon peel, but when bruiſed has ſomething of a balſamic ſcent. It flowers the latter end of May, and in June, and the ſeeds ripen in September.

Theſe plants are propagated by ſeeds, which, if ſown in the autumn ſoon after they are ripe, the plants will appear the following April; but when they are kept out of the ground till the ſpring, the ſeeds ſeldom ſucceed; or if they do grow, it is the following ſpring before the plants appear, ſo that a whole year is loſt. When the plants come up, they muſt be conſtantly kept clean from weeds; and in the autumn when their leaves decay, the roots ſhould be carefully taken up, and planted in beds at ſix inches diſtance every way; theſe beds may be four feet broad, and the paths between them two, that there may be room enough to paſs between the beds to weed them. In theſe beds the plants may ſtand two years, during which time they muſt be conſtantly kept clean from weeds; and if they thrive well, they will be ſtrong enough to flower; ſo in the autumn they ſhould be carefully taken up, and planted in the middle of the borders of the flower-garden, where they will continue thirty or forty years, producing more ſtems of flowers in proportion to the ſize of the roots. All the culture theſe require, is to be kept clean from weeds, and the ground about them dug every winter.

The roots of this plant are uſed in medicine, and eſteemed cordial and cephalic, reſiſting putrefaction and poiſon, and are uſeful in malignant and peſtilential diſtempers, as alſo in epilepſies.

DICTAMNUS CRETICUS. See Origanum.

DIERVILLA. Tourn. Act. R. Par. 1706. Lonicera. Lin. Gen. Plant. 210.

The title of this genus was given it by Dr. Tournefort, after Mr. Dierville, a ſurgeon, who brought this plant from Acadia.

The Characters are,

The empalement of the flower is cut into five parts, almoſt to the bottom; the flower is of one leaf, having a tube at the bottom, but is cut into five parts at the top, and has the appearance of a lip flower; it hath five ſtamina, which are terminated by oblong ſummits, which are equal with the petal. At the bottom of the flower is ſituated an oval germen fixed to the empalement, ſupporting a ſlender ſtyle equal with the ſtamina, crowned by an obtuſe ſtigma; the germen afterward becomes a pyramidal berry, divided into four cells, which contain ſmall round ſeeds.

This genus of plants is ranged in the fourth ſection of Tournefort's third claſs, which includes the plants with a tubulous anomalous flower of one leaf. It is ranged by Dr. Linnæus under his genus of Lonicera, in the firſt ſection of his fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

We know but one Species of this genus at preſent, viz.

Diervilla (*Lonicera*) Acadienſis fruticoſa, flore luteo. Act. R. Par. 1706. *Shrubby Diervilla of Acadia with a yellow flower.* This is the Lonicera racemis terminalibus foliis ſerratis. Lin. Sp. Plant. 275. *Lonicera with bunches of flowers terminating the branches, and ſawed leaves.*

This plant grows naturally in the northern parts of America, from whence it was brought to Europe, and is now propagated in the gardens for ſale. It hath woody roots which ſpread far in the ground, and put out ſhoots at a diſtance from the principal ſtalk, whereby it multiplies greatly: the ſtalks are ligneous, and ſeldom riſe more than a foot and a half high; theſe are garniſhed with oblong heart-ſhaped leaves, ending in acute points; they are very ſlightly ſawed on their edges, and are placed oppoſite, ſitting cloſe to the ſtalks: the upper part of the ſtalks are garniſhed with flowers, which uſually come out from the ſide of the ſtalk at the ſitting on of the leaves, and alſo at the top of the ſtalks; there are two or three flowers ſuſtained upon each foot-ſtalk: they are of a pale yellow, and being ſmall, make no great appearance. Theſe come out in May, and if the ſeaſon proves moiſt and cold, they frequently flower again in Auguſt.

It is eaſily propagated by ſuckers, which it ſends out in plenty, and loves a moiſt ſoil and ſhady ſituation, where the cold will never injure it.

DIGITALIS. Lin. Gen. Plant. 676. Tourn. Inſt. R. H. 164. tab. 73. Raii Meth. Plant. 89. Foxglove; in French, *Digitale.*

The Characters are,

It hath a permanent empalement, which is cut into five parts; the flower is bell-ſhaped, of one petal, with a large open tube, whoſe baſe is cylindrical and contracted, but the brim is divided into four parts ſlightly; the upper lip ſpreading and indented at the top, the lower is larger. It hath four ſtamina, which are inſerted in the baſe of the petal, two being longer than the other, which are terminated by bipartite acuminated ſummits; the flower being paſt, the germen ſwells to an oval capſule, having two cells ſitting on the empalement, incloſing many ſmall angular ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, the flower having two long and two ſhorter ſtamina, and the ſeeds being included in a capſule.

The Species are,

1. Digitalis (*Purpurea*) calycinis foliolis ovatis acutis, corollis obtuſis, labio ſuperiore integro. Hort. Upſal. 178. *Foxglove whoſe ſmall leaves of the empalement are oval and acute, the petals obtuſe, and the upper lip entire.* Digitalis purpurea folio aſpero. C. B. P. 243. *Purple Foxglove with a rough leaf, or common Foxglove.*
2. Digitalis (*Thapſi*) foliis decurrentibus. Lin. Sp. 867. *Foxglove with running leaves.* Digitalis Hiſpanica purpurea minor. Tourn. Inſt. 165. *Leſſer Spaniſh purple Foxglove.*
3. Digitalis (*Lutea*) calycinis foliolis lanceolatis corollis acutis labio ſuperiore bifido. Hort. Upſal. 178. *Foxglove with ſpear-ſhaped leaves to the empalement, an acute petal, whoſe upper lip is bifid.* Digitalis minor lutea, parvo flore. C. B. P. 244. *Leſſer yellow Foxglove with a ſmall flower.*
4. Digitalis (*Magno flore*) foliolis calycinis linearibus, corollis acutis, labio ſuperiore integro, foliis lanceolatis. *Foxglove with long narrow leaves to the empalement, an acute petal, whoſe upper lip is entire, and ſpear-ſhaped leaves.* Digitalis lutea, magno flore. C. B. P. 244. *Yellow Foxglove with a larger flower.*
5. Digitalis (*Ferruginea*) calycinis foliolis ovatis obtuſis, corollæ labio inferiore longitudine floris. Lin. Sp. Plant. 622. *Foxglove with oval blunt leaves to the empalement, and the lower lip of the petal as long as the flower.* Digitalis anguſtifolia, flore ferrugineo. C. B. P. 244. *Narrow-leaved Foxglove with an iron-coloured flower.*
6. Digitalis (*Canarienſis*) calycinis foliolis lanceolatis, corollis bilabiatis acutis, caule fruticoſo. Lin. Sp. Plant. 622. *Foxglove with ſpear-ſhaped leaves to the empalement, an acute petal with two lips, and a ſhrubby ſtalk.* Digitalis acanthoides Canarienſis fruteſcens, flore aureo. Hort. Amſt. 2. p 105. *Shrubby Canary Foxglove like Bearſbreech, with a golden flower.*
7. Digitalis (*Orientalis*) calycinis foliolis acutis, foliis ovato-lanceolatis nervoſis. *Foxglove with acute leaves to the empalement, and oval, ſpear-ſhaped, veined leaves.* Digitalis lutea non ramoſa, ſcorzoneræ folio. Buxb. Cent. 25. *Yellow unbranched Foxglove with a leaf like Scorzonera.*

The firſt ſort grows naturally by the ſide of hedges in ſhady woods in moſt parts of England, ſo is rarely cultivated in gardens. This is a biennial plant, which the firſt year produces a great tuft of long rough leaves which are hairy; the ſecond year it ſhoots up a ſtrong herbaceous ſtalk, which riſes from three to four feet high, garniſhed with leaves of the ſame form as the lower, but they gradually leſſen upward, ſo thoſe which are intermixed with the flowers on the top are very narrow. The flowers grow in a long looſe thyrſe, ſtanding only on one ſide of the ſtalk; they are large, tubulous, and ſhaped like a thimble, of a purple colour, with ſeveral white ſpots on the under lip; theſe flowers are ſucceeded by oval capſules with two cells, which are filled with dark brown ſeeds. It flowers in June, and the ſeeds ripen in autumn; if they are permitted to ſcatter, the plants will come up in the ſpring, and become troubleſome weeds; but whoever has a mind to cultivate it, ſhould ſow the ſeeds in autumn, for thoſe which are ſown in the ſpring ſeldom ſucceed, or at leaſt lie one year in the ground before they grow. This plant ſtands in the liſt of medicinal ſimples of the diſpenſaries, and there is an ointment made of the flowers, and May-butter, which has been in good eſteem.

There is a variety of this with a white flower, which is found growing naturally in ſome parts of England, which differs from this only in the colour of the flower and leaves; but this difference is permanent, for I have cultivated it more than thirty years in the garden, and have never found it vary.

The ſecond ſort grows naturally in Spain, from whence I received the ſeeds; this plant ſeldom riſes much more than a foot and a half high; the lower leaves are ten inches long, and three broad in the middle; they are ſoft, woolly, and roughly veined on their under ſide; the ſtalks are garniſhed with leaves of the ſame ſhape, but ſmaller; the upper part of the ſtalk hath a ſhort thyrſe of purple flowers like thoſe of the common ſort, but they are ſmaller, and the ſegments of the petal are acute. This plant retains its difference when cultivated in gardens.

The third ſort hath very long obtuſe leaves near the root; the ſtalk is ſmall, and riſes from two to three feet high, the lower part being pretty cloſely garniſhed with ſmooth leaves, about three inches long and one broad, ending in obtuſe points: the upper part of the ſtalk, for ten inches in length, is adorned with ſmall yellow flowers, which are cloſely ranged on one ſide of the ſtalk, having a few very ſmall acute leaves placed between them, which are ſituated on the oppoſite ſide of the ſtalk; the upper lip of the flower is entire, and the petal is obtuſe. It flowers in June, and the ſeeds ripen in autumn.

The fourth ſort hath long ſmooth-veined leaves at the bottom; the ſtalk is ſtrong, and riſes two feet and a half high, garniſhed with leaves which are five inches long, one and a half broad, ending in acute points; theſe have many longitudinal veins, and are ſlightly ſawed on their edges; the upper part of the ſtalk is adorned with large yellow flowers, nearly of the ſize of thoſe of the common ſort, the brim having acute points, and the upper lip entire. This flowers and ripens its ſeeds about the ſame time as the former.

The fifth ſort hath narrow ſmooth leaves, which are entire; the ſtalk riſes near ſix feet high, and puts out ſome ſlender branches from the ſide toward the bottom; the lower part of the ſtalks is garniſhed with very narrow ſmall leaves, three inches long, and one third of an inch broad; the flowers terminate the ſtalk, growing in a very long ſpike, with very few leaves between them, and thoſe very ſmall; the empalement is divided into four obtuſe parts, the lower lip extending much longer than the upper. The flowers are of an iron colour, and appear in June.

The ſixth ſort grows naturally in the Canary Iſlands, from whence the ſeeds were firſt brought to England; and many of the plants were raiſed in the biſhop of London's gardens at Fulham, part of which were ſent to the royal gardens at Hampton Court, and ſome were ſent over to the gardens in Holland: thoſe which were ſent to Hampton Court, were preſerved there a few years, but by the ignorance of the gardeners, to whoſe care thoſe gardens were committed, this, with many other valuable plants, were ſoon deſtroyed.

This plant hath a ſhrubby ſtalk which riſes to the height of five or ſix feet, dividing into ſeveral branches, garniſhed with rough ſpear-ſhaped leaves, near five inches long, and two broad in the middle, gradually decreaſing to both ends, having a few ſhort ſerratures on their edges; theſe are placed alternately on the branches; each of theſe branches is terminated by a looſe ſpike of flowers, about four inches in length; the empalement of theſe is cut into five acute ſegments

ments almoſt to the bottom; the upper lip is long and entire, this is arched, and immediately under it the ſtamina and ſtyle are ſituated; the lower lip is obtuſe, and indented at the top; there are two acute ſegments on the ſide, which compoſe the chaps of the flower; there are two of the ſtamina longer than the other; theſe are crowned with roundiſh ſummits. In the bottom of the flower is ſituated the germen, ſupporting a ſlender ſtyle, crowned by an oval ſtigma; the germen afterward becomes an oval capſule, filled with ſmall angular ſeeds.

This plant begins to flower in May,and there is generally a ſucceſſion of flowers on the ſame plant, till the winter puts a ſtop to them, which renders the plant more valuable. It is propagated by ſeeds, which ſhould be ſown in pots filled with light earth, in the autumn, ſoon after the ſeeds are ripe; theſe pots ſhould be plunged into an old bed of tanners bark, whoſe heat is gone, and in mild weather the glaſſes ſhould be drawn off to admit the air; but in hard rains and froſt they muſt be kept on, to protect the ſeeds from both, which frequently deſtroys them here when they are expoſed; in the ſpring the plants will come up, when they ſhould enjoy the free air in mild weather, but muſt be protected from the cold. When theſe are large enough to tranſplant, they ſhould be each planted into a ſeparate ſmall pot filled with light earth, and placed under the frame till they have taken new root, then they ſhould be gradually inured to the open air. During the ſummer ſeaſon the plants ſhould remain abroad in a ſheltered ſituation, but in the winter they muſt be placed in a greenhouſe, for they will not live abroad in England; they muſt not be kept too warm and cloſe in the houſe, for they only want protection from the froſt; therefore in mild weather, they ſhould have free air conſtantly admitted to them, and they require frequent waterings, but they ſhould not have it in too great plenty in winter.

The ſeventh ſort grows naturally in Tartary, from whence the ſeeds were ſent to the imperial garden at Peterſburgh, and from thence I received them. This plant hath many oval ſpear-ſhaped leaves, which are ſmooth, ariſing from the root; between theſe ariſe the ſtalk, which grows about a foot high, and is garniſhed below with ſmooth ſpear-ſhaped leaves, from four to five inches long, and one and a half broad in the middle, leſſening gradually at both ends; theſe have no foot-ſtalks, but their baſe embraces the ſtalks half round; the upper part of the ſtalk is adorned by a ſhort looſe ſpike of yellow flowers, which are almoſt as large as thoſe of the great yellow ſort before-mentioned, but they are ſhorter. This flowers in May, and the ſeeds ripen in autumn.

All theſe ſorts ſhould be ſown in the autumn; for if the ſeeds are ſown in the ſpring, they commonly fail, or at leaſt lie a whole year in the ground before they vegetate. The plants are biennial (except the ſeventh ſort) and generally periſh ſoon after the ſeeds are ripe.

DIOSCOREA. Plum. Nov. Gen. 9. tab. 26. Lin. Gen. Plant. 995.

The Characters are,

It hath male and female flowers in different plants; the male flowers have a bell-ſhaped perianthium of one leaf, cut into ſix parts, but have no petals or empalement; they have ſix ſhort hairy ſtamina, terminated by ſingle ſummits. The female flowers have the ſame perianthium as the male; they have no petals, but have a ſmall three-cornered germen, ſupporting three ſtyles, which are crowned by ſingle ſtigmas; the perianthium afterward becomes a triangular capſule with three cells, opening with three valves, containing two compreſſed bordered ſeeds in each.

This genus of plants is ranged in the ſixth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Hexandria. The plants of this claſs and ſection have male and female flowers on different plants, and the male flowers have ſix ſtamina.

The Species are,

1. Dioscorea (*Sativa*) foliis cordatis alternis, caule lævi tereti. Hort. Cliff. 459. *Dioſcorea with heart-ſhaped leaves placed alternate, and a ſmooth taper ſtalk.* Dioſcorea ſcandens, foliis tamni fructu racemoſo. Plum. Nov. Gen. 9. *Climbing Dioſcorea with black Briony leaves, and fruit growing in long bunches.*
2. Dioscorea (*Haſtata*) foliis haſtato-cordatis, caule lævi, racemis longiſſimis. *Dioſcorea with ſpear-pointed heart-ſhaped leaves, a ſmooth ſtalk, and very long bunches of flowers.* Dioſcorea ſcandens, folio haſtato fructu racemoſo. Houſt. MSS. *Climbing Dioſcorea with a ſpear-pointed leaf, and fruit growing in bunches.*
3. Dioscorea (*Villoſa*) foliis cordatis alternis, oppoſitiſque caule lævi. Lin. Sp. 1463. *Dioſcorea with heart-ſhaped leaves placed alternate and oppoſite, and a ſmooth ſtalk.* Dioſcorea ſcandens, folio ſubrotundo acuminato fructu racemoſo. Houſt. MSS. *Climbing Dioſcorea with a roundiſh pointed leaf, and fruit growing in long bunches.*
4. Dioscorea (*Bulbifera*) foliis cordatis, caule lævi bulbifera. Flor. Zeyl. 360. *Dioſcorea with heart-ſhaped leaves, and a ſmooth ſtalk bearing bulbs.* Volubilis nigra, radice albâ aut purpureâ maxima tuberoſa eſculenta, caule membranulis extantibus alato, folio cordato nervoſo. Sloan. Cat. Jam. 46. *The Yam, or Yammes.*
5. Dioscorea (*Oppoſitifolia*) foliis oppoſitis ovatis acuminatis. Lin. Sp. 1483. *Dioſcorea with oval-pointed leaves growing oppoſite.*
6. Dioscorea (*Digitata*) foliis digitatis. Hort. Cliff. 459. *Dioſcorea with hand-ſhaped leaves.* Nureni Kelengu. Hort. Mal. 7. p. 67.

The firſt ſort grows naturally in moſt of the iſlands in the Weſt Indies. I received the ſeeds of this ſort from Jamaica, where the late Dr. Houſtoun found it growing plentifully. This hath ſlender climbing ſtalks, which fix themſelves to any ſupport near them, and riſe to the height of eighteen or twenty feet, garniſhed with heart-ſhaped leaves, ending with acute points, having five longitudinal veins, which ariſe from the foot-ſtalks, which diverge toward the ſides, but meet again at the point of the leaves. They ſtand upon pretty long foot-ſtalks, from the baſe of which ariſe the branching ſpikes of flowers, which are ſmall, and have no beauty; the female flowers are ſucceeded by three-cornered oblong capſules, having three cells, each containing two compreſſed ſeeds.

The ſecond ſort differs from the firſt in the ſhape of their leaves, theſe having two round ears at their baſe, but the middle extends to an acute point, like that of an halbert. The bunches of flowers are longer, and are looſer placed than thoſe of the former ſort.

The third ſort hath broad, round, heart-ſhaped leaves, which end in acute points; theſe have many longitudinal veins which ariſe from the foot-ſtalk, and diverge to the ſide, but afterward join at the point of the leaf; the flowers come out on long looſe ſtrings, ſtanding on ſhort foot-ſtalks; the female flowers are ſucceeded by three-cornered oblong capſules, with three cells, having compreſſed bordered ſeeds.

The fourth ſort hath triangular winged ſtalks, which trail upon the ground and extend to a great length; theſe frequently put out roots from the joints as they lie upon the ground, whereby the plants are multiplied. The roots of this plant are eaten in many parts of both Indies, where the plants are much cultivated.

The fifth ſort grows naturally in Virginia, and in other parts of North America. This hath a ſmooth ſtalk which climbs on the neighbouring plants, and riſes five or ſix feet high, garniſhed with heart-ſhaped leaves, which are placed oppoſite; they are covered with ſmall hairs, and have ſeveral longitudinal veins. The flowers come out from the ſide of the ſtalk in the ſame manner as the other ſorts, but have no beauty. Theſe plants are preſerved in ſome curious botanic gardens for the ſake of variety; but as they have no beauty, there are few perſons who will allow them a place, eſpecially as moſt of the ſorts require a good ſtove to preſerve them through the winter in England.

Theſe plants may be propagated by laying their branches into the ground, which in about three months will put out roots, and may then be taken from the old plants, and planted into ſeparate pots, which ſhould be plunged into the tan-bed in the ſtove; during the winter theſe plants ſhould have but little water given them; but in ſummer, when they are growing vigorouſly, they ſhould be watered three or four times a week, and in warm weather the glaſſes ſhould be opened to admit a large ſhare of free air. Theſe plants rarely flower in England, but when the ſeeds are ſent from America, they ſhould be immediately ſown in pots, and plunged into a hot-bed, where, if the ſeeds are ſown early in the ſpring, the plants will come up the ſame ſeaſon; but when they are ſown late, the ſeeds often remain in the ground till the following ſpring before they vegetate; therefore when the plants do not come up the firſt ſeaſon, the pots ſhould be ſcreened from the froſt the following winter, and put into a new hot-bed in the ſpring, which will bring up the plants, if the ſeeds were good.

The fourth ſort is much cultivated by the inhabitants of the iſlands in America, and is of great uſe to them for feeding of their negroes; and the white people make puddings of their roots, when ground to a ſort of flour. This plant is ſuppoſed to have been brought from the Eaſt to the Weſt Indies, for it has not been diſcovered to grow wild in any part of America; but in the iſland of Ceylon, and on the coaſt of Malabar, it grows in the woods, and there are in thoſe places a great variety of ſorts.

This ſort, which is chiefly cultivated in the Weſt Indies, has a root as big as a man's leg, of an irregular form, and of a dirty brown colour on the outſide, but when cut, are white and meally within. The ſtalks of this plant are triangular and winged; the leaves are heart-ſhaped, having two ears, ſomewhat like thoſe of Arum. Theſe ſtalks climb to the height of ten or twelve feet, when they grow near trees or ſhrubs, to which they faſten themſelves, otherwiſe they trail upon the ground.

This plant is propagated by cutting of the root into pieces, obſerving to preſerve an eye or bud to each, as is practiſed in planting of Potatoes; each of theſe being planted will grow, and produce three or four large roots. In America they are commonly ſix or eight months in the ground before the roots are taken up for uſe. The roots are roaſted or boiled, and eaten by the inhabitants, and ſometimes are made into bread.

In ſome curious gardens this plant is preſerved for the ſake of variety, but it is ſo tender as not to live in England, unleſs it is placed in a warm ſtove. As theſe roots are frequently brought from America, whoever hath an inclination to preſerve the plant, may cut them in the manner before deſcribed, and plant each piece in a pot filled with freſh earth, and plunged into a hot-bed of tanners bark, and give them little water until they ſhoot, leſt they ſhould rot. With this management I have had the ſhoots ten feet high, but the roots have not grown to any great ſize with me. This plant will not thrive in the open air in the warmeſt time of the year, ſo muſt conſtantly be kept in the bark-ſtove.

DIOSMA. Lin. Gen. Plant. 241. Spiræa. Com. Rar. Plant. 2. African Spiræa, vulgò.

The CHARACTERS are,

The flower hath a permanent empalement, which is divided into four acute ſegments, which are plain at their baſe; it hath five obtuſe petals, which ſpread open and are as long as the empalement; it hath five ſtamina terminated by oval erect ſummits, and a five-pointed hollow nectarium ſitting on the germen, from which ariſes a ſingle ſtyle, crowned by an obſolete ſtigma. The germen afterward becomes a fruit compoſed of five compreſſed capſules, which open lengthways, each incloſing one ſmooth oblong ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flowers having five ſtamina and one ſtyle.

The SPECIES are,

1. DIOSMA (*Oppoſitifolius*) foliis ſubulatis acutis oppoſitis. Hort. Cliff. 71. *Dioſma with acute awl-ſhaped leaves placed oppoſite.* Spiræa Africana, foliis cruciatim poſitis. Com. Rar. Plant. 1. tab. 1. *African Spiræa with leaves placed in form of a croſs.*
2. DIOSMA (*Hirſuta*) foliis linearibus hirſutis. Hort. Cliff. 71. *Dioſma with narrow hairy leaves.* Spiræa Africana odorata, foliis piloſis. Com. Rar. Plant. 3. tab. 3. *Sweet African Spiræa with hairy leaves.*
3. DIOSMA (*Rubra*) foliis linearibus acutis glabris, carinatis ſubtus bifarium punctatis. Lin. Sp. Plant. 198. *Dioſma with ſmooth, narrow, acute leaves, which are ſpotted on their under ſide.* Spiræa Africana odorato, floribus ſuaverubentibus. Com. Rar. Plant. 2. *Sweet African Spiræa with ſoft red flowers.*
4. DIOSMA (*Erricoides*) foliis lineari-lanceolatis ſubtus convexis, bifariam imbricatis. Lin. Sp. Plant. 198. *Dioſma with narrow ſpear-ſhaped leaves, which are convex on their under ſide, and imbricated two ways.* Spiræa Africana ericæ bacciferæ foliis. Raii Hiſt. 91. *African Spiræa with leaves like the Berry-bearing Heath.*
5. DIOSMA (*Lanceolata*) foliis lanceolatis glabris. Lin. Sp. 287. *Dioſma with ſmooth ſpear-ſhaped leaves.* Spiræa Africana, Saturejæ foliis brevioribus. Raii Dendr. 91.

The firſt ſort riſes to the height of three feet; the branches are very long and ſlender, and are produced from the ſtem very irregularly; the leaves are placed croſſways, and are pointed; theſe are every evening cloſed up to the branches. The flowers are produced along the branches from between the leaves; and in the evening, when theſe flowers are expanded, and the leaves are cloſely embracing the ſtalks, the whole plant appears as if covered with ſpikes of white flowers; and as theſe plants continue a long time in flower, they make a fine appearance when the plants are intermixed with other exotics in the open air.

The ſecond ſort has been long known under the title of Spiræa Africana odorata, foliis piloſis, or *Sweet-ſcented African Spiræa, with hairy leaves.* This ſort makes a very handſome ſhrub, growing to the height of five or ſix feet; the ſtalks are woody, ſending out many ſlender branches; the leaves come out alternately on every ſide, which are narrow-pointed and hairy. The flowers are produced in ſmall cluſters at the end of the ſhoots, which are white; theſe are ſucceeded by ſtarry ſeed-veſſels, having five corners, like thoſe of the ſtarry Aniſe; each of theſe corners is a cell, having one ſmooth, ſhining, oblong, black ſeed; theſe ſeed-veſſels abound with a reſin, which affords a grateful ſcent, as doth alſo the whole plant.

The third ſort is of humbler growth than either of the former, ſeldom riſing above three feet high, and ſpreads out into many branches; the leaves of this ſort are ſmooth, and reſemble thoſe of the Heath, and this plant from thence had the name of Erica Æthiopica, &c. given it by Dr. Plukenet: the flowers of this kind are produced in cluſters at the end of the branches, like thoſe of the ſecond ſort, but are ſmaller, and the bunches are not ſo large.

All theſe plants are propagated by cuttings, which may be planted during any of the ſummer months, in pots filled with light freſh earth, and plunged into a very moderate hot-bed, where they ſhould be ſhaded in the day time from the ſun, and frequently refreſhed with water. In about two months the cuttings will have taken root, when they ſhould be each tranſplanted into a ſmall pot, and placed in a ſhady ſituation until the plants have taken freſh root, when they may be placed among other exotic plants, in a ſheltered ſituation: theſe plants may remain abroad until the beginning of October or later, if the ſeaſon continues favourable; for they only require to be ſheltered from froſt, ſo that in a dry airy green-houſe they may be preſerved very well in winter, and in ſummer they may be expoſed to the open air with other green-houſe plants.

Theſe plants grow naturally at the Cape of Good Hope, from whence the ſeeds were ſent to Europe, where ſome of the ſpecies have been long preſerved in the gardens of the curious. There have been ſome other ſpecies in the Engliſh gardens than are here enumerated, but theſe are all that are at preſent to be found here.

The ſecond ſort frequently ripens its ſeeds in England; but if the ſeeds are not ſown ſoon after they are ripe, they rarely grow, or they commonly lie a whole year in the ground.

DIOSPYROS. Lin. Gen. Plant. 1027. Guaiacana. Tourn. Inſt. R. H. 600. tab. 371. The Indian Date Plumb.

The Characters are,

It hath hermaphrodite and female flowers on the ſame plant, and male flowers on ſeparate plants; the hermaphrodite flowers have a large obtuſe permanent empalement of one leaf, which is divided into four parts; the flower hath one petal which is ſhaped like a pitcher, and cut at the brim into four ſegments, which ſpread open; it hath eight ſhort briſtly ſtamina firmly joined to the empalement, terminated by oblong ſummits which have no farina. In the center is ſituated a roundiſh germen, ſupporting a ſingle quadrifid ſtyle, crowned by an obtuſe bifid ſtigma; the germen afterward becomes a large globular berry with many cells, each including one oblong, compreſſed, hard ſeed. The male flowers have a one-leaved empalement, cut into ſmall acute ſegments; the petal is thick and four-cornered, cut into four obtuſe ſegments which turn backward; they have eight ſhort ſtamina, terminated by long, acute, twin ſummits, but have no germen.

This genus of plants is ranged in the ſecond ſection of Linnæus's twenty-third claſs, intitled Polygamia Diœcia. The plants of this claſs and ſection have hermaphrodite and female flowers growing on the ſame plant, and the male on ſeparate plants.

The Species are,

1. Diospyros (*Lotus*) foliorum paginis diſcoloribus. Lin. Sp. Plant. 1057. *Dioſpyros with the ſurface of the leaves of two colours.* Guaiacana. J. B. 2. 138. *The Indian Date Plumb.*
2. Diospyros (*Virginiana*) foliorum paginis concoloribus. Lin. Sp. Plant. 1057. *Dioſpyros with the ſurface of the leaves of one colour.* Guaiacana Virginiana Piſhamin dicta. Boerh. Ind. alt. 2. *The Piſhamin or Perſimon, and by ſome Pitchumon Plumb.*

The firſt ſort is ſuppoſed to be a native of Africa, and was tranſplanted from thence into ſeveral parts of Italy, and alſo the ſouth of France. The fruit of this tree is by ſome ſuppoſed to be the Lotus, which Ulyſſes and his companions were inchanted with. This is a tree of a middling growth in the warm parts of Europe, where there are ſeveral of them which are upward of thirty feet high; but particularly in the botanic garden at Padua there is one very old tree, which has been deſcribed by ſome of the former botaniſts, under the title of Guaicum Patavinum. This tree produces plenty of fruit every year, from the ſeeds of which many plants have been raiſed. In England there are none of theſe trees, but what have been raiſed within a few years paſt, in the phyſic garden at Chelſea; for the ſeeds of which I was greatly obliged to my much honoured friend, his excellency the Chevalier Rathgeb, his imperial majeſty's miniſter at Venice, who has alſo ſupplied me with many other curious plants, trees, and fruits, from different parts of the world, where his extenſive correſpondence has been employed to collect whatever rare plants he could procure; and his generoſity in communicating what ſeeds and plants he can procure to the phyſic garden at Chelſea, requires this public acknowledgment.

The ſecond ſort is a native of America, but particularly in Virginia and Carolina there is great plenty of theſe trees growing in the woods. The ſeeds of this ſort are frequently brought to England, where the trees are now become pretty common in the nurſeries about London. This riſes to the height of fourteen or ſixteen feet, but generally divides into many irregular trunks near the ground, ſo that it is very rare to ſee a handſome tree of this ſort. This produces plenty of fruit in England, but they never come to perfection here. In America the inhabitants preſerve the fruit until it be rotten (as is practiſed by Medlars in England) when they are eſteemed a pleaſant fruit.

Theſe are both propagated by ſeeds, which will come up very well in the open ground; but if they are ſown upon a moderate hot-bed, the plants will come up much ſooner, and make a greater progreſs; but in this caſe the ſeeds ſhould be ſown in pots or boxes of earth, and plunged into the hot-bed, becauſe the plants will not bear tranſplanting till autumn, when the leaves fall off; ſo that when the plants are up, and have made ſome progreſs, they may be inured by degrees to the open air; and in June they may be wholly expoſed, and may remain abroad until November, when it will be proper to ſet the pots under a hot-bed frame to protect them from hard froſt, which, while they are very young, may kill the tops of the plants; but they muſt have as much free air as poſſible in mild weather. The following ſpring, before the plants begin to ſhoot, they ſhould be tranſplanted into a nurſery, in a warm ſituation, where they may be trained up for two years, and then removed to the places where they are deſigned to remain. Theſe are both hardy enough to reſiſt the greateſt cold of this country, after the plants have acquired ſtrength.

DIPSACUS. Lin. Gen. Plant. 107. Tourn. Inſt. R. H. 466. tab. 265. [διψακὸς, *Gr.* i. e. thirſty. It is ſaid to have taken its name by way of contrary, becauſe it receives the dew or rain in the hollow ſinus of its leaves that cohere together, by which it drives away the injuries of thirſt. It is alſo called Labrum Veneris, from the poſition of its leaves, which form a ſort of baſon, containing a liquor that beautifies the face.] The Teazel; in French, *Chardon à Bonnitier.*

The Characters are,

It hath many florets collected in one common perianthium, which is permanent; the florets have but one petal, which is tubular, cut into four parts at the top, which are erect. They have four hairy ſtamina which are as long as the petal, terminated by proſtrate ſummits; the germen is ſituated below the flower, ſupporting a ſlender ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a column-ſhaped ſeed, incloſed in the common conical fruit, which is divided by long prickly partitions.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flower having four ſtamina and one ſtyle.

The Species are,

1. Dipsacus (*Sylveſtris*) foliis ſeſſilibus ſerratis, ariſtis fructibus erectis. *Teazel with ſawed leaves ſet cloſe to the ſtalks, and erect beards to the fruit.* Dipſacus ſylveſtris. Dod. Pemp. 735. *Wild Teazel.*
2. Dipsacus (*Fullonum*) foliis connatis, ariſtis fructibus recurvis. *Teazel with leaves joined at their baſe, and the beards of the fruit recurved.* Dipſacus ſativus. Dod. Pemp. 735. *Cultivated Teazel.*
3. Dipsacus (*Laciniatus*) foliis connatis ſinuatis. Lin. Sp. Plant. 97. *Teazel with ſinuated leaves joined at their baſe.* Dipſacus folio laciniato. C. B. P. 385. *Teazel with a laciniated leaf.*
4. Dipsacus (*Piloſus*) foliis petiolatis appendiculatis. Hort. Upſal. 25. *Teazel with foot-ſtalks having appendices.* Dipſacus ſylveſtris, capitulo minore, ſeu. Virga Paſtoris minor. C. B. P. 385. *Wild Teazel with a ſmaller head, or ſmaller Shepherd's Rod.*

The firſt of theſe plants is very common upon dry banks in moſt parts of England, and is ſeldom cultivated in gardens, unleſs for the ſake of variety.

The fourth ſort grows naturally in many places near London, and is rarely admitted into gardens.

The third ſort grows naturally in Alſace, and is kept in botanic gardens for the ſake of variety; this differs from the wild Teazel in having the leaves deeply cut and jagged.

But it is the ſecond ſort only which is cultivated for uſe, which is called Carduus Fullorum, or Fullonum, being of ſo ſingular uſe in raiſing the knap upon woollen cloth, for which purpoſe there are great quantities of this plant cultivated in the weſt country. This plant is propagated by ſowing the ſeeds in March, upon a ſoil that has been well ploughed: about one peck of this ſeed will ſow an acre; for the plants ſhould have room to grow, otherwiſe the heads will not be ſo large, nor in ſo great quantity. When the plants are come up, you muſt hoe them in the ſame manner as is practiſed for Turneps, cutting down all the weeds, and ſingling out the plants to about ſix or eight inches diſtance; and as the plants advance, and the weeds begin to grow again, you muſt hoe them a ſecond time, cutting out the plants to a wider diſtance, for they ſhould be, at laſt, left at leaſt a foot aſunder: and you ſhould be particularly careful to clear them from weeds, eſpecially the firſt ſummer; for when the plants have ſpread ſo as to cover the ſurface of the ground, the weeds will not ſo readily grow between them. The ſecond year after ſowing, the plants will ſhoot up ſtalks with heads, which will be fit to cut about the beginning of Auguſt; at which time they ſhould be cut, and tied up in bunches, ſetting them in the ſun if the weather be fair; but if not, they muſt be ſet in rooms to dry. The common produce is about an hundred and ſixty bundles or ſtaves upon an acre, which they ſell for about one ſhilling a ſtave. Some people ſow Caraway and other ſeeds among their Teazels, but this is not a good method, for the one ſpoils the other; nor can you ſo eaſily clear them from weeds, as when alone. Dr. Linnæus ſuppoſes this to be only a ſeminal variety of the common wild Teazel; but I have cultivated both the ſorts more than forty years, and have never found either of them alter, ſo that there can be no doubt of their being diſtinct ſpecies.

DIRCA, Leather Wood.

The Characters are,

There is no empalement to the flower, which is club-ſhaped, of one petal, having a ſhort-bellied tube, and an unequal border; it hath eight ſlender ſtamina ſituated in the middle of the tube, terminated by erect roundiſh ſummits, with an oval germen, ſupporting a ſlender ſtyle which is longer than the ſtamina, crowned by a ſimple ſtigma. The germen afterward becomes a berry with one cell, incloſing one ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's eighth claſs, intitled Octandria Monogynia, the flower having eight ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Dirca (*Paluſtris*). Amœn. Acad. 3. p. 12. *Marſh Leatherwood.* Thymelæa floribus albis primo vere erumpentibus, foliis oblongis acuminatis, viminibus & cortice valde tenacibus. Flor. Virg. 155.

This ſhrub grows naturally in ſwamps in Virginia, Canada, and other parts of North America, where it ſeldom riſes more than five or ſix feet high, but in Europe it rarely is more than half ſo high; it ſends out many articulated branches near the root, garniſhed with oval leaves, of a pale yellowiſh colour, and ſmooth; the flowers come out from the ſide of the branches, two or three upon each foot-ſtalk; they are of a greeniſh white colour, and appear early in the ſpring, juſt at the time when the leaves begin to ſhoot; the flowers are ſeldom ſucceeded by ſeeds in England. This ſhrub is very difficult to propagate in Europe; for as it does not produce ſeeds here, it can only be increaſed by layers or cuttings, and theſe are generally two years before they put out roots; for as the ſhrubs grow naturally in very moiſt places, they are with difficulty preſerved in gardens, unleſs they are planted in wet ground, but they are ſeldom injured by cold.

DITTANY, the white. See Dictamnus.

DITTANY of Crete. See Origanum.

DOCK. See Lapathum.

DODARTIA. Lin. Gen. Plant. 698. Tourn. Cor. 47. tab. 478. [This plant was ſo named by Dr. Tournefort, from Monſieur Dodart, a member of the Academy of Sciences at Paris.] We have no Engliſh name for this plant.

The Characters are,

The flower hath a permanent empalement of one leaf, which is bell-ſhaped, cut into five parts at top; the flower hath one petal, is ringent, having a cylindrical diflexed tube much longer than the empalement; the upper lip riſes and is indented, the lower lip ſpreads open and is trifid, the middle ſegment being narrow. It hath four ſtamina which incline to the upper lip, two of which are ſhorter than the other, and are terminated by ſmall roundiſh ſummits. In the center is ſituated a round germen, ſupporting an awl-ſhaped ſtyle, crowned by a bifid obtuſe ſtigma. The germen afterward becomes a globular capſule with two cells, filled with ſmall ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, the flower having two long and two ſhort ſtamina, and the ſeeds being included in a capſule.

The Species are,

1. Dodartia (*Orientalis*) foliis linearibus integerrimis glabris. Lin. Sp. Plant. 633. *Dodartia with very narrow, ſmooth, entire leaves.* Dodartia Orientalis, flore purpuraſcente. Tourn. Cor. 47. *Eaſtern Dodartia with a purpliſh flower.*
2. Dodartia (*Linaria*) foliis radicalibus oblongo-ovatis, ſerratis, caulinis linearibus integerrimis floribus ſpicatis terminalibus. *Dodartia with oblong, oval, ſawed leaves at the bottom, thoſe on the ſtalks narrow and entire, and flowers growing in ſpikes at the end of the ſtalks.* Linaria bellidis folio. C. B. P. 212. *Toad Flax with a Daiſy leaf.*

The firſt ſort was diſcovered by Dr. Tournefort near mount Ararat in Armenia, from whence he ſent the ſeeds to the royal garden at Paris, where they ſucceeded, and from thence moſt of the curious gardens in Europe have been ſupplied with this plant. This plant having characters which are different from all thoſe of Tournefort's Inſtitutions, he conſtituted this genus, and gave it the title from Monſieur Dodart, member of the Royal Academy of Sciences at Paris, and phyſician to her Royal Highneſs the Princeſs of Conti.

It hath a perennial root which creeps far under the ſurface, and ſends out new ſtalks at a great diſtance from the parent plant; theſe ſtalks are firm, a little compreſſed, and grow a foot and a half high, ſending out ſeveral ſide branches, garniſhed with long, fleſhy, narrow leaves placed oppoſite, of a deep green colour; thoſe on the lower part of the ſtalk are ſhorter and broader than thoſe above, but thoſe on the upper part of the ſtalk are entire; and at theſe joints the flowers come out ſingly on each ſide the ſtalk, ſitting cloſe to it; theſe are near an inch long; the bottom is tubulous, but divides into two lips above; the upper lip is hollow like a ſpoon, the convex ſide ſtanding upward, and is divided into two parts; the lower lip is divided into three parts, the middle being the narroweſt. The flower is of a deep purple colour, and appears in July, and is rarely ſucceeded by ſeeds in England. It propagates very faſt by its creeping roots, ſo that when it is once eſtabliſhed in a garden, it will multiply faſt enough; it loves a light dry ſoil, and may be tranſplanted either in autumn when the ſtalks decay, or in the ſpring before the new ſtalks ariſe.

The ſecond ſort is a biennial, or at moſt a triennial plant, which frequently periſhes ſoon after the ſeeds are ripe. This ſends out from the root ſeveral oblong leaves, which are near four inches long, narrow at their baſe, but increaſe in width upward, where they are about an inch broad, rounded at the end, and deeply ſawed on the edges; between theſe ariſe the ſtalks, which grow a foot high, their lower parts being garniſhed with leaves of the ſame form as the lower leaves, but much ſmaller; the upper leaves are very narrow and entire. The flowers grow in ſpikes on the top of the ſtalks; they are very ſmall and white, but are ſhaped like thoſe of the former ſort. This is propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe, upon a border of light earth, where they are deſigned to remain. When the plants appear the following ſpring, they muſt be thinned, and kept clear from weeds, which is all the culture they require: the ſecond year they will flower and ſeed, after which the plants uſually decay; when the ſeeds are ſown in the ſpring, the plants never come up the ſame year.

DODECATHEON. See Meadia.

DOG's TOOTH. See Erythronium.

DOG-WOOD. See Cornus.

DOLICHOS, Kidney Bean.

The Characters are,

The empalement is of one leaf, ſhort, and cut into four equal ſegments. The flower is of the butterfly kind, having a large round vexillum which is reflexed. The wings are oval, obtuſe, and the length of the keel. The keel is moon-ſhaped, compreſſed, and the top aſcends; it hath nine ſtamina joined below, and a ſingle one ſtanding ſeparate, terminated by ſingle ſummits, with a linear compreſſed germen, ſupporting an aſcending ſtyle, crowned by a bearded ſtigma. The germen afterward becomes a large oblong pod with two valves, containing compreſſed elliptical ſeeds.

This genus is diſtinguiſhed from Phaſeolus, by the keel of the flower not being ſpiral.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, the flower having ten ſtamina in two bodies.

The Species are,

1. Dolichos (*Lablab*) volubilis, leguminibus ovato-acinaciformibus, ſeminibus ovatis hilo arcuato verſus alteram extremitatem. Prod. Leyd. 368. *Dolichos with a winding ſtalk, oval bill-ſhaped pods, and oval ſeeds.* Phaſeolus Ægyptiacus nigro ſemine. C. B. P. 341.
2. Dolichos (*Uncinatus*) volubilis, pedunculis multifloris leguminibus cylindricis hirſutis apice unguiculo ſubulato hamato, caule hirto. Lin. Sp. 1019. *Dolichos with a winding ſtalk, many flowers on each foot-ſtalk, cylindrical hairy pods, whoſe points are crooked and awl-ſhaped.*
3. Dolichos (*Pruriens*) volubilis, leguminibus racemoſis hirtis, valvulis ſubcarinatis, pedunculis ternis. Jacq. Amer. 27. *Dolichos with a winding ſtalk, hairy pods growing in a racemus, almoſt boat-ſhaped valves, and each foot-ſtalk having three pods.*
4. Dolichos (*Urens*) volubilis, leguminibus racemoſis hirtis tranſverſim lamellatis, ſeminibus hilo cinctis. Jacq. Amer. 27. *Dolichos with a winding ſtalk, hairy pods in a racemus, whoſe hairs are ſituated in tranſverſe lamellæ, commonly called Cow-itch.*

There are many other ſpecies of this genus, as there are alſo of Phaſeolus; but as there are few of them cultivated in the Engliſh gardens, it would ſwell this work to a great bulk, if they were all inſerted which have come to our knowledge, as the author has cultivated more than ſixty ſpecies, beſide many varieties.

The two firſt ſorts here mentioned, are cultivated in warm countries for the table, but in England theſe ſeldom perfect their ſeeds; and were they to thrive here as well as in the warm countries, they would be little eſteemed, becauſe we have much better ſorts in our gardens already; for the ſcarlet flowering Kidney Bean is preferable to all the other ſorts for eating, ſo deſerves our care to cultivate it more than any other.

The third and fourth ſorts are ſometimes preſerved in botanic gardens, but eſpecially the fourth, whoſe pods are cloſely covered with ſtinging hairs, commonly known by the title of Cow-itch; but theſe are too tender to thrive in the open air in this country, ſo that whoever is deſirous to have the plants, ſhould ſow their ſeeds in a hot-bed in March; and when the plants are come up, they ſhould be each planted in a ſeparate pot, and plunged into the hot-bed again, being careful to ſhade them till they have taken root; after which they muſt have freſh air every day admitted to them, in proportion to the warmth of the ſeaſon; and when the plants are too tall to remain in the hot-bed, they ſhould be removed into the bark-ſtove, where, if they are allowed room to run, they will flower and perfect their ſeeds.

DORIA. See Solidago and Othonna.

DORONICUM. Lin. Gen. Plant. 862. Tourn. Inſt. R. H. 487. tab. 477. Leopard's Bane.

The Characters are,

It hath a flower compoſed of ſeveral hermaphrodite florets, which are ſituated in the center, and form the diſk, and of female florets which compoſe the rays; theſe are included in one common empalement, which hath a double ſeries of leaves as long as the rays. The hermaphrodite florets are funnel-ſhaped, and cut into five parts at the top; theſe have five ſhort hairy ſtamina, terminated by cylindrical ſummits. In the bottom is ſituated the germen, ſupporting a ſlender ſtyle, crowned by an indented ſtigma; the germen afterward becomes a ſingle, oval, compreſſed ſeed, crowned with hairy down. The female florets are formed like a tongue, which are ſpread out and compoſe the border; theſe have a germen, ſupporting a ſtyle, crowned by two reflexed ſtigmas, but have no ſtamina; the germen becomes a ſingle furrowed ſeed, covered with a hairy down.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia ſuperflua. The plants of this ſection have female and hermaphrodite flowers, which are both fruitful.

The Species are,

1. Doronicum (*Pardalianches*) foliis cordatis obtuſis, denticulatis radicalibus petiolatis, caulinis amplexicaulibus. Lin. Mat. Med. 394. *Leopard's Bane with obtuſe, heart-ſhaped, indented leaves, thoſe from the root having foot-ſtalks, and thoſe above embracing the ſtalks.* Doronicum maximum, foliis caulem amplexiantibus. C. B. P. 184. *Greateſt Leopard's Bane with leaves embracing the ſtalks.*
2. Doronicum (*Plantagineum*) foliis ovatis acutis, ſubdentatis, ramis alternis. Hort. Cliff. 411. *Leopard's Bane with oval-pointed leaves indented at bottom, and alternate branches.* Doronicum plantaginis folio. C. B. P. 184. *Leopard's Bane with a Plantain leaf.*
3. Doronicum (*Helveticum*) foliis lanceolatis, denticulatis, ſubtus tomentoſis, caule unifloro. Prod. Leyd. 160. *Leopard's Bane with ſpear-ſhaped indented leaves, woolly on their under ſide, and one flower on a ſtalk.* Doronicum Helveticum incanum. C. B. P. 185. *Hoary Helvetian Leopard's Bane.*
4. Doronicum (*Bellidiaſtrum*) caule nudo ſimpliciſſimo unifloro. Hort. Cliff. 500. *Leopard's Bane with a naked ſingle ſtalk having one flower.* Bellis ſylveſtris media caule carens. C. B. P. 261. *Middle wild Daiſy having a tall ſtalk.*

The firſt ſort grows naturally in Hungary, and upon the Helvetian mountains, but is frequently preſerved in the Engliſh gardens. It hath thick fleſhy roots, which are divided into many knots or knees, ſending out ſtrong fleſhy fibres, which penetrate deep into the ground; and from theſe ariſe in the ſpring a cluſter of heart-ſhaped leaves, which are hairy, and ſtand upon foot-ſtalks; between theſe ariſe the flower-ſtalks, which are channelled and hairy, growing near three feet high, putting out one or two ſmaller ſtalks from the ſide, which grow erect, and are garniſhed with one or two heart-ſhaped leaves, cloſely embracing the ſtalks with their baſe; each ſtalk is terminated by one large yellow flower, compoſed of about twenty-four rays or female florets, which are about an inch long, plain, and indented in three parts at the top. In the center is ſituated a great number of hermaphrodite florets, which compoſe the diſk; theſe are tubulous, and ſlightly cut at the top into five parts. The flowers appear in May, and are ſucceeded by ſeeds which ripen in July; theſe are crowned by a hairy down, which ſerves to convey them to a diſtance.

This plant multiplies very faſt by its ſpreading roots, and if the ſeeds are permitted to ſcatter, they will produce plants wherever they happen to fall, ſo that it becomes a weed where it is once eſtabliſhed; it loves a moiſt ſoil and a ſhady ſituation.

The ſecond ſort hath oval leaves, ending in acute points; theſe are indented on their edges toward their baſe, but their upper parts are entire; the ſtalks riſe about two feet high; each is terminated by a large yellow flower, like thoſe of the former ſort; the ſtalks of this ſort have two or three leaves, which are placed alternately, and their baſe ſits cloſe to the ſtalks; theſe are not ſo hairy as thoſe of the former ſort; it flowers about the ſame time with that, and the ſeeds ripen well in England. This grows naturally in Portugal, Spain, and Italy, but is equally hardy with the firſt, and multiplies in as great plenty; the root is perennial.

The third ſort hath longer leaves than either of the former, which are covered with a hoary down on their under ſide, and are indented on their edges; the ſtalks are ſingle, and have ſeldom more than one leaf upon each; theſe grow a foot and a half high, and are terminated by a ſingle flower on the top, like thoſe of the former ſorts. This grows naturally on the Pyrenees and Helvetian mountains. It delights in a moiſt ſoil and a ſhady ſituation, and propagates in plenty, either from ſeeds or by parting the roots: it flowers and ſeeds about the ſame time with the former.

The fourth ſort grows naturally on the Alps and Pyrenean mountains; this hath a perennial root; the leaves are like of the leſſer Daiſy, but longer, and not ſo broad. The flower grows upon a naked foot-ſtalk, which is near a foot long; the roots ſeldom ſend out more than one ſtalk; the rays of the flower are white, and very like thoſe of the common Daiſy; the diſk of the flower is yellow, which is compoſed of hermaphrodite flowers.

This plant is preſerved in botanic gardens for the ſake of variety, but the flowers make little better appearance than thoſe of the common Field Daiſy, only they ſtand upon much taller foot-ſtalks. It muſt have a ſhady ſituation and a moiſt ſoil, otherwiſe it will not thrive in this country; it is propagated by parting of the roots, for the ſeeds do not ripen well in England. I received this from Verona, near which place it grows naturally.

The roots of the firſt ſort have been ſometimes uſed in medicine, ſome having commended it as an expeller of the poiſon of ſcorpions; but others reckon it to be a poiſon, and affirm that it will deſtroy wolves and dogs.

The other ſorts which have been formerly ranged under this genus, are now ſeparated, and may be found under the title ARNICA.

DORSIFEROUS plants [of dorſum, the back, and fero, *Lat.* to bear,] ſuch plants as are of the capillary kind, without ſtalk, and that bear their ſeeds on the backſide of their leaves.

DORSTENIA. Plum. Nov. Gen. 29. tab. 8. Lin. Gen. Plant. 147. [This plant was ſo named by father Plumier, from Dr. Dorſten, a German phyſician, who publiſhed a hiſtory of plants in folio.] Contrayerva.

The CHARACTERS are,

It hath one common plain involucrum ſituated vertically, upon which ſit many ſmall florets as in a diſk; theſe have no petals, but have four ſhort ſlender ſtamina, terminated by roundiſh ſummits. In the center is ſituated a roundiſh germen, ſupporting a ſingle ſtyle crowned by an obtuſe ſtigma; the germen afterward becomes a ſingle ſeed, incloſed in the common fleſhy receptacle.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flower having four ſtamina and one ſtyle.

The SPECIES are,

1. DORSTENIA (*Contrayerva*) acaulis, foliis pinnatifido-palmatis, ſerratis, floribus quadrangulis. Lin. Sp. 176. *Dwarf Dorſtenia with many pointed, hand-ſhaped, ſawed leaves, and flowers placed on a quadrangular receptacle.* Dorſtenia ſphondylii folio, dentariæ radice. Plum. Nov. Gen. 29. *Dorſtenia with a Cow Parſnep leaf, and a Toothwort root.*
2. DORSTENIA (*Houſtoni*) acaulis, foliis cordatis angulatis acuminatis, floribus quadrangulis. Lin. Sp. 176. *Dwarf Dorſtenia with angular, heart-ſhaped, pointed leaves, and quadrangular receptacles to the flowers.* Dorſtenia dentariæ radice, folio minùs laciniato, placentâ quadrangulari & undulatâ. Houſt. MSS. *Contrayerva with a Toothwort root, a leaf leſs cut, and a quadrangular waved placenta.*
3. DORSTENIA (*Drakena*) acaulis, foliis pinnatifido-palmatis integerrimis, floribus ovalibus. Lin. Sp. 176. *Dwarf Dorſtenia with many pointed, hand-ſhaped, entire leaves, and an oval receptacle to the flowers; handed leaves, whoſe angles are very acute, and an oblong four-cornered placenta.*

The firſt of theſe plants was diſcovered by my late ingenious friend Dr. William Houſtoun, near Old Vera Cruz in New Spain. The ſecond was found by the ſame gentleman, on the rocky grounds about Campeachy. The third ſort was found in great plenty in the iſland of Tobago, by Mr. Robert Millar, ſurgeon. But the roots of all theſe ſpecies are indifferently brought over, and uſed in medicine, and for dyeing.

The firſt ſort ſends out ſeveral leaves from the root, which are about four inches long, and as much in breadth; theſe are deeply laciniated into five or ſeven obtuſe parts, ſtanding upon foot-ſtalks near four inches long; they are ſmooth, and of a deep green. The ſtalk which ſupports the placenta ariſes from the root, and grows near four inches high, upon which the fleſhy placenta is vertically placed; this is of an oval form about one inch long, and three quarters broad. Upon the upper ſurface of this, the ſmall flowers are cloſely ſituated, the fleſhy part becoming an involucrum to them; theſe are very ſmall, and ſcarce conſpicuous at a diſtance, being of an herbaceous colour.

The ſecond ſort ſends out ſeveral angular heart-ſhaped leaves from the root, which have foot-ſtalks eight or nine inches in length and very ſlender; the leaves are about three inches and a half long, and almoſt four broad at their baſe, the two ears having two or three angles which are acute, and the middle of the leaves are extended and end in acute points like a halbert; theſe are ſmooth and of a lucid green; the foot-ſtalk which ſuſtains the placenta is nine inches long, and about half an inch ſquare, and the upper ſurface cloſely ſet with ſmall flowers like the firſt.

The third ſort ſends out leaves of different forms; ſome of the lower leaves are heart-ſhaped, having a few indentures on their edges, and ending in acute points, but the larger leaves are deeply cut like the fingers on a hand, into ſix or ſeven acute ſegments. Theſe leaves are five inches long, and ſix broad in the middle; they are of a deep green, and ſtand upon long foot-ſtalks. The placenta is very thick and fleſhy, an inch and a half long, and three quarters broad, having four acute corners; theſe have a number of ſmall flowers, placed on their upper ſurface like the other ſpecies.

Theſe plants are at preſent very rare in Europe, nor was it known what the plant was, whoſe roots were imported, and had been long uſed in medicine in England, until the late Dr. Houſtoun informed us: for although father Plumier had diſcovered one ſpecies of this plant, and given the name of Dorſtenia to the genus, yet he ſeems not to have known, that the Contrayerva was the root of that plant.

It will be difficult to obtain theſe plants, becauſe the ſeeds are ſeldom to be found good; nor will they grow, if they are kept long out of the ground; ſo that the only ſure method to obtain them is, to have the roots taken up at the time when their leaves begin to decay, and planted pretty cloſe in boxes of earth, which may be brought very ſafe to England, provided they are preſerved from ſalt water, and are not over-watered with freſh water in their paſſage. When the plants arrive, they ſhould be tranſplanted each into a ſeparate pot filled with freſh earth, and plunged into the bark-ſtove, which ſhould be kept of a moderate heat; and the plants muſt be frequently refreſhed with water during the ſummer ſeaſon; but in winter, when the leaves are decayed, it ſhould be given to them more ſparingly. With this management theſe plants may not only be maintained, but may alſo be increaſed by parting their roots in the ſpring, before the plants put out their leaves.

DORYCNIUM. See Lotus.

DOUGLASSIA. See Volkameria.

DRABA. Dillen. Gen. Lin. Gen. Plant. 714. Alyſſon. Tourn. Inſt. R. H. 216. tab. 104.

The Characters are,

The flower hath a four-leaved empalement, which falls off. It hath four petals placed in form of a croſs. It hath ſix ſtamina, four of which are as long as the empalement, the other two are much ſhorter and incurved; theſe are terminated by roundiſh ſummits. In the center is ſituated a bifid germen, ſupporting a permanent ſtyle, crowned by an oblong ſtigma. The germen afterward becomes a very ſhort capſule with two cells, ſeparated by the ſwelling ſtyle, which is oblique, and longer than the capſule. The valves are parallel to the middle, and divide the lower part of the cell from the upper, which is open, round, concave, and opens oblique, each cell containing a ſingle ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifteenth claſs, intitled Tetradynamia Siliculoſa, the flower having four long and two ſhort ſtamina, and the ſeeds growing in ſhort capſules or pods.

The Species are,

1. Draba (*Alpina*) ſcapo nudo ſimplici, foliis lanceolatis integerrimis. Fl. Lapp. 255. *Draba with a ſingle naked ſtalk, and very entire ſpear-ſhaped leaves.* Alyſſon Alpinum, hirſutum luteum. Tourn. Inſt. 217. *Yellow hairy Alpine Madwort.*
2. Draba (*Verna*) ſcapis nudis, foliis lanceolatis ſub inciſis. Hort. Cliff. 333. *Draba with naked ſtalks and cut leaves.* Alyſſon vulgare, polygoni folio, caule nudo. Tourn. Inſt. 217. *Common Madwort with a Knot-graſs leaf and naked ſtalk.*
3. Draba (*Pyrenaica*) ſcapo nudo, foliis cuneiformibus trilobis. Lœfl. Lin. Sp. Plant. 642. *Draba with a naked ſtalk, and wedge-ſhaped leaves with three lobes.* This is the Alyſſon Pyrenaicum, perenne, minium, foliis trifidis. Tourn. Inſt. 217. *Leaſt perennial Madwort of the Pyrenees with trifid leaves.*
4. Draba (*Muralis*) caule ramoſo, foliis cordatis dentatis amplexicaulibus. Prod. Leyd. 33. *Draba with a branching ſtalk, and heart-ſhaped indented leaves embracing the ſtalks.* Alyſſon veronicæ folio. Tourn. Inſt. 217. *Madwort with a Speedwell leaf.*
5. Draba (*Polygonifolia*) caule ramoſo, foliis ovatis ſeſſilibus dentatis. Lin. Sp. Plant. 643. *Draba with a branching ſtalk, and oval indented leaves growing cloſe to the branches.* Alyſſon Alpinum, polygoni folio incano. Tourn. Inſt. R. H. 217. *Alpine Madwort with a hoary Knot-graſs leaf.*
6. Draba (*Incana*) foliis caulinis numeroſis incanis, ſiliculis oblongis. Flor. Suec. 526. *Draba with many hoary leaves on the ſtalks, and oblique pods.* Lunaria ſiliqua oblongâ intortâ. Tourn. Inſt. 219. *Moonwort with an oblong intorted pod.*

The firſt ſort grows naturally on the Alps, and other mountainous parts of Europe; this is a very low plant, which divides into ſmall heads like ſome ſorts of Houſeleek, and from thence it was titled Sedum Alpinum &c. or Alpine Houſeleek. The leaves are ſhort, narrow, and very hairy; from each of theſe heads come out a naked flower-ſtalk an inch and a half high, terminated by looſe ſpikes of yellow flowers, having four obtuſe petals placed in form of a croſs; when they fade they are ſucceeded by triangular or heart-ſhaped pods, which are compreſſed, and incloſe three or four roundiſh ſeeds. It flowers in March, and the ſeeds ripen the beginning of June.

This plant is eaſily propagated by parting of the heads; the beſt time for doing of this is in autumn, becauſe it ſhoots up to flower very early in the ſpring. It ſhould have a moiſt ſoil and a ſhady ſituation, where it will thrive and flower annually. It requires no other culture but to keep it clean from weeds.

The ſecond ſort is an annual plant, which grows naturally upon walls and dry banks in many parts of England, ſo is never cultivated in gardens. This flowers in April, and the ſeeds ripen in May.

The third ſort grows naturally on the Alps, and other mountainous parts of Europe. This is a low perennial plant, which ſeldom riſes more than two inches high; it has a ſhrubby ſtalk, which divides into many ſmall heads like the firſt ſort. The leaves are ſmall, ſome of them are winged, having five ſhort narrow lobes, placed on a midrib, others have but three. The flowers come out in cluſters, ſitting cloſe to the leaves. They are of a bright purple colour, and appear early in the ſpring. This is a perennial plant, which may be propagated by parting of the heads in the ſame manner as the firſt, and requires the ſame treatment.

The fourth ſort grows naturally in ſhady woods in many parts of Europe, and is but ſeldom kept in gardens, unleſs for the ſake of variety. It is an annual plant, riſing with an upright branching ſtalk about ten inches high, garniſhed with heart-ſhaped indented leaves, which embrace the ſtalks with their baſe. The ſtalks are terminated by looſe ſpikes of white flowers, which appear the beginning of May; in June the ſeeds ripen, and the plants ſoon after decay. If the ſeeds are permitted to ſcatter, the plants will come up without trouble. It muſt have a ſhady ſituation, and delights in a moiſt ſoil.

The fifth ſort is an annual plant, which grows in ſhady woods in the northern parts of Europe. This is like the former ſort, but the leaves are larger, rounder, and do not embrace the ſtalks; they are alſo hairy, and the flowers are yellow. If the ſeeds of this are permitted to ſcatter, the plants will maintain themſelves if they have a ſhady ſituation.

The ſixth ſort riſes with an upright ſtalk about a foot high, the lower part being very cloſely garniſhed by oblong hoary leaves, which are indented on their edges. The upper part of the ſtalks puts out two or three ſhort branches; theſe are almoſt naked of leaves, as is alſo the upper part of the ſtalk. The flowers come out looſely on the top of the ſtalk; they are compoſed of four ſmall white petals placed in form of a croſs, which are ſucceeded by oblong pods, which are twiſted, containing three or four roundiſh compreſſed ſeeds. It flowers in June, and the ſeeds ripen in July. This grows naturally in the north of England and in Wales.

This plant ſeldom continues more than two years, but if the ſeeds are ſown in autumn in a ſhady border, the plants will come up in the ſpring; or where the ſeeds are permitted to ſcatter, the plants will riſe without any trouble.

DRACO ARBOR. See Palma.

DRACO HERBA. [i. e. Dragon's-wort.] Tarragon, vulgò. See Abrotanum.

DRACOCEPHALUM. Lin. Gen. Plant. 648. Dracocephalon. Tourn. Inſt. R. H. 181. tab. 83. [of δράκων, a dragon, and κεφαλὴ, a head.] i. e. Dragon's-Head.

The Characters are,

The flower hath a ſhort permanent empalement of one leaf, which is tubulous. It hath one ringent petal, with a tube the length of the empalement, with large oblong inflated chaps. The upper lip is obtuſe and arched, the under lip is trifid; the two ſide ſegments are erect, the middle turns downward and is indented. It hath four ſtamina ſituated near the upper lip, two being ſhorter than the other, and are terminated by heart-ſhaped ſummits. It hath a four-parted germen, ſupporting a ſlender ſtyle, ſituated with the ſtamina, and crowned by a bifid reflexed ſtigma. The germen afterward becomes four oval oblong ſeeds, incloſed in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, the flower having two long and two ſhorter ſtamina, and the ſeeds are naked.

The Species are,

1. Dracocephalum (*Virginianum*) floribus ſpicatis foliis lanceolatis ſerratis. Lin. Sp. 828. *American Dragon's-Head with ſingle leaves and ſpiked flowers.* Dracocephalon Americanum. Breyn. Prod. 1. 34. *American Dragon's-Head.*

6. **Dracocephalum** (*Nutans*) floribus verticillatis, bracteis oblongis ovatis integerrimis, corollis majuſculis nutantibus. Hort. Upſal. 167. *Dragon's-Head with flowers growing in whorls, the ſmall leaves under the flowers are oblong, entire, and hanging flowers much larger than the empalement.* Moldavica betonicæ folio, floribus minoribus cæruleis pendulis. Amman. Ruth. 44. *Moldavian Balm with a Betony leaf, and ſmaller blue pendulous flowers.*

7. **Dracocephalum** (*Thymiflorum*) floribus verticillatis, bracteis oblongis integerrimis, corollis vix calyce majoribus. Hort. Upſal. 167. *Dragon's-Head with flowers growing in whorls, the ſmall leaves are oblong, entire, and the flowers equal with the empalement.* Moldavica betonicæ folio, floribus minimis pallidè cæruleis. Amman. Ruth. 46. *Moldavian Balm with a Betony leaf, and very ſmall blue flowers.*

8. **Dracocephalum** (*Peltatum*) floribus verticillatis, bracteis orbiculatis ſerratociliatis. Hort. Upſal. 166. *Dragon's-Head with flowers growing in whorls, oval bracteæ and very narrow ſpear-ſhaped leaves.* Moldavica orientalis, ſalicis folio, flore parvo cæruleo. Tourn. Cor. 11. *Eaſtern Moldavian Balm with a Willow leaf, and a ſmall blue flower.*

9. **Dracocephalum** (*Grandiflorum*) floribus verticillatis foliis ovatis inciſo-crenatis, bracteis lanceolatis integerrimis. Lin. Sp. Plant. 595. *Dragon's-Head with flowers growing in whorls, oval leaves which are cut and crenated, and ſpear-ſhaped bracteæ which are entire.*

The firſt ſort is a native of North America, where it grows in the woods, and by the ſides of rivers. This riſes with an upright ſtalk, which is four-cornered, near three feet high, garniſhed with ſpear-ſhaped leaves about three inches long, and half an inch broad, ſitting cloſe to the ſtalk; they are ſawed on their edges, and are placed oppoſite at each joint, ſometimes there are three leaves ſtanding round at the ſame place. The flowers are purple and grow in ſpikes on the top of the ſtalks, ſo make a pretty variety among other hardy plants, eſpecially if the plants are ſtrong and vigorous. This is a perennial plant, which will live in the open air, but requires a moiſt ſoil, or ſhould be duly watered in dry weather, otherwiſe the leaves will ſhrink, and the flowers will make little appearance. This may be allowed a place in the ſhady borders of a garden, ſince it will not ramble, or take up much room. It flowers in July, and continues until the middle or end of Auguſt, and may be propagated by parting of the roots in autumn.

The ſecond ſort is a native of the Canary Iſlands, and hath been long an inhabitant in the gardens; it is uſually called by the gardeners Balm of Gilead, from the ſtrong reſinous ſcent which the leaves emit on being rubbed. This is a perennial plant, which riſes with ſeveral ſquare ſtalks to the height of three feet or more, becoming ligneous at their lower parts, and are garniſhed with compound leaves at each joint, which are placed oppoſite; theſe have three or five lobes, which are oblong, pointed, and ſawed on their edges. The flowers come out in ſhort thick ſpikes on the top of the ſtalks; they are of a pale blue colour, and are ſucceeded by ſeeds, which ripen very well in England. This plant continues producing flowers moſt part of ſummer; it is uſually kept in green-houſes; but in mild winters the plants will live abroad, if they are planted in warm borders; and thoſe plants which are kept in pots, will thrive much better when they are ſheltered under a frame, than if placed in a green-houſe, where the plants are apt to draw up weak, for they ſhould have as much free air as poſſible in mild weather, and only require to be ſheltered from ſevere froſt. This may be propagated by ſeeds, which, if ſown in autumn, will more certainly grow, than thoſe which are ſown in the ſpring; but if theſe are ſown in pots, they muſt be ſheltered under a frame in the winter, and if the plants do not come up the ſame autumn, they will ariſe in the ſpring; but if the ſeeds are ſown in the full ground, it ſhould be in a warm border; and in hard froſt they ſhould be ſheltered, otherwiſe the young plants will be deſtroyed. The plants may alſo be propagated by cuttings; which, if planted in a ſhady border any time in ſummer, will very ſoon take root, and furniſh plenty of rooted plants.

The third ſort is a native of Moldavia; this has been long preſerved in curious gardens. It is an annual plant, which riſes with branching ſtalks a foot and a half high, garniſhed with oblong leaves, which are placed oppoſite, and are deeply ſawed on their edges. The flowers come out in whorls round the ſtalks at every joint; theſe are blue, and appear in July, continuing to the middle of Auguſt, and the ſeeds ripen in September. The plants have a ſtrong balſamic odour, which is to ſome perſons very agreeable: the ſeeds ſhould be ſown in ſmall patches in the ſpring, upon the borders where they are to remain, and when the plants come up, they ſhould be thinned where they grow too near together, and kept clear from weeds, which is the only culture they require. Of this there is a variety with white flowers, which is pretty common in the gardens; this only differs from the other in the colour of the flowers, but yet theſe conſtantly retain their difference from ſeeds.

The fourth ſort was diſcovered by Dr. Tournefort in the Archipelago, who ſent the ſeeds to the royal garden at Paris, which have ſince been communicated to many curious gardens in Europe; this riſes with upright ſtalks about a foot high, which ſeldom put out branches; theſe are garniſhed with long narrow leaves, which are entire, placed oppoſite at each joint, where the flowers come out in whorls, almoſt the whole length of the ſtalks; theſe are of a pale blue, and appear about the ſame time as the former; this ſort has very ſmall flowers, which make no great appearance, therefore is ſeldom cultivated, except in botanic gardens for the ſake of variety.

The fifth ſort was diſcovered by Dr. Tournefort in the Levant; this hath hoary ſquare ſtalks, which riſe a foot and a half high, putting out two or three ſide branches, garniſhed with hoary leaves near two inches long, and half an inch broad, a little indented on their edges; they are placed oppoſite at the joints, juſt under the whorls of flowers, which ſit cloſe to the ſtalk; theſe are larger than thoſe of the other ſpecies, and are of a fine blue colour, which between the hoary leaves of the plant, make a pretty appearance. It flowers and ſeeds about the ſame time as the former ſorts; this is generally treated as an annual plant, like the former ſorts, but the roots of this will live two years if they are in a dry ſoil. There is a variety of this with white flowers, the ſeeds of which generally produce the ſame coloured flowers.

The ſixth ſort grows naturally in Siberia, from whence the ſeeds were ſent to the imperial garden at Peterſburgh, and the late Dr. Amman, who was profeſſor of botany, ſent me the ſeeds. This is an annual plant, from whoſe roots come out many ſquare weak ſtalks, which grow about nine inches long; theſe are at the bottom garniſhed with oval ſpear-ſhaped leaves about two inches long, and one inch and a quarter broad, ſtanding oppoſite upon pretty long foot-ſtalks, and are crenated on their edges. The upper part of the ſtalks have ſmaller leaves, which ſit cloſe at the joints, from whence come out the flowers in whorls; they are of a deep blue colour, and hang downward; theſe appear at the ſame time with the former, and the ſeeds ripen in autumn.

The ſeventh ſort grows alſo in Siberia, the ſeeds of this were ſent me with the former. It hath ſquare ſtalks, which riſe a foot and a half high; the lower leaves are very like thoſe of Betony, and ſtand upon very long foot-ſtalks. The upper leaves are ſmall, and ſit cloſer to the ſtalks. The flowers come out in whorls at every joint; theſe are very ſmall, and of a pale purple or blue colour, ſo make little appearance, but it is preſerved in ſome gardens for the ſake of variety.

The eighth ſort grows naturally in the Levant, from whence Dr. Tournefort ſent the ſeeds to the royal garden at Paris. This is an annual plant, which riſes with a ſquare ſtalk about a foot high, ſending out two ſmall ſide branches from the lower part. The leaves are ſpear-ſhaped, and crenated on their edges; they are placed oppoſite, and ſtand on foot-ſtalks. The flowers are ſmall, of a purpliſh colour, and come out in whorls round the ſtalks, having two roundiſh-ſmall leaves (called bracteæ) immediately under them, which are ſawed on their edges, each ſerrature ending with a long hair. This ſort flowers and ſeeds at the ſame time as the former.

All theſe ſorts are propagated by ſeeds, which may be ſown either in the ſpring or autumn, in the places where the plants are to remain, and will require no other treatment than the third ſort.

DRACONTIUM. Lin. Gen. Plant. 916. Dracunculus. Tourn. Inſt. R. H. 160. tab. 70. Dragon; in French, *Serpentaire*.

The Characters are,

It hath a ſingle cylindrical ſpadix (or ſtalk) on the upper part of which the parts of fructification are diſpoſed in a ſingular manner. The flowers have no empalement, but have five oval concave petals, which are equal; they have ſeven narrow depreſſed ſtamina the length of the petals, terminated by oblong, four-cornered, twin ſummits, which ſtand erect; they have an oval germen, ſupporting a taper ſtyle, crowned by a three-cornered ſtigma. The germen afterward becomes a roundiſh berry, incloſing ſeveral ſeeds; theſe are all incloſed in a large fleſhy ſpatha (or ſheath) opening with one valve.

This genus of plants is ranged in the ſeventh ſection of Linnæus's twentieth claſs, intitled Gynandria Polyandria. This claſs and ſection contains the plants which have male and female flowers joined in the ſame ſpike, and the male flowers have ſeveral ſtamina.

The Species are,

1. Dracontium (*Pertuſum*) foliis pertuſis, caule ſcandente. Lin. Sp. Plant. 968. *Dragon with leaves having holes, and a climbing ſtalk.* Arum hederaceum, amplis foliis perforatis. Plum. Amer. 40. tab. 56. *Climbing Arum with large perforated leaves.*
2. Dracontium (*Polyphyllum*) ſcapo breviſſimo, petiolo radicato, lacero, foliolis tripartitis, laciniis pinnatifidis. Hort. Cliff. 434. *Dragon with a very ſhort ſtalk, the foot-ſtalk cut, and the ſmall leaves divided into three parts, which terminate in many points.* Arum polyphyllum, caule ſcabro punicante. Par. Bat. 93. *Many leaved Arum with a rough purple ſtalk.*
3. Dracontium (*Spinoſum*) foliis ſagittatis, pedunculis petioliſque aculeatis. Flor. Zeyl. 328. *Dragon with arrow-pointed leaves, whoſe foot-ſtalks have ſpines.* Arum Zeylanicum ſpinoſum, ſagittæ foliis. Par. Bat. 75. *Prickly Arum of Ceylon with arrow-pointed leaves.*
4. Dracontium (*Camtſchatcenſe*) foliis lanceolatis. Amœn. Acad. 2. p. 360. *Dragon with ſpear-ſhaped leaves.*

The firſt ſort grows naturally in moſt of the iſlands in the Weſt-Indies. This hath ſlender jointed ſtalks, which put out roots at every joint, that faſten to the trunks of trees, walls, or any ſupport which is near them, and thereby riſe to the height of twenty-five or thirty feet. The leaves are placed alternately, ſtanding upon long foot-ſtalks; they are four or five inches long, and two and a half broad, having ſeveral oblong holes in each, which on the firſt view appears as if eaten by inſects, but they are natural to the leaves. The flowers are produced at the top of the ſtalk, which always ſwells to a larger ſize in that part than in any other; theſe are covered with an oblong ſpatha (or hood) of a whitiſh green colour, which opens longitudinally on one ſide, and ſhews the piſtil, which is cloſely covered with flowers, of a pale yellow, inclining to white. When this plant begins to flower, it ſeldom advances farther in height, ſo that theſe ſeldom are more than ſeven or eight feet high; but the leaves are much larger on theſe, than thoſe of the plants which ramble much farther.

This plant is eaſily propagated by cuttings, which, if planted in pots filled with poor ſandy earth, and plunged into a hot-bed, will ſoon put out roots, if they had none before; but there are few of the joints which have not roots: the plants are tender, ſo will not live in the open air in England, therefore the pots ſhould be placed near the walls of the hot-houſe, againſt which the plants will climb, and faſten their roots into the wall, and thereby ſupport the ſtalks. They ſhould have but little water given them in the winter, but in warm weather it muſt be given them three or four times a week, and in the ſummer the free air ſhould be admitted to them in plenty. The plants have no particular ſeaſon of flowering, for they ſometimes flower in autumn, and at other times in the ſpring, but they do not ripen their ſeeds in England.

The ſecond ſort grows naturally in ſeveral of the iſlands of America. I received roots of this from Barbuda. This hath a large knobbed irregular root, covered with a rugged brown ſkin. The ſtalk riſes about a foot high, is naked to the top, where it is garniſhed with a tuft of leaves, which are divided into many parts. The ſtalk is ſmooth, of a purple colour, but is full of ſharp protuberances of different colours, which ſhine like the body of a ſerpent. The ſpadix (or ſtalk) of the flower riſes immediately from the root, and is ſeldom more than three inches high, having an oblong ſwelling hood at the top, which opens lengthways, ſhewing the ſhort, thick, pointed piſtil within, upon which the flowers are cloſely ranged.

This ſort is tender, ſo requires a warm ſtove to preſerve it in England. The roots muſt be planted in pots filled with light kitchen-garden earth, and plunged into the tan-bed in the ſtove, where they ſhould conſtantly remain; in the winter they muſt be watered very ſparingly, but in warm weather, when the plants are in vigour, they muſt be often refreſhed, but it ſhould not be given them in too great quantities; with this management the plants will flower, but their roots do not increaſe here.

The third ſort grows naturally in the iſland of Ceylon, and in ſeveral parts of India; this hath an oblong thick root, full of joints, from which ariſe ſeveral leaves, ſhaped like thoſe of the common Arum, but their foot-ſtalks are covered with rough protuberances. The ſtalk which ſupports the flower is ſhort, and ſet with the like protuberances; and at the top is a hood, or ſpatha, about four inches long, as thick as a man's finger, which opens longitudinally, and expoſes the piſtil, which is ſet with flowers. This is a tender plant, and requires the ſame treatment as the former ſort.

The fourth ſort hath roots like the common Arum, from which come out ſeveral ſpear-ſhaped leaves, ſtanding each upon a ſeparate foot-ſtalk, ariſing immediately from the root, as thoſe of the common Arum. This hath not yet flowered in England, ſo I can give no further account of it. This grows naturally in Siberia, ſo requires a ſhady ſituation, and will bear the greateſt cold of this country.

Theſe plants are preſerved in the gardens of the curious in England and Holland, more for the ſake of variety than for beauty; for except the firſt ſort, there is not any of them which make much appearance; that indeed may be ſuffered to have a place againſt the wall of the ſtove, over which it will ſpread, and cover the nakedneſs of the wall; and the leaves remaining all the year, which are ſo remarkably perforated, make a ſingular appearance.

All the other ſorts of Dragon are tender plants, ſo will not live in this country, unleſs they are preſerved in the warmeſt ſtoves; the ſeveral American ſorts grow naturally in the woods in Jamaica, and other hot parts of America; the climbing ſorts twiſt themſelves round the trunks of trees, into which they faſten their roots, which are ſent forth from their joints, and riſe to the height of thirty or forty feet. Theſe climbing ſorts are eaſily propagated by cuttings, which, being very ſucculent, may be brought over to England in a box of dry hay, if they are packed up ſeparate, ſo as not to injure each other by the moiſture, which is apt to flow out at the part where they are cut off, which may occaſion a fermentation, and thereby rot the cuttings. When the cuttings arrive, they ſhould be planted in ſmall pots filled with light freſh earth, and plunged into a hot-bed of tanners bark, being very careful not to let them have too much moiſture until they have taken root, leſt it rot them: when they have taken root, they muſt be frequently refreſhed with water; and when they are grown pretty large, they ſhould be placed in the bark-bed in the ſtove, where they muſt be placed near ſome ſtrong plants, to which they may faſten themſelves, otherwiſe they will not thrive; for though they will ſend forth roots at their joints, which will faſten to the mortar of the ſtove, when placed againſt the wall, yet they will not thrive near ſo well as againſt a ſtrong plant, which will afford them nouriſhment.

The other ſorts are propagated by offſets from their roots; theſe may be procured from the countries of their growth, and ſhould be planted in tubs of earth, about a month before they are put on board the ſhip to tranſport them; theſe tubs ſhould be placed in a ſhady ſituation until they have taken root. In their paſſage great care ſhould be had to keep them from ſalt water, as alſo not to let them have too much water given them; for if they have a little water once or twice a week at moſt, while they are in a hot climate, and when they are come into a cooler climate, once in a fortnight, this will be ſufficient for them; and it ſhould be done ſparingly, leſt it rot them; for if the tops of the plants ſhould decay for want of water in their paſſage, if the roots are not rotted, they will ſoon recover with proper care.

When the plants arrive, they ſhould be tranſplanted into pots filled with light freſh earth, and plunged into a hot-bed of tanners bark, and gently watered until they have taken good root, after which time they will require to be frequently refreſhed with water; but as their ſtems are very ſucculent, they muſt not have too much moiſture. Theſe plants ſhould be conſtantly kept in the ſtove, where, in hot weather, they ſhould have freſh air admitted to them; but in winter they muſt be kept very warm, otherwiſe they cannot be preſerved in this country.

Theſe plants will riſe to the height of three, four, or five feet, and will afford a very agreeable variety amongſt other tender exotic plants in the ſtove.

DRACUNCULUS PRATENSIS. See ACHILLEA.

DRAGON. See DRACONTIUM.

DROSERA. Ros Solis, or Sun-dew.

We have two or three ſpecies of this plant, which grow naturally upon bogs in many parts of England, and there are three or four other ſorts, which are natives of warmer countries; but as theſe cannot be cultivated in gardens, unleſs where there are bogs, it would be needleſs to deſcribe them.

The common round-leaved ſort is uſed in medicine, ſo is gathered by the herb-folks who ſupply the markets.

DRYAS, Cinquefoil Avens.

There are two ſpecies of this genus, which grow naturally in Scotland and Ireland, upon mountainous places, where the ſoil is wet; one of them hath five petals to the flower, and winged leaves, the other hath eight petals to the flower, and ſimple leaves; but as neither of the plants make much appearance, they are rarely preſerved except in ſome botanic gardens for variety.

DULCAMARA. See SOLANUM.

DUNGS are deſigned to repair the decays of exhauſted or worn-out lands, and to cure the defects of land, which are as various in their qualities as the dungs are, that are uſed to meliorate and reſtore them: ſome lands abound too much in coldneſs, moiſture, and heavineſs; others again are too light and dry, and ſo, to anſwer this, ſome dungs are hot and light, as that of ſheep, horſes, pigeons, &c. others again are fat and cooling, as that of oxen, cows, hogs, &c. And as the remedies that are to be uſed muſt be contrary to the diſtempers they are to cure, ſo the dung of oxen, cows, and hogs, muſt be given to clean, dry, light earths, to make them fatter and cloſer, and hot and dry dungs to meliorate cold, moiſt, and heavy lands.

There are two peculiar properties in dungs, the one is to produce a certain ſenſible heat, capable of producing ſome conſiderable effect, which properties are ſeldom found but in the dung of horſes and mules, while it is newly made, and a little moiſt; the other property of dung is, to fatten the earth and render it more fruitful.

The dung of horſes and mules is of admirable uſe in gardens in the winter time, becauſe it then animates and enlivens all things; and, in ſome meaſure, ſupplies the office which is performed by the heat of the ſun in the ſummer time, affording us all the novelties of the ſpring, as Aſparagus, Cucumbers, Radiſhes, ſallads, &c. Horſe dung is the beſt improvement for cold jejune lands that we can procure in any quantity; but yet horſe dung being uſed alone, or when it is too new, is frequently prejudicial to ſome plants; and if it be ſpread thin over lands in the ſummer time, it is of very little ſervice, becauſe the ſun, drawing out all the virtue and goodneſs of it, renders it little better than thatch or dry ſtraw; and though too much of it can ſcarcely be uſed in a kitchen-garden for Cabbages, Cauliflowers, and all other plants that grow there, and require abundance of nouriſhment; yet may it be a fault to lay too much of it on corn-lands, becauſe it produces abundance of ſtraw.

In very cold moiſt land, I have frequently ſeen new horſe dung buried as it came from the ſtable, and always obſerved that the crops have ſucceeded better, than where the ground was dreſſed with very rotten dung.

Horſe dung being of a very hot nature, is beſt for cold lands, and cow dung for hot lands; and being mixed together, may make a very good manure for moſt ſorts of ſoil, and for ſome they may be mixed with mud.

Sheeps dung and deers dung differ not much in their quality, and are eſteemed by ſome the beſt of dungs for cold clays. Some recommend them to be beat into powder, and ſpread very thin over autumn or ſpring crops, about four or five loads to an acre, after the ſame manner as aſhes, malt duſt, &c. are ſtrewed.

This I have ſeen practiſed upon corn, and alſo upon graſs land, to great advantage for the firſt year; but theſe light dreſſings do not laſt long, therefore require to be often repeated.

In Flanders and other places, they houſe their ſheep at nights in places ſpread with clean ſand, laid about five or ſix inches thick, which, being laid on freſh every night, is cleared out once a week; this mixture of ſand and dung makes an excellent dreſſing for ſtrong land, for the dung and urine of the ſheep is a very rich manure, bears a conſiderable price, and is an excellent manure for all ſtiff cold land: and Mr. Quinteney is of opinion, that it is the greateſt promoter of fruitfulneſs in all ſorts of ground.

Others recommend hogs dung as the fatteſt and moſt beneficial of all ſorts of dungs; and ſay, that one load of it will go as far as two loads of other dung, and that it is the beſt of all dungs for fruit-trees, eſpecially for Pear and Apple-trees in a light ſoil, and a very rich dung for graſs. I have often uſed this dung to fruit-trees when it was well rotted, and have found it the moſt beneficial to them of any manure.

The dung of pigeons, hens, and geeſe, are great improvers of meadow or corn land, the firſt of theſe being the beſt ſuperficial improvement that can be laid on meadow or corn land: but before it is uſed, it ought to have lain abroad out of the dove-houſe ſome time, that the air may have a little ſweetened it, and mollified the fiery heat that is in thoſe dungs.

Eſpecially it is good for cold, wet, clayey lands; but it ought to be dried before it be ſtrewed, becauſe it is naturally apt to clod in wet; and it ſhould be mixed with earth or ſand to keep it from clinging together, that it may be ſtrewed thin, being naturally very hot and ſtrong.

Some recommend the dung of pigeons, and alſo of other fowls, as the beſt manure for Aſparagus, Strawberries, or any ſorts of flowers; but this ſhould be rotted and well mixed with the earth, before it is uſed to flowers.

Monſieur Gentil approves of pigeons dung, as being good for ſuch trees whoſe leaves are apt to turn yellow, if they grow in free ſoils that are rather cold than hot, provided the heat of it has been abated by lying two or three years in the dunghill; but this ſhould be applied in autumn, and in ſmall quantities.

This being ſpread about an inch thick at the foot of a tree, whoſe leaves are yellow, and being left there till March, he recommends as very uſeful in cold and moiſt ſoils.

The dung of poultry being hot and full of ſalts, tends much to facilitate vegetation, and is abundantly quicker in its operation than the dung of animals which feed on herbs.

Sir Hugh Plat ſays, one load of grain will enrich ground more than ten loads of common dung; which if it be true, it is rational to ſuppoſe, that if ſimple grain, by only infuſion in the mixture of compoſts, has a very good effect, it will be more powerful when it has paſſed through the bodies of animals.

Human dung is a great improver of all cold ſour lands, and eſpecially if it be mixed with other earths or dungs to give it a fermentation.

But there is not any ſort of manure equal to the cleanſing of London ſtreets, for all ſtubborn clayey ſoils; the parts of which will be better ſeparated, and in a much leſs time, with this manure, than with any other compoſt whatever; and where it can be obtained, is extremely well worth procuring, either for corn, graſs, or garden land.

DURANTIA. Lin. Gen. Plant. 704. Caſtorea. Plum. Nov. Gen. 30. tab. 17.

The Characters are,

The flower hath a permanent empalement of one leaf, which is erect, and cut into five acute ſegments at the top, and ſits upon the germen; the flower is of the ringent kind, with one petal, having a long tube, which opens at the top in two lips; the upper lip is oval, erect, and concave; the under is divided into four equal ſegments, which are round. It hath four ſhort ſtamina, ſituated in the bottom of the tube, the two middle being a little ſhorter than the other, terminated by proſtrate ſummits; the germen which is ſituated under the flower, ſupports a long ſlender ſtyle, crowned by a headed ſtigma. The germen afterward becomes a globular berry, terminated by three acute points, having one cell incloſing four angular ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, the flower having two long and two ſhorter ſtamina, and the ſeeds being included in a capſule.

The title which was firſt given by father Plumier to this genus, was Caſtorea, in memory of Caſtor Durant, a phyſician of Rome, who publiſhed a hiſtory of plants in Italian, which was printed at Rome in 1585. Dr. Linnæus has now altered the title of the genus, and inſtead of the chriſtian name, he has given it the ſurname of the ſame perſon.

The Species are,

1. Durantia (*Plumeiri*) ſpinoſa. Lin. Sp. Plant. 637. *Prickly Durantia.* Caſtorea repens ſpinoſa. Plum. Nov. Gen. 30. *Creeping prickly Caſtorea.*
2. Durantia (*Racemoſa*) inermis. Lin. Sp. Plant. 637. *Durantia without thorns.* Caſtorea racemoſa flore cæruleo, fructu croceo. Plum. Nov. Gen. 30. *Branching Caſtorea with a blue flower and Saffron-coloured fruit.*
3. Durantia (*Erecta*) caule erecto ſpinoſo, foliis ovatis integerrimis, floribus racemoſis. *Durantia with an upright prickly ſtalk, oval entire leaves, and flowers growing in long bunches.* Jaſminum folio integro, obtuſo, flore cæruleo racemoſo, fructu flavo. Sloan. Cat. Jam. 169. *Jaſmine with entire obtuſe leaves, blue flowers growing in bunches, and a yellow fruit.*

The firſt ſort hath many trailing branches, which are armed with hooked thorns at every joint, and are garniſhed with oblong leaves, which are placed without order, and are ſlightly ſawed on their edges; the flowers come out from the ſide of the ſtalks in pretty long bunches, like thoſe of the common Currant; they are of a pale bluiſh colour, and ſucceeded by brown berries not unlike the fruit of the Hawthorn; theſe have one cell, and incloſe four angular ſeeds.

The ſecond ſort hath a branching woody ſtalk, which riſes ſeven or eight feet high; the branches are garniſhed with oval ſpear-ſhaped leaves three inches long, and one and a half broad in the middle; they are ſawed on their edges, of a lucid green colour, and ſtand oppoſite. The flowers are produced in long bunches at the end of the branches; theſe are blue, and ſucceeded by pretty large, round, yellow berries, which contain four angular ſeeds.

The third ſort riſes with a ſtrong woody ſtem to the height of ten or twelve feet, covered with a white bark, dividing into many branches, which are armed with ſharp thorns on their ſide; theſe are garniſhed with oval ſtiff leaves one inch long, and three quarters broad. The flowers come out in long bunches from the end of the branches, which are blue, and are ſucceeded by ſmall, round, yellow berries, which contain four angular ſeeds. I received this from the late Dr. Houſtoun, who found it growing in Jamaica.

The plants are natives of warm countries, ſo they require a ſtove to preſerve them in England; they are propagated by ſeeds, which ſhould be ſown in ſmall pots, and plunged into a hot-bed of tanners bark; and when the plants are fit to remove, they muſt be planted each into a ſeparate ſmall pot filled with light earth, and plunged into the hot-bed again, obſerving to ſhade them till they have taken new root, then they muſt be treated in the ſame manner as other plants from the ſame country.

The ſecond ſort may be propagated by cuttings, which may be planted in any of the ſummer months; but theſe ſhould be plunged into a moderate hot-bed, and ſhaded from the ſun till they have taken root, then they may be treated in the ſame manner as the ſeedling plants. This ſort is not ſo tender as the other two, ſo may be placed in the open air in ſummer; and if they are kept in a moderate temperature of warmth in the winter, they will thrive better than in great heat. I kept ſome of the plants of this ſort three winters, in a dry warm glaſs caſe without fires, and they have ſucceeded pretty well; but the winter 1762 proving ſevere, cauſed their leaves to fall, but ſince they have put out again very well.

DWARF-TREES. Theſe were formerly in much greater requeſt than they are at preſent; for though they have many advantages to recommend them, yet the diſadvantages attending them greatly over-balance; and ſince the introducing of eſpaliers into the Engliſh gardens, Dwarf-trees have been in little eſteem for the following reaſons:

1ſt, The figure of a Dwarf-tree is very often ſo much ſtudied, that, in order to render the ſhape beautiful, little care is taken to procure fruit, which is the principal deſign in planting theſe trees.

2dly, The branches being ſpread horizontally near the ſurface of the ground, render it very difficult to dig or clean the ground under them.

3dly, Their taking up too much room in a garden (eſpecially when they are grown to a conſiderable ſize) ſo that nothing can be ſown or planted between them.

4thly, Theſe trees ſpreading their branches near the ground, continually ſhade the ſurface of the earth; ſo that neither the ſun nor air can paſs freely round their roots and ſtems, to diſſipate noxious vapours; whereby the circumambient air will be continually replete with crude rancid vapours, which, being drawn in by the fruit and leaves, will render its juices crude and unwholſome, as well as ill taſted.

It is alſo very difficult to get to the middle of theſe Dwarf-trees in the ſummer, when their leaves and fruit are on the branches, without beating off ſome of the fruit, and breaking the young ſhoots; whereas, the trees on an eſpalier can at all times be come at on each ſide, to tie up the new ſhoots, or to diſplace all vigorous ones, which, if left on, would rob the trees of their nouriſhment.

Add to this, the fruit-buds of all ſorts of Pears and Apples, and moſt ſorts of Plumbs and Cherries, are firſt produced at the end of the former year's ſhoot, which muſt be ſhortened in order to keep the Dwarfs to their proper figure, ſo that the fruit-buds are cut off, and a greater number of branches are obtained, than can be permitted to ſtand; ſo that all thoſe ſorts of fruit-trees, whoſe branches require to be trained at their full length, are very improper to train up as Dwarfs; and the Peaches and Nectarines which will bear amputation, are too tender to be trained ſo in this country.

Theſe evils being entirely remedied by training the trees to an eſpalier, hath juſtly gained them the preference; however, if any one has a mind to have Dwarf-trees, notwithſtanding what has been ſaid, I ſhall lay down a few rules for their management.

If you deſign to have Dwarf Pear-trees, you ſhould bud or graft them on Quince ſtocks; but as many ſorts of Pears will not thrive if they are immediately budded or grafted on Quince ſtocks, ſo ſome of thoſe ſorts which will take freely, ſhould be firſt budded on the Quince ſtocks; and when theſe have ſhot, the ſorts you intend to cultivate, ſhould be budded into theſe; for free ſtocks are apt to make them ſhoot ſo vigorouſly, as not to be kept within bounds. Theſe grafts or buds ſhould be put in about four or ſix inches above the ſurface of the ground, that the heads of the trees may not be advanced too high; and when the bud or graft has put out four ſhoots, you ſhould ſtop the end of the ſhoots, to force out lateral branches.

Two years after budding, theſe trees will be fit to tranſplant where they are to remain; for though many people chuſe to plant trees of a greater age, yet they ſeldom ſucceed ſo well as young ones. The diſtance theſe trees ſhould be planted is twenty-five or thirty feet aſunder, for leſs will not do if the trees thrive well. The ground between them may be cultivated for kitchen-garden herbs while the trees are young, but you ſhould not ſow or plant too near their roots.

In order to train your trees regularly, you ſhould drive ſtakes into the ground round the tree, to which the branches ſhould be faſtened down with liſt in a horizontal poſition; for if they are ſuffered to grow perpendicularly while young, they cannot be afterwards reduced without great violence to any tolerable figure. The neceſſary directions to be afterwards followed are, not to ſuffer any branches to croſs each other; and always in ſhortening any ſhoots be ſure to leave the uppermoſt eye outwards, whereby the hollowneſs in the middle of the tree will be better preſerved; and be careful to rub off all perpendicular ſhoots in the middle of the trees, as ſoon as they are produced. The other neceſſary rules you will find under the article of PRUNING.

The ſorts of Pears which do beſt in Dwarfs, are all ſummer and autumn fruits; for winter Pears are not worth planting in Dwarfs, they ſeldom bearing well, nor are ever well taſted, and commonly are very ſtony, becauſe they are commonly grafted on Quince ſtocks.

Apples are alſo planted in Dwarfs, moſt of which are now budded or grafted on Paradiſe ſtocks; but as theſe are for the moſt part of a ſhort duration, they are not profitable, and are fit only for ſmall gardens as a matter of curioſity, producing fruit ſooner, and in greater plenty, than when they are upon Crab or Apple ſtocks.

The diſtance theſe trees ſhould be planted, if on Paradiſe ſtocks, ſhould be ſix or eight feet, and upon Dutch ſtocks eighteen or twenty; but if on Crab ſtokcs, twenty-five or thirty feet aſunder each way. The management of theſe being the ſame with Pears, I need not repeat it.

Some perſons alſo plant Apricots and Plumbs for Dwarfs, but theſe ſeldom ſucceed well, as being of a tender conſtitution; and thoſe which will produce fruit on Dwarfs, are much more likely to do ſo when trained on an eſpalier, where they can be much better managed; and therefore I judge it much the better method, as being more certain, and the trees will make a better appearance.

E.

EARTH is the principal matter whereof our globe conſiſts; the character of which, according to Dr. Boerhaave, is, that it is a foſſil body, neither diſſoluble by fire, water, nor air; that it is inſipid and tranſparent; more fuſible than ſtone; ſtill friable, and containing uſually a ſhare of fatneſs.

There is no ſuch thing as a ſtrictly ſimple earth. Mr. Boyle ſays, that it doth not appear, that nature, any more than art, affords an elementary earth; at leaſt, ſome which appear of the ſimpleſt ſorts are found, upon examination, to have qualities not aſcribed to pure earth.

Of ſuch earths ſome are ſimple and immutable, as chalk, pumice, and rotten ſtone; others compound and fatty; of which kind are all boles, red, white, and brown; fullers earth, and divers kinds of medicinal earths, as the Cretica, Hungarica, Lemnian earth, and others.

Which earth are all reſolvable into oil, a little acid ſalt, &c. and a calx, which is the baſis, or the earth properly ſo called.

Sand is by naturaliſts generally ranked as a ſpecies of earth, though not very properly; in that ſands, ſtrictly ſpeaking, are a ſort of cryſtals, or little tranſparent pebbles, and are calcinable; and, by the addition of a fixed alkaline ſalt, fuſible and convertible into glaſs.

The fat earth is rendered fertile by the means of ſand, and becomes fit to feed and nouriſh vegetables, &c. for pure earth is liable to coaleſce into a hard coherent maſs, as in clay; and earth thus embodied, and as it were glued together, would be very unfit for the nouriſhment of plants.

But if hard ſand, i. e. cryſtals, which are indiſſoluble in water, and ſtill retain the ſame figure, be intermixed with ſuch earth, they will keep the pores of the earth open, and the earth itſelf looſe and incompact, and by that means give room for the juices to move, aſcend, &c. and for plants to be nouriſhed thereby.

Thus a vegetable, being planted either in the ſand alone, or in the fat glebe and earth alone, receives no growth or increment, but is either ſtarved or ſuffocated; but mix the two, and the maſs becomes fertile.

In effect, by means of ſand the earth is rendered, in ſome meaſure, organical; pores and interſtices being hereby maintained or preſerved, ſomething analogous to veſſels is effected, by which the juices of the earth may be conveyed, prepared, digeſted, circulated, and at length excerned and thrown off in the roots of plants.

The earth is made up of two parts; the firſt the containing part, i. e. the body, bed, or couch: the ſecond the part contained, and thoſe are the nitrous or ſulphureous particles, or prolific ſalts. The firſt is a lifeleſs inanimate maſs, and is only the receptacle of the other; for the earth, conſidered ſimply, and abſtracted from the before-mentioned nitrous and prolific ſalts, is a lifeleſs, dead, and inanimate maſs; but by the co-operation of water, ſun, and air, is put into motion, and promotes the work of vegetation: but if it were ſtript of thoſe prolific ſalts and ſpirituous particles, would produce no manner of plant, herb, &c. that ſhould be planted or ſown in it.

Theſe nitrous particles, or prolific ſalts, are of various and different qualities; and according as the earth is more or leſs ſtored with all or ſome of them, it is more or leſs productive; and according as it abounds with ſome of them more than others, differing from one another in contexture, it conſtitutes the different ſpecies or kinds of ſoils adapted to the propagation of different plants, the pores of whoſe roots are formed to receive, and whoſe nature is to attract, thoſe ſalts that are congenial to them.

Some diſtinguiſh earths into three claſſes, ſand, loam, and clay, as thoſe upon one or other of which all others do in ſome reſpects depend.

Gravel, and all the open ſoils, till the loam is come at, are of the ſandy kind.

Thoſe binding earths from the loam downwards, till the ſtiffneſs of chalk may be come at, may be reckoned of the clay kind.

All theſe ſorts of earth have a little tendency to vegetation, and have their ſalts proper for it, but in a different proportion; as a peck of clay may probably have double the quantity of ſalts in it that a peck of loam has, and a peck of loam may have ſix times the quantity of ſalts that a peck of ſand has.

Loam. Some call the ſuperficial earth that we meet with in England by this name, without having regard to what proportion of ſand and clay it contains: others again call that earth loam, that inclines more to clay than ſand. Some by loam mean that ſort of earth that equally partakes of ſand and clay, being a medium between ſand and clay, which they call mother earth; but the true definition of loam is, that ſort of earth which is fat and ſlippery, not of ſo cloſe a texture as clay, nor too looſe and ſandy, but of a middle nature between them, and is eaſily diſſolved by froſt, and gentle or eaſy to be wrought. This is one of the beſt ſoils for moſt eſculent plants and roots.

This mother earth, they ſay, may be in colour either black or yellow, and of which of theſe colours ſoever it be, plants of moſt ſorts will grow in it.

Sand and clay likewiſe produce certain plants, which are natural to each of them, and conſequently will thrive better in them than in any other ſoil.

But ſand is apt to precipitate thoſe plants that are ſet in it, earlier than clay, and will cauſe them to germinate near a month ſooner than thoſe that grow in clay, and that for this reaſon, becauſe the ſalts which are in ſand, are liable to be put in motion by the leaſt approach of the warmth of the ſun; but as ſand is quick in the operation, the ſalts are ſoon exhaled and ſpent.

Clay. The pores of clay are more cloſely compacted together, and do not ſo eaſily give out thoſe ſalts that are contained in it; nor can the fibres of every tender plant make their way through it in queſt of their proper nutriment.

But if the parts of the clay be opened, by digging and breaking it into ſmall particles, and thoſe parts be kept open by a mixture of ſome ſharp ſand, or ſome other body of the like quality, the effects of its vigour will plainly appear.

Some diſtinguiſh the ſeveral temperaments of the earth either into a light, ſandy, or looſe contexture, or into thoſe of a ſtiff, clayey, or cloſe one, either of which have their reſpective good qualities; and all of them, when they are in their extremes, require art to render them uſeful and beneficial in the production and growth of plants.

A light, ſandy, or looſe earth, requires a proper ligature, and ſhould have a compoſt of a heavier nature; and thoſe that are heavy, clayey, and cloddy, ſhould have a compoſt of a more fiery ſprightly nature, that will inſinuate itſelf into the heavy, lumpy, indigeſted clods, which would otherwiſe very much obſtruct the buſineſs of vegetation.

A good earth ſhould be of a blackiſh colour, fat, pliant, or eaſy to be digged; it ſhould be neither cold nor light; it ought to have no ill ſmell or taſte, and it ſhould be of the ſame quality three or four feet deep for trees, which, if they have not that depth, will languiſh and decay after they have been planted ſix years. But this depth is not required for fruit-trees, which will thrive very well if they have two feet and a half of good earth, and generally produce the moſt generous fruits, when their roots ſpread near the ſurface of the earth.

In order to know whether the earth has any ill ſmell or taſte, they direct to lay a handful of it to ſoak in water for ſeven or eight hours, and afterwards to ſtrain it, and taſte and ſmell it, by which the taſte or ſmell will eaſily be perceived.

EARWIGS.

Theſe are very troubleſome vermin in a garden, eſpecially where Carnations are preſerved; for they are ſo fond of theſe flowers, that if care is not taken to prevent them, they will entirely deſtroy them, by eating off the ſweet part at the bottom of the petals or leaves. To prevent which, moſt people have ſtands erected, which have a baſon of earth or lead round each ſupporter, which is conſtantly kept filled with water. See the article CARNATION.

Others hang the hollow claws of crabs and lobſters upon ſticks in divers parts of the garden, into which theſe vermin get; and by often ſearching them, you will deſtroy them without much trouble, which will be of great ſervice to your wall fruit, for theſe are great deſtroyers of all ſoft fruits.

EBENUS. Lin. Gen. Nov. Barba Jovis. Tourn. Inſt. R. H. tab. 419. Ebony.

The CHARACTERS are,

The empalement of the flower is of one leaf, which is divided into five acute ſegments at the top; the flower is of the butterfly kind; the vexillum is obtuſe and reflexed; the wings are equal in length with the vexillum; they are broad and roundiſh; the keel is ſhorter and turns upwards. It hath ten ſtamina, nine joined, ſtanding together, and the other ſeparate, terminated by ſingle ſummits. In the bottom is ſituated an oblong germen, ſupporting a riſing ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes an oblong ſwelling pod, opening with two valves, and incloſing three or four kidney-ſhaped ſeeds. This is diſtinguiſhed from Trifolium, by the bracteæ which are ſituated between the flowers on the ſpike.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, the flowers having ten ſtamina in two bodies.

We know but one SPECIES of this genus, viz.

EBENUS. Lin. Sp. Plant. 764. Ebony. Barba Jovis lagopoides, Cretica, fruteſcens, incana, flore ſpicato purpureo amplo. Breyn. Prod. 2. *Shrubby Haresfoot Jupiter's Beard of Crete with hoary leaves, and a large purple flower growing in ſpikes.*

This plant grows naturally in Crete, and in ſome of the iſlands of the Archipelago; it riſes with a ſhrubby ſtalk three or four feet high, which puts out ſeveral ſide branches, garniſhed with hoary leaves at each joint, which are compoſed of five narrow ſpear-ſhaped lobes, which join at their tails to the foot-ſtalk, and ſpread out like the fingers of a hand. The branches are terminated by thick ſpikes of large purple flowers, which are of the butterfly or Pea-bloom kind; the ſpikes are from two to three inches long, ſo make a fine appearance, eſpecially when the plants are ſtrong, and have many ſpikes of flowers on them. It flowers in June and July, and in very warm ſeaſons will ſometimes perfect their ſeeds in England.

This is propagated by ſeeds, which ſhould be ſown in the autumn, for thoſe which are ſown in the ſpring often fail; they muſt be ſown in pots, and placed under a frame in the winter, where they may be protected from froſt. In the ſpring the plants will come up, which ſhould be kept clean from weeds, and refreſhed now and then with water. When theſe have acquired ſtrength enough to be removed, they ſhould be each planted in a ſeparate ſmall pot filled with light earth, and plunged into a moderate hot-bed juſt to promote their taking new root; then they ſhould be gradually inured to bear the open air, into which they ſhould be removed the latter end of May, placing them in a ſheltered ſituation, where they may remain till autumn, when they muſt be removed into ſhelter; for theſe plants will not live in the open air through the winter, nor ſhould they be too tenderly treated, leſt they draw up weak. I have found them ſucceed beſt when placed in an airy glaſs-caſe without fire in winter, where they will have more ſun and air than in a green-houſe. During the winter ſeaſon, the plants muſt be ſparingly watered, but in the ſummer they will require to be often refreſhed. The other management is the ſame as for other of the hardier exotic plants, among which this will make a fine variety.

EBULUS. See SAMBUCUS.

ECHINATE SEEDS [of echinus, *Lat.* a hedge-hog,] ſuch ſeeds of plants as are prickly and rough.

ECHINOMELOCACTUS. See CACTUS.

ECHINOPHORA. Lin. Gen. Plant. 292. Tourn. Inſt. R. H. 656. tab. 423. [of Ἐχῖνος, a hedge-hog, and φέρω, *Gr.* to bear.] Prickly Parſnep.

The CHARACTERS are,

It hath an umbellated flower; the general umbel is compoſed of many ſmaller, the intermediate being the ſhorteſt; the involucrum of the general umbel ends in acute thorns; thoſe of the rays are turbinated, of one leaf, cut into ſix unequal parts, with acute points; the perianthium is divided into five parts, and ſits on the germen; the general umbel is uniform; the flowers have five unequal petals which ſpread open; they have each five ſtamina, terminated by roundiſh ſummits. Under the perianthium is ſituated an oblong germen within the empalement, ſupporting two ſtyles, crowned by ſingle ſtigmas; the germen afterward turns to two ſeeds, which are incloſed in the hard empalement.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, the flower having five ſtamina and two ſtyles.

The SPECIES are,

1. ECHINOPHORA (*Spinoſa*) foliolis ſubulato-ſpinoſis integerrimis. Lin. Sp. Plant. 344. *Prickly-headed Parſnep, with awl-ſhaped prickly leaves which are entire.* Echinophora maritima ſpinoſa. Tourn. Inſt. 656. *Prickly maritime Parſnep.*
2. ECHINOPHORA (*Tenuifolia*) foliolis inciſis inermibus. Lin. Sp. Plant. 344. *Prickly-headed Parſnep, whoſe ſmall leaves are cut, but have no thorns.* Echinophora paſtinacæ folio. Tourn. Inſt. 656. *Prickly-headed Parſnep with a Carrot leaf.*

Theſe plants grow naturally on the borders of the Mediterranean ſea; they are preſerved in the gardens of botany for the ſake of variety; they have both perennial roots, which creep in the ground; the firſt hath branching ſtalks, growing five or ſix inches high, which are garniſhed with ſhort thick leaves, that terminate in two or three ſharp thorns; they are placed by pairs oppoſite: the flowers grow in an umbel, ſitting upon a naked foot-ſtalk, which ariſes from the ſide of the ſtalk; they are white, and under the umbel is ſituated an involucrum, compoſed of ſeveral leaves, which terminate in ſharp ſpines. It flowers in June, but ſeldom ripens ſeeds in this country.

The ſecond ſort riſes near a foot and a half high; from the principal ſtalk are ſent out two ſide branches at every joint, which are placed oppoſite; the lower part is garniſhed with leaves, which are finely divided like thoſe of the Carrot; the flowers grow in ſmall umbels at the extremity of the branches, having a ſhort prickly involucrum. This flowers in July, but doth not ripen ſeeds in England.

Theſe plants are propagated by their creeping roots in England, as they do not produce ſeeds here: the beſt time to tranſplant them is the beginning of March, a little before they ſhoot. The roots ſhould be planted in a gravelly or ſandy ſoil, and in a warm ſituation, or otherwiſe they ſhould be covered in the winter to prevent the froſt from deſtroying them,

ECHINOPS. Lin. Gen. Plant. 829. Echinopus. Tourn. Inſt. R. H. tab. 463. Globe Thiſtle.

The CHARACTERS are,

It hath a permanent perianthium, which is oblong, angular, and imbricated; the flower hath one funnel-ſhaped petal, which is divided at the top into five parts, which ſpread open and are reflexed. It hath five ſhort hairy ſtamina, terminated by cylindrical ſummits. In the bottom of the tube is ſituated an oblong germen, ſupporting a ſlender ſtyle the length of the tube, crowned by two oblong depreſſed ſtigmas which turn back; the germen afterward becomes an oblong oval ſeed narrowed at the baſe, but obtuſe and hairy at the top.

This genus of plants is ranged in the firſt ſection of Linnæus's ſeventeenth claſs, intitled Syngeneſia Polygamia Æqualis. This ſection includes thoſe plants which have only hermaphrodite fruitful florets.

The SPECIES are,

1. ECHINOPS (*Sphærocephalus*) capitulis globoſis pubeſcentibus. Lin. Sp. Plant. 1314. *Globe Thiſtle with globular heads and hairy leaves.* Echinopus major. J. B. 3. p. 69. *Greater Globe Thiſtle.*
2. ECHINOPS (*Ritro*) capitulo globoſo, foliis ſupra glabris. Lin. Sp. Plant. 1314. *Globe Thiſtle with a globular head, and the upper ſide of the leaves ſmooth.* Echinopus minor. J. B. 3. 72. *Smaller Globe Thiſtle.*
3. ECHINOPS (*Strigoſus*) capitulis faſciculatis calycibus, lateralibus ſterilibus, foliis ſuprà ſtrigoſis. Lin. Sp. Plant. 1315. *Globe Thiſtle with bundled heads, whoſe ſide empalements are barren, and wing-pointed leaves.* Echinopus minor annuus, magno capite. Tourn. Inſt. 463. *Smaller annual Globe Thiſtle with a large head.*
4. ECHINOPS (*Græcus*) caule unicapitato, foliis ſpinoſis, omnibus pinnatifidis villoſis, radice reptartice. *Globe Thiſtle with one head on each ſtalk, prickly leaves, which are all wing-pointed and woolly, and a creeping root.* Echinopus Græcus, tenuiſſime diviſus & lanuginoſus, capite minori cæruleo. Tourn. Cor. 34. *Greek Globe Thiſtle whoſe leaves are divided into narrow ſegments and are woolly, with a ſmaller blue head.*

The firſt is the common Globe Thiſtle, which has been long cultivated in ſome gardens for the ſake of variety; this grows naturally in Italy and Spain; it hath a perennial root, from which ariſe many ſtalks that grow to the height of four or five feet; theſe are garniſhed with long jagged leaves, which are divided into many ſegments almoſt to the midrib, the jags ending in ſpines; they are of a dark green on their upper ſide, but woolly on their under; the flowers are collected in globular heads, ſeveral of theſe grow upon each ſtalk; the common hath blue flowers, but there is a variety of it with white. It flowers in July, and the ſeeds ripen in Auguſt.

This plant is eaſily propagated by ſeeds, which, if permitted to ſcatter, the plants will come up in plenty, ſo a few of them may be tranſplanted to the places where they are deſigned to remain to flower; they require no other culture but to keep them clean from weeds: the ſecond year they will flower and produce ſeeds, and the roots will continue two or three years after; but if the ſeeds ſcatter, the plants will become troubleſome weeds; to prevent which, the heads ſhould be cut off as ſoon as the ſeeds are ripe.

The ſecond ſort grows in the ſouth of France and in Italy; this hath a perennial creeping root, which ſends up ſeveral ſtrong ſtalks that riſe two feet high, garniſhed with leaves, which are cut into many fine ſegments to the midrib, which are ſet with prickles, and are white on their under ſide: the ſtalks branch out toward the top; each of theſe branches is terminated by a globular head of flowers, which are ſmaller than thoſe of the firſt, and of a deeper blue; there is alſo a variety of this with white flowers. This flowers about the ſame time as the firſt, and is propagated in the ſame way. Theſe will both grow in almoſt any ſoil or ſituation.

The third ſort grows naturally in Spain and Portugal: this is an annual plant, which riſes with a ſtiff white ſtalk two feet high, garniſhed with divided leaves, ending in many points which have ſpines; their upper ſide is green, and covered with brown hairs, their under ſide white and woolly; the ſtalk is terminated by one large head of pale blue flowers. Theſe appear in July, and if the ſeaſon proves warm and dry, the ſeeds will ripen in autumn, but in wet cold years they rarely ripen here.

Theſe ſeeds ſhould be ſown in the ſpring, upon a border of light earth, where the plants are to remain; and they require no other management, but to thin them where they are too cloſe.

The fourth ſort grows naturally in Greece, from whence Dr. Tournefort ſent the ſeeds to the royal garden at Paris: this hath a perennial creeping root, by which it multiplies faſt enough; the ſtalks riſe about a foot high, and are cloſely garniſhed with leaves which are ſhorter and much finer divided than either of the former ſorts; theſe are hoary, and armed on every ſide with ſharp thorns; the ſtalks are terminated by one middle-ſized globular head of flowers, which in ſome are blue, and in others white. They appear the latter end of June, and in warm ſeaſons the ſeeds will ripen well in England. This is eaſily propagated by its creeping roots, or from ſeeds; it loves a dry ſoil and a warm ſituation.

ECHINUS, *Lat.* is the prickly head or cover of the ſeed or top of any plant, ſo called from its likeneſs to a hedgehog.

ECHIUM. Lin. Gen. Plant. 157. Tourn. Inſt. R. H. 135. tab. 54. [of Ἔχις, *Gr.* a viper, becauſe the ripe ſeed of this plant reſembles the head of a viper. It is called Herba Viperaria, becauſe the ancients believed that this plant killed vipers.] Viper's Bugloſs; in French, *Viperine.*

The CHARACTERS are,

The flower hath a permanent empalement, divided into five ſegments. It hath one petal with a ſhort tube, having an erect broad brim, cut into five parts, and is obtuſe; the two upper being longer than the lower, which are acute and reflexed. It hath five awl-ſhaped ſtamina, terminated by oblong proſtrate ſummits. In the bottom are ſituated four germen with one ſlender ſtyle, crowned by an obtuſe bifid ſtigma; the germen afterward become ſo many roundiſh pointed ſeeds, incloſed in the rough empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The SPECIES are,

1. ECHIUM (*Anglicum*) caule ſimplici erecto, foliis lanceolatis, floribus ſpicatis lateralibus, ſtaminibus corolla æquantibus. *Viper's Bugloſs with a ſingle erect ſtalk, having rough ſpear-ſhaped leaves, and flowers in ſpikes proceeding from the ſide, with the ſtamina equalling the petal.* Echium vulgare C. B. P. 254. *Common Viper's Bugloſs.*
2. ECHIUM (*Vulgare*) caule ſimplici erecto, foliis caulinis lanceolatis hiſpidis, floribus ſpicatis lateralibus ſtaminibus corollâ longioribus. *Viper's Bugloſs with a ſingle erect ſtalk, having rough narrow ſpear-ſhaped leaves, flowers growing in ſhort ſpikes on the ſides, and ſtamina longer than the petal.* Lycopſis Anglica. Lob. *Engliſh Lycopſis.*
3. ECHIUM (*Italicum*) corollis vix calycem excedentibus, margine villoſis. Hort. Upſal. 35. *Viper's Bugloſs, whoſe petals ſcarce exceed the empalement, having hairy borders.* Echium majus & aſperius, flore albo. C. B. P. 255. *Great rough Viper's Bugloſs with a white flower.*

4. Echium (*Luſitanicum*) corollis ſtamine longioribus. Lin. Sp. 200. *Viper's Bugloſs with the petal of the flower longer than the ſtamina.* Echium ampliſſimo folio, Luſitanicum. Tourn. *Portugal Viper's Bugloſs with a large leaf.*
5. Echium (*Creticum*) calycibus fructeſcentibus diſtantibus, caule procumbente. Lin. Hort. Upſal. 35. *Viper's Bugloſs with fruitful empalements growing at a diſtance, and a trailing ſtalk.* Echium Creticum latifolium rubrum. C. B. P. 254. *Broad-leaved Viper's Bugloſs of Candia, having a red flower.*
6. Echium (*Anguſtifolium*) caule ramoſo, aſpero, foliis calloſo-verrucoſis, ſtaminibus corollâ longioribus. *Viper's Bugloſs with a rough branching ſtalk, warted leaves, and ſtamina longer than the petal.* Echium Creticum anguſtifolium rubrum. C. B. P. 254. *Narrow-leaved Viper's Bugloſs of Candia, having a red flower.*
7. Echium (*Fruticoſum*) caule fruticoſo. Hort. Cliff. 43. *Viper's Bugloſs with a ſhrubby ſtalk.* This is the Echium Africanum fruticans, foliis piloſis. Hort. Amſt. 2. p. 107. *Shrubby African Viper's Bugloſs, having hairy leaves.*

The firſt ſort grows naturally in Germany and Auſtria, from whence I received the ſeeds. This and our common Viper's Bugloſs, which is the ſecond, have been confounded by moſt of the writers on botany, who have ſuppoſed they were the ſame plant, whereas they are very different; for the leaves of this are ſhorter, and much broader than thoſe of the ſecond; the ſpikes of flowers are much longer, and the ſtamina of the flowers are in this equal in length with the petal; whereas thoſe of the ſecond ſtand out much beyond the petal, which is an eſſential difference.

The ſecond ſort grows naturally upon chalky lands in moſt parts of England: this is what Lobel titles Lycopſis Anglica, and has been generally taken for the common Echium.

The third ſort grows naturally in the ſouth of France, in Italy, and the iſle of Jerſey; this riſes with an upright hairy ſtalk; the flowers are produced in ſhort ſpikes on the ſide of the branches; they are ſmall, and ſcarce appear above the empalements; ſome plants have white flowers, and others are purpliſh; the empalements of the flowers are very hairy, and cut into acute ſegments.

The fourth ſort grows naturally in Portugal and Spain; the lower leaves of this are more than a foot long, and two inches broad in the middle, gradually leſſening to both ends; theſe are covered with ſoft hairs. The ſtalks grow two feet high; the flowers are in ſhort ſpikes coming from the ſide of the ſtalks; the petals of theſe are longer than the ſtamina.

The fifth ſort grows naturally in Crete; this hath trailing hairy ſtalks, which grow about a foot long, and put out ſeveral ſide branches, garniſhed with hairy ſpear-ſhaped leaves about three inches long, and three quarters of an inch broad, ſitting cloſe to the ſtalks. The flowers come out on ſlender ſpikes upon long foot-ſtalks, which come from the wings of the leaves; they are large, of a reddiſh purple colour, which turns to a fine blue when they are dried; theſe ſtand at a diſtance from each other on the ſpike. It is an annual plant, which flowers in July and decays in autumn.

The ſixth ſort hath branching ſtalks which grow a foot and a half long, declining toward the ground; they are covered with ſtinging hairs; the leaves are four inches long, and not more than half an inch broad; theſe are pretty much warted, and are hairy. The flowers grow in looſe ſpikes from the ſide of the ſtalks, and alſo at the end of the branches; they are of a reddiſh purple colour, but not ſo large as thoſe of the former ſort, and the ſtamina of theſe are longer than the petal. This is alſo an annual plant, which grows naturally in Crete.

Theſe are moſt of them biennial plants, except the fifth and ſixth ſorts, which are annual, and are the moſt beautiful of all the kinds: the ſeeds of theſe muſt be ſown every year, in the places where they are deſigned to remain; and the plants require no other culture but to keep them clean from weeds, and thin them where they grow too cloſe. In July they flower, and their ſeeds ripen in five or ſix weeks after. The ſeeds of the other ſorts being ſown in the ſpring, will the ſecond ſummer after produce flowers and ſeeds, after which they ſeldom continue. They all delight in a rubbiſhy gravelly ſoil, and will grow upon the tops of old walls or buildings; where, when once they have eſtabliſhed themſelves, they will drop their ſeeds, and thereby maintain a ſucceſſion of plants without any care, and on theſe places they appear very beautiful.

The ſeventh ſort grows naturally at the Cape of Good Hope, from whence the ſeeds were brought to Holland, where the plants are now preſerved in ſome curious gardens. This riſes with a ſhrubby ſtalk two or three feet high, dividing upward into ſeveral branches, garniſhed with oval leaves placed alternate, whoſe baſe ſits cloſe to the ſtalk; they are hairy, and of a light green colour. The flowers are produced ſingly between the leaves at the end of the branches; they are of a purple colour, and in ſhape much like thoſe of the fifth ſort. Theſe appear in May and June, but the ſeeds do not ripen in England.

It is propagated by ſeeds, when they can be obtained, which ſhould be ſown in pots filled with light ſandy earth ſoon after they are received. Theſe may be expoſed to the open air till the beginning of October, when the pots ſhould be placed under a frame, to guard them from froſt; but in mild weather, they ſhould be opened to have the free air, to prevent the ſeeds from vegetating till the winter is paſt; for if the plants come up at that ſeaſon, their ſtems will be weak and full of juice, and very liable to rot with damps; therefore it is much better if the plants do not come up till toward March, which is the uſual time of their appearing, when the ſeeds are not forced by warmth. When the plants are fit to remove, they ſhould be each planted into a ſmall pot filled with light earth, and placed under a frame to forward their putting out new roots; then they ſhould be gradually inured to bear the open air, and the latter end of May be placed abroad in a ſheltered ſituation, where they may remain till the beginning of October; at which time they muſt be removed into an airy glaſs-caſe, where they may enjoy the ſun and have free air in mild weather. During the winter ſeaſon theſe plants muſt be ſparingly watered; for as their ſtems are ſucculent, ſo much moiſture will cauſe them to rot. In the ſummer they ſhould be ſet abroad in a ſheltered ſituation, and treated in the ſame manner as other plants from the ſame country.

EDERA QUINQUEFOLIA. See Vitis.

EDGINGS. The beſt and moſt durable plant for edgings in a garden is Box; which, if well planted, and rightly managed, will continue in beauty ſeveral years: the beſt ſeaſon for planting this, is either in the autumn, or very early in the ſpring; for if you plant it late, and the ſeaſon ſhould prove hot and dry, it will be very ſubject to miſcarry, unleſs great care be taken to ſupply it with water. The beſt ſort for this purpoſe is the dwarf Dutch Box.

Theſe edgings are only planted upon the ſides of borders next walks, and not (as the faſhion was ſome years ago) to plant the edgings of flower-beds, or the edges of fruit-borders in the middle of gardens, unleſs they have a gravel-walk between them; which renders it proper to preſerve the walks clean, by keeping the earth of the borders from waſhing down into the walks in hard rains.

It was alſo the practice formerly to plant edgings of divers ſorts of aromatic herbs, as Thyme, Savory, Hyſſop, Lavender, Rue, &c. But as theſe very ſoon grow woody, ſo that they cannot be kept in due compaſs, and in hard winters they are often killed in patches, whereby the edgings are rendered incomplete, they are now ſeldom uſed for this purpoſe.

Some people make edgings of Daiſies, Thrift, Catchfly, and other flowering plants; but theſe alſo require

quire to be tranſplanted every year, in order to have them handſome; for they ſoon grow out of form, and are ſubject alſo to decay in patches; ſo that there is not any plant which ſo completely anſwers the deſign as Dwarf Box, which muſt be preferred to all others for this purpoſe.

EFFLORESCENCE, *Lat.* the blowing out of a flower.

To **EGERMINATE**, *Lat.* to bud or ſpring out.

EHRETIA. Trew. tab. 24.

The Characters are,

It hath a ſmall, permanent, bell-ſhaped empalement of one leaf, cut into five points; the flower hath one petal, whoſe tube is longer than the empalement, cut into five ſegments; it hath five awl-ſhaped ſpreading ſtamina the length of the corolla, terminated by roundiſh incumbent ſummits, and a roundiſh germen, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by an obtuſe indented ſtigma; the germen afterward becomes a round berry with one cell, incloſing four angular ſeeds.

This genus of plants is ranged in the firſt order of Linnæus's fifth claſs; intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

The Species are,

1. Ehretia (*Tinifolia*) foliis oblongo-ovatis integerrimis glabris, floribus paniculatis. Amœn. Acad. 5. p. 395. *Ehretia with oblong, oval, entire, ſmooth leaves, and flowers growing in panicles.*
2. Ehretia (*Bourreria*) foliis ovatis integerrimis lævibus, floribus ſubcorymboſis, calycibus glabris. Lin. Sp. 275. *Ehretia with oval entire leaves, flowers growing in a ſort of corymbus, and ſmooth empalements.* Bourreria fructibus ſucculentis. Jacq. Amer.

The ſeeds of the firſt ſort were ſent me from Jamaica in the year 1734, which ſucceeded in the Chelſea garden, where the plants have grown to the height of eight or nine feet, with ſtrong woody ſtems, and have ſeveral times produced their flowers, but have not perfected their ſeeds as yet in England. This is by Dr. Linnæus ſuppoſed to be the ſame plant mentioned by Sir Hans Sloane, under the title of Ceraſo affinis arbor baccifera racemoſa, flore albo pentapetalo, fructu flavo monopyreno eduli dulce. Hiſt. Jam. 2. p. 94. But I differ in my opinion from him, for the leaves of our plant are ſmoother, longer, and more pointed, and the corymbus of flowers is much longer than in Sir Hans's plant.

This hath a rough woody ſtalk, which divides into ſeveral irregular branches, garniſhed with oblong, oval, ſmooth leaves, nine inches long, three broad in the middle, ending in acute points; the flowers are white, and produced in an oblong corymbus toward the end of the branches; they have one petal in each, which is cut at the top into five ſegments which are reflexed. Theſe appear toward the end of July, but fall away without being ſucceeded by ſeeds.

The ſeeds of the ſecond ſort I received from Surinam, which ſucceeded in the Chelſea garden. This hath a woody upright ſtem, covered with a brown bark, ſending out branches regularly toward the top, garniſhed with ſmooth oval leaves placed alternate, having ſhort foot-ſtalks; the leaves are ſix inches long, and more than two broad, ending with blunt oval points. As this ſort hath not produced flowers here, ſo I can give no farther account of them. This Doctor Linnæus ſuppoſes to be the ſame with a plant figured by Mr. Cateſby, under the title of Pittonia ſimilis laureolæ foliis, floribus albis, baccis rubris. But in this he is alſo miſtaken, for there are plants in the Chelſea garden, which were raiſed from ſeeds ſent from the Bahama Iſlands, which are very different from the former.

Theſe plants are too tender to thrive abroad in England, where they require a moderate warm ſtove in winter; but when the plants have acquired ſtrength, they may be placed in the open air during the heat of ſummer; but it ſhould be in a ſheltered ſituation, and when the evenings grow cold in the autumn, they muſt be removed into ſhelter.

They are both propagated by ſeeds when they can be obtained, which ſhould be ſown in ſmall pots plunged into a hot-bed; they may alſo be propagated by laying down their branches, but theſe are long before they put out roots.

ELÆAGNUS. Lin. Gen. Plant. 148. Tourn. Cor. 53. tab. 489. [from 'Ελαία, an Olive, and 'Αγνὸς Vitex; becauſe this plant hath leaves like thoſe of the Chaſte-tree, and a fruit like an Olive.] Oleaſter, or wild Olive.

The Characters are,

The flower hath a bell-ſhaped empalement of one leaf, which is quadrifid, rough on the outſide, but coloured within. It hath no petals, but four ſhort ſtamina which are inſerted in the diviſions of the empalement, and are terminated by oblong proſtrate ſummits. At the bottom is ſituated a roundiſh germen ſupporting a ſingle ſtyle, crowned by a ſingle ſtigma; the germen afterward becomes an obtuſe oval fruit, with a puncture at the top, incloſing one obtuſe nut.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, from the flower having four ſtamina and one ſtyle.

The Species are,

1. Elæagnus (*Spinoſus*) aculeatus, foliis lanceolatis. *Prickly wild Olive with ſpear-ſhaped leaves.* Elæagnus Orientalis latifolius, fructu maximo. Tourn. Cor. App. 52. *Eaſtern broad-leaved wild Olive with a large fruit.*
2. Elæagnus (*Inermis*) inermis, foliis lineari-lanceolatis. *Wild Olive without thorns, and narrow ſpear-ſhaped leaves.* Elæagnus Orientalis anguſtifolius, fructu parvo olivæformi ſubdulci. Tourn. Cor. App. 52. *Eaſtern wild Olive with narrow leaves, and a ſmall, ſweet, Olive-ſhaped fruit.*
3. Elæagnus (*Latifolia*) foliis ovatis. Prod. Leyd. 250. *Wild Olive with oval leaves.* Elæagnus foliis rotundis maculatis. Burm. Pl. Zeyl. 92. *Wild Olive with round ſpotted leaves.*

The firſt and ſecond ſorts Dr. Tournefort found growing naturally in the Levant, and the firſt I take to be the common ſort, which grows naturally in Bohemia, of which I ſaw ſome trees growing in the curious garden of the late Dr. Boerhaave, near Leyden, in Holland. The leaves of this ſort are not more than two inches long, and about three quarters of an inch broad in the middle; they are white, and have a ſoft cottonny down on their ſurface; at the foot-ſtalk of every leaf, there comes out a pretty long ſharp thorn; as the leaves are placed alternate on the branches, ſo the ſpines come out on each ſide the branches; juſt below the foot-ſtalks of the leaves, they are alternately longer: the flowers are ſmall, the inſide of the empalement is yellow, and they have a ſtrong ſcent when fully open.

The ſecond ſort hath no thorns on the branches, the leaves are more than four inches long, and not half an inch broad; they are very ſoft, and have a ſhining appearance like ſattin. The flowers come out at the foot-ſtalks of the leaves, ſometimes ſingly, at other times two, and frequently three at the ſame place; the outſide of the empalement is ſilvery and ſtudded, the inſide of a pale yellow, having a very ſtrong ſcent. This flowers in July, and ſometimes the flowers are ſucceeded by fruit. This is the ſort which is moſt commonly preſerved in the Engliſh gardens.

Theſe plants may be propagated by laying down the young ſhoots in autumn, which will take root in one year, when they may be cut off from the old trees, and either tranſplanted into a nurſery for two or three years to be trained up, or into the places where they are to remain. The beſt ſeaſon for tranſplanting of theſe trees is in the latter end of February, or the beginning of March; though they may be removed at Michaelmas, provided the roots are mulched, to protect them from ſevere froſt in winter. Theſe plants ſhould be placed where they may be ſcreened from ſtrong winds, for they grow very freely, and are very ſubject to be ſplit down by the wind, if they are too much expoſed.

Theſe trees commonly grow to twelve or fourteen feet high, and when they are intermixed with other trees of the ſame growth, make a pretty diverſity; for their leaves being of a ſilver colour, are eaſily diſtinguiſhed at a diſtance.

The third ſort grows naturally at Ceylon, and in ſome other parts of India. This is pretty rare at preſent in the Engliſh gardens, but ſome years paſt there were ſeveral pretty large plants of it growing in the garden at Hampton Court. This riſes with a woody ſtem to the height of eight or nine feet, dividing into many branches, garniſhed with oval ſilvery leaves, which have ſeveral irregular ſpots of a dark colour on their ſurface; they are placed alternately on the branches, and continue all the year. The flowers I have not ſeen, though ſome of the trees at Hampton Court produced flowers, but I was not ſo lucky as to ſee them.

This ſort requires a warm ſtove to preſerve it in this country, for it is too tender to live in the open air, excepting for a ſhort time in the warmeſt part of ſummer.

The two firſt ſorts are extremely hardy, ſo are not injured by the froſt, but the trees are not of very long duration, therefore young plants ſhould be raiſed once in three or four years, to preſerve the kinds.

ELATERIUM. See MOMORDICA.

ELATINE. See LINARIA.

ELECAMPANE. See INULA.

ELEPHANTOPUS. Lin. Gen. Plant. 827. Vaill. Act. Par. 1719. Dill. Hort. Elth. 104. [of 'Ελέφας, an elephant, and Πȣ͂ς, a foot,] Elephant's foot; ſo called by Monſieur Vaillant, becauſe he ſays the under leaves of the firſt ſort ſomewhat reſemble an Elephant's foot.

The CHARACTERS are,

There are many flowers collected together in one common large involucrum which is permanent, and each empalement contains four or five florets; the florets are tubulous and hermaphrodite; they have one petal which is tongue-ſhaped; the brim is narrow, and divided into five equal parts; they have five very ſhort hairy ſtamina, terminated by cylindrical ſummits. In the bottom is ſituated an oval germen, ſupporting a ſlender ſtyle, crowned by two ſlender ſtigmas; the germen afterward becomes a ſingle compreſſed ſeed crowned with briſtles, ſitting on a placenta incloſed in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's ſeventeenth claſs, which includes the plants with floſculous flowers, whoſe florets are all hermaphrodite and fruitful.

The SPECIES are,

1. ELEPHANTOPUS (*Scaber*) foliis oblongis ſcabris. Hort. Cliff. 390. *Elephantopus with oblong rough leaves.* Elephantopus conyzæ folio. Vaill. Mem. Acad. Scien. 1719. *Elephant's foot with a Flea-bane leaf.*
2. ELEPHANTOPUS (*Tomentoſus*) foliis ovatis tomentoſis. Gron. Virg. 90. *Elephantopus with oval woolly leaves.* Elephantopus helenii folio, purpuraſcente flore. Houſt. MSS. *Elephantopus with an Elecampane leaf, and a purpliſh flower.*

The firſt ſort grows naturally in both the Indies, I have received it from ſeveral parts of America; this ſends out many oblong rough leaves, which ſpread near the ground; between theſe in the ſpring ariſes a branching ſtalk, little more than a foot high. The ſide branches are ſhort, and are generally terminated by two heads of flowers, each ſtanding upon a ſhort foot-ſtalk. The heads contain ſeveral hermaphrodite florets, included in a common involucrum, compoſed of four oval leaves, ending in acute points. The florets are of a pale purple colour. They appear in July, but are rarely ſucceeded by ſeeds in England.

The ſecond ſort grows naturally in South Carolina; the plants of this have frequently come up in the earth, which has been ſent over from thence with other plants as weeds; this hath ſeveral oval woolly leaves, four inches long, and three inches broad, growing from the root, having many tranſverſe nerves, running from the midrib to the ſides; they ſpread flat on the ground, and between theſe ariſe a ſtiff ſtalk, about a foot high, which divides into ſeveral branches, each being terminated by two flowers, which are compoſed of ſeveral florets, incloſed in a four-leaved involucrum; two of theſe leaves are alternately larger than the other. The involucrum is longer than the florets, ſo they do but juſt appear within the two larger leaves; the flowers make no appearance. They appear in July, but the ſeeds never ripen in this country.

The firſt ſort hath a perennial root, but an annual ſtalk. If this is planted in pots, and ſheltered in the winter from froſt, it may be preſerved ſeveral years, and the plants will annually flower; but the ſecond ſort ſeldom continues longer than two years.

Theſe plants are propagated by ſeeds, which ſhould be ſown on a hot-bed in the ſpring; and when the plants are come up, they muſt be tranſplanted into pots filled with freſh light earth, and plunged into a hot-bed of tanners bark, obſerving to water and ſhade them until they have taken root; then you ſhould let them have a large ſhare of freſh air in warm weather, and they will require to be frequently refreſhed with water.

ELEPHAS. See RHINANTHUS.

ELICHRYSUM. See GNAPHALIUM.

ELM. See ULMUS.

ELLISIA.

The CHARACTERS are,

The flower has a permanent empalement, compoſed of five ſmall, erect, ſpreading leaves; it is of one petal, funnel-ſhaped the length of the cup, cut into five obtuſe ſegments at top; it hath five ſtamina the length of the tube, terminated by roundiſh ſummits, and a round germen ſupporting a ſhort ſlender ſtyle, crowned by an oblong bifid ſtigma; the germen afterward becomes a roundiſh fleſhy berry with two cells, incloſing two rough ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fiſth claſs, intitled Pentandria Monogynia, the flower having five ſtamina and one ſtyle.

We know but one SPECIES of this genus, viz.

ELLISIA (*Nyctelea.*) Lin. Sp. 1662. *Tea-leaved Elliſia*

This plant grows naturally in Jamaica, where it forms a buſhy ſhrub about ſix or ſeven feet high. I have raiſed many of the plants from ſeeds, ſome of which are now four or five feet high, but have not as yet produced flowers. It ſends out many branches from the ſtem, ſo as to form a thick buſh; the branches are generally covered with a dark purple bark; the leaves alſo when the plants are expoſed in ſummer turn of the ſame colour, but after they have been ſome time removed into the ſtove, they recover their verdure again. The leaves are placed oppoſite on the branches, which are an inch and a half long, ſpear-ſhaped and indented on their edges, and have commonly two or three ſmall leaves ſitting cloſe to the branches; at the foot-ſtalks of the larger leaves, and at the ſame place, ariſes pretty long black ſpines, generally placed oppoſite toward the lower part of the branches, but upward they are alternate, and the ends of the branches are without thorns. As the plants have not as yet produced flowers in England, ſo I can give no farther account of them.

This plant may be propagated by cuttings, which if planted in ſmall pots filled with light earth, and plunged into a moderate hot-bed, covering them cloſe with a hand-glaſs any time in July, will put out roots in about two months, ſo may then be ſeparated and put into ſmall pots, plunging them again into the hot-bed to promote their taking new root, after which they ſhould be gradually inured to the open air; but the beginning of October they ſhould be removed into the dry ſtove, where, during the winter, they ſhould have a moderate warm air, in which they will thrive better than in a great heat.

When ſeeds of this plant can be procured from abroad, if they are ſown on a hot-bed the plants will riſe eaſily, and may be afterward treated in the ſame way as is directed for thoſe raiſed by cuttings.

EMERUS. Tourn. Inſt. R. H. 650. Coronilla. Lin. Gen. Plant. 789. [this name was given it by Theophraſtus, and reſtored by Cæſalpinus.] Scorpion Sena.

The Characters are,

The flower hath a very ſhort empalement of one leaf, divided into five parts which is permanent. The flower is of the butterfly kind. The tails of the petals are much longer than the empalement. The ſtandard is narrow, and ſhorter than the wings, over which it is arched. The wings are large and concave. The keel is heart-ſhaped and reflexed. There are ten ſtamina in each, one of which ſtands ſeparate, the other nine are joined; theſe are ſituated in the ſtandard. In the empalement is ſituated an oblong ſlender germen, ſupporting a ſlender ſtyle, crowned by a taper ſtigma. The germen afterward becomes a taper cylindrical pod, ſwelling in thoſe parts where the ſeeds are lodged, which are alſo cylindrical.

This genus of plants is ranged in the third ſection of Tournefort's twenty-ſecond claſs, which includes the trees and ſhrubs with a butterfly flower, whoſe leaves are placed by pairs along the midrib. Dr. Linnæus has joined this genus, and alſo the Securidacca of Tournefort to the Coronilla; but hereby the number of ſpecies are increaſed, and therefore it is much better to keep them ſeparate, as there are more eſſential differences between them, than in ſome of the other genera of this claſs which he has ſeparated.

The Species are,

1. Emerus (*Major*) caule fruticoſo, pedunculis longioribus caule angulato. *Scorpion Sena with a ſhrubby ſtalk, longer foot-ſtalks to the flowers, and angular ſtalks.* Emerus. Cæſalp. *Scorpion Sena, vulgò.*
2. Emerus (*Minor*) foliolis obcordatis, pedunculis brevioribus, caule fruticoſo. *Scorpion Sena with long heart-ſhaped leaves, ſhorter foot-ſtalks to the flowers, and a ſhrubby ſtalk.* Emerus minor. Tourn. Inſt. R. H. 650. *Leſſer Scorpion Sena.*
3. Emerus (*Herbacea*) caule erecto, herbaceo, foliolis multijugatis, floribus ſingularibus alaribus, ſiliquis longiſſimis erectis. *Scorpion Sena with an erect herbaceous ſtalk, the leaves compoſed of many pair of lobes, ſingle flowers proceeding from the ſides of the ſtalks, and very long erect pods.* Emerus ſiliquis longiſſimis & anguſtiſſimis. Plum. Cat. 19. *Emerus with very long and narrow pods.*

The firſt of theſe ſhrubs is very common in all the nurſeries near London; this riſes with weak ſhrubby ſtalks to the height of eight or nine feet, dividing into many ſlender branches, garniſhed with winged leaves, compoſed of three pair of lobes (or ſmall leaves) terminated by an odd one. The flowers come out upon long foot-ſtalks from the ſide of the branches, two or three of theſe foot-ſtalks ariſing from the ſame point; each of theſe ſuſtains two, three, or four yellow butterfly flowers; theſe appear in May, and are frequently ſucceeded by long ſlender pods, which are taper, ſwelling in thoſe parts where the ſeeds are lodged, and hang downward; theſe ſhrubs continue long in flower, eſpecially in cool ſeaſons, and frequently flower again in autumn, which renders them valuable.

The ſecond ſort riſes with many ſhrubby ſtalks like the firſt, but not more than half the height; this hath larger leaves, which are of an oblong heart-ſhape. The flowers are rather larger than thoſe of the firſt, and ſtand upon ſhorter foot-ſtalks; theſe differences hold in the plants which are raiſed from ſeeds, therefore I think they may be allowed to ſtand as diſtinct ſpecies, though there is a great likeneſs at firſt ſight in them.

The leaves of theſe ſhrubs, when fermented in a vat, in the ſame manner as is practiſed with the Indigo plants, will afford a dye, very near to that of Indigo; but whether it will anſwer the ſame purpoſes is not yet certain, or whether it may be worth cultivating for that purpoſe, either here or abroad, is what we cannot yet determine; but there is ſo great affinity between theſe plants, and thoſe of the Indigo in their generical characters, that Dr. Tournefort, and ſeveral other botaniſts, have ranged them in the ſame genus.

Theſe ſhrubs are eaſily propagated by ſowing their ſeeds (which they commonly produce in great plenty) in March, upon a bed of light ſandy earth, obſerving to keep the bed clear from weeds; and in very dry weather the bed muſt often be refreſhed with water, which ſhould be given carefully, leſt the ſeeds ſhould be waſhed out of the ground by haſty watering. When the plants are come up, they muſt be kept clean from weeds, and in very dry weather, if they are watered, it will promote their growth; the Michaelmas following (if the plants have thriven well) you may draw out the largeſt, which may be tranſplanted into a nurſery, at three feet diſtance row from row, and one foot aſunder in the rows. This will give room to thoſe plants which are left to grow in the ſeed-bed, in which place they may remain another year, when they will alſo be fit to tranſplant into a nurſery, where they ſhould be two years, when they will be fit to plant out, where they are to remain for good; in doing of which, you ſhould be careful in taking them up, not to break or wound the roots, nor ſhould they remain too long in the nurſery before they are tranſplanted, for they are ſubject to ſhoot downright roots, which, when cut off, oftentimes proves the death of the tree. In all other reſpects it muſt be treated like other flowering ſhrubs, among which this is commonly ſold at the nurſeries. It may alſo be propagated by laying down the tender branches, which will take root in about a year's time, and may then be tranſplanted into a nurſery, and managed in the ſame manner as the ſeedling plants.

The third ſort grows naturally in the Weſt-Indies, where Plumier firſt diſcovered it in the French ſettlements; but it was found growing in plenty at La Vera Cruz, in New Spain, by the late Dr. Houſtoun, who ſent me the ſeeds, which ſucceeded in the Chelſea garden, where the plants flowered, but did not perfect their ſeeds, and the plants being annual, the ſpecies was loſt here. This riſes with a round herbaceous ſtalk three feet high, which is garniſhed at each joint with one long winged leaf, compoſed of about twenty pair of lobes, terminated by an odd one; theſe have obtuſe points, and are of a deep green. The flowers come out ſingly from the ſide of the ſtalk, immediately above the foot-ſtalk of the leaves, ſtanding upon ſlender foot-ſtalks two inches long; they are larger than thoſe of either of the former ſorts, and are of a pale yellow colour; theſe are ſucceeded by ſlender compreſſed pods, which are more than ſix inches long, having a border on each ſide, and a ſwelling where each ſeed is lodged.

This is an annual plant, whoſe ſeeds muſt be ſown upon a hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each planted into a ſeparate ſmall pot filled with light kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, ſhading them from the ſun until they have taken new root, then they muſt be treated in the ſame manner as other exotic plants from thoſe warm countries. If theſe plants are brought forward in the ſpring, and kept under a deep frame in a tan-bed, or plunged into the bark-bed in the ſtove, when they are grown too tall to remain under common frames, they will ripen ſeeds in England; for thoſe ſeeds which I received did not arrive here till May, and yet thoſe plants flowered well in Auguſt; but the autumn coming on ſoon after, prevented their perfecting ſeeds, and that part of the ſeed which I reſerved till the next year did not grow.

EMPETRUM. Lin. Gen. Plant. 977. Tourn. Inſt. R. H. 579. tab. 421. [Ἔμπετρον, of ἐν, in, and πέτρα, *Gr.* a rock or ſtone, becauſe this tree grows in ſtony places.] Black-berried Heath.

The Characters are,

It hath male and female flowers on different plants; the male flowers have a three-pointed empalement, which is permanent; they have three oblong petals, which are narrow at their baſe, and three long hanging ſtamina which are

are hairy, terminated by ſhort two-pointed ſummits, which ſtand erect. The female flowers have the ſame empalement and petals as the male, but no ſtamina. In the center is ſituated a depreſſed germen, ſupporting nine reflexed ſpreading ſtigma. The germen afterward becomes a depreſſed round berry of one cell, incloſing nine ſeeds placed circularly.

This genus of plants is ranged in the third ſection of Linnæus's twenty-ſecond claſs, which includes thoſe plants whoſe male and female flowers grow on ſeparate plants, and the male flowers have three ſtamina.

We have but one Species of this genus in England, viz.

Empetrum (*Nigrum*) procumbens. Hort. Cliff. 470. *Trailing Berry-bearing Heath.* Empetrum montanum, fructu nigro. Tourn. Inſt. 579. *Black-berried Heath, Crow berries, Crake berries.*

This little ſhrub grows wild upon the mountains of Staffordſhire, Derbyſhire, and Yorkſhire, and is ſeldom propagated in gardens unleſs for variety ſake; but it may be cultivated in ſhady places, and will thrive very well in gardens, where the ſoil is ſtiff. The plants ſhould be procured from the places where they grow naturally, for the ſeeds remain a year in the ground before they vegetate, and afterward are very ſlow in their growth, ſo they are not worth the trouble of cultivating from ſeeds. If the plants are planted on a moiſt boggy ſoil in autumn, they will get roots in the winter, and will require no farther care than to clear them from weeds, provided they have a moiſt ſoil, otherwiſe they will require to be frequently watered; for theſe low ſhrubs commonly grow upon the tops of wild mountains, where the ſoil is generally peaty, and full of bogs. The heath cocks feed much upon the berries of this plant; ſo that wherever there is plenty of theſe low ſhrubs, there are commonly many of theſe fowls to be found.

EMUSCATION, the clearing a tree of moſs, *Lat.*

ENUCLEATION, a taking out the nut or kernel of any fruit, *Lat.*

ENULA CAMPANA. See Inula.

EPHEDRA. Lin. Gen. Plant. 1007. Tourn. Inſt. 663. tab. 477. Shrubby Horſe-Tail, vulgò.

The Characters are,

It hath male and female flowers in different plants; the male flowers are collected in katkins, which are ſcaly; under each ſcale is a ſingle flower; theſe have no petals, but ſeven ſtamina, which are joined in form of a column, and are terminated by roundiſh ſummits. The female flowers have an oval perianthium, compoſed of five ſeries of leaves, which alternately lie over the diviſions of the lower range; theſe have no petals, but have two oval germen ſitting upon the perianthium, ſupporting ſhort ſtyles, crowned by ſingle ſtigma. The germen afterward turn to oval berries, each having two ſeeds.

This genus of plants is ranged in the twelfth ſection of Linnæus's twenty-ſecond claſs, intitled Diœcia Monadelphia, the plants of this claſs and ſection having male flowers on different plants from the female, and their ſtamina join in form of a column.

We have but one Species of this genus in England, viz.

Ephedra (*Diſtachia*) pedunculis oppoſitis, amentis geminis. Hort. Cliff. 465. *Shrubby Horſe-Tail with oppoſite foot-ſtalks, and twin katkins.* Ephedra maritima minor. Tourn. *Leſſer Sea Horſe-Tail.*

This is a low ſhrubby plant, which grows naturally upon the rocks by the ſea in the ſouth of France, in Spain, and Italy; it is alſo preſerved in ſeveral gardens for the ſake of variety, but has little beauty. This hath a low ſhrubby ſtalk, which puts out a few ſhort branches, riſing about two feet high, which have many protuberant joints, at which come out ſeveral narrow ruſhy leaves, like thoſe of the Horſe-Tail, which continue green all the year, but the plants rarely flower in this country.

It may be propagated by offſets, which the plants ſend forth in great plenty; for the roots creep under ground, and ſend forth ſuckers, which may be taken off to tranſplant in the ſpring. They love a pretty moiſt ſtrong ſoil, and will endure the cold of our ordinary winters very well in the open air. Some of theſe plants were formerly preſerved in pots, and were houſed in winter, but by later experience they are found to thrive better in the full ground.

EPHEMERUM. See Tradescantia.

EPIDENDRUM. Lin. Gen. 1016. Vanilla.

There are near thirty ſpecies of this genus, which grow naturally upon trees in Africa and both Indies; but as the plants cannot, by any art yet known, be cultivated in the ground, it would be to little purpoſe the enumerating of them here; though could the plants be brought to thrive by culture, many of them produce very fine flowers of uncommon forms. I had three ſpecies of them ſent me from America, which were ſtripped from the trees on which they grew; theſe I planted with care in pots, which were placed in a ſtove, where they came ſo far as to ſhew their flowers, but the plants ſoon after periſhed.

EPIGÆA. Lin. Gen. Plant. 486. Memecylum. Mitch. 13. Trailing Arbutus.

The Characters are,

The flower hath a double empalement, which is permanent; the outer is compoſed of three, and the inner of one leaf, divided at the top into five parts. The flower is of the ſalver ſhape, with one petal, having a cylindrical tube, which is longer than the empalement, and hairy within. The brim is cut into five parts, which ſpread open. It hath ten ſlender ſtamina the length of the tube, which are fixed to the baſe of the petal, and are terminated by oblong ſummits. In the center is ſituated a globular hairy germen, crowned by an obtuſe quinquefid ſtigma. The germen afterward becomes a depreſſed, half globular, five-cornered fruit, having five cells, opening with five valves, containing ſeveral ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, the flowers having ten ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Epigæa. Lin. Gen. Plant. 486. Trailing Arbutus.

This plant grows naturally in North America, from whence it has been introduced to the Engliſh gardens. It is a low plant, with a trailing ſhrubby ſtalk, which puts out roots at the joints, and when in a proper ſoil and ſituation, multiplies very faſt. The ſtalks are garniſhed with oblong rough leaves which are waved on their edges. The flowers are produced at the end of theſe branches in looſe bunches; theſe are white, and divided at the top into five acute ſegments, which ſpread open in form of a ſtar. It flowers in July, but doth not produce fruit in England.

The plants are eaſily propagated by their trailing ſtalks, which put out roots at the joints, ſo may be cut off from the old plant, and placed in a ſhady ſituation and a moiſt ſoil: the beſt time for this is in autumn, that the plants may be well rooted before the ſpring. If the winter ſhould prove very ſevere, it will be proper to lay a few dried leaves, or ſome ſuch light covering over them, which will prevent their being injured by froſt; and after they are well rooted, they will require no farther care but to keep them clean from weeds.

EPILOBIUM. Lin. Gen. Plant. 426. Chamænerion. Tourn. R. H. 302. tab. 157. Willow Herb, or French Willow.

The Characters are,

The empalement of the flower is compoſed of four oblong pointed leaves, which are coloured. The flower hath four bordered petals which ſpread open, and eight ſtamina which are alternately ſhorter, terminated by oval compreſſed ſummits. Below the flower is ſituated a long cylindrical germen, ſupporting a ſlender ſtyle, crowned by an obtuſe quadrifid ſtigma. The germen afterward becomes a long, cylindrical, furrowed capſule with five cells, filled with oblong ſeeds, crowned with down.

This genus of plants is ranged in the firſt ſection of Linnæus's eighth claſs, intitled Octandria Monogynia, the flower having eight ſtamina and one ſtyle.

The Species are,

1. Epilobium (*Anguſtifolium*) foliis ſparſis lineari-lanceolatis, floribus inæqualibus. Lin. Sp. 493. *Epilobium with linear ſpear-ſhaped leaves which are placed thinly, and unequal flowers.* Chamænerion latifolium vulgare. Tourn. Inſt. R. H. 302. *Common broad-leaved Willow Herb, or French Willow.*
2. Epilobium (*Hirſutum*) foliis oppoſitis lanceolatis ſerratis decurrenti-amplexicaulibus. Lin. Hort. Cliff. 145. *Epilobium with oppoſite ſpear-ſhaped leaves, which are ſawed on their edges.* Chamænerion villoſum, magno flore purpureo. Tourn. Inſt. R. H. 303. *Hoary Willow Herb with a large flower, commonly called Codlins and Cream.*

There are ſeveral other ſpecies of this genus, ſome of which grow naturally in ſhady woods and moiſt places in moſt parts of England, where they are often very troubleſome weeds, therefore are ſeldom admitted into gardens, ſo I ſhall not trouble the reader with their diſtinctions.

The firſt ſort here mentioned was formerly planted in gardens for the beauty of its flowers; but as it uſually ſpreads far by the creeping roots, whereby it over-runs all the neighbouring plants, it has been generally caſt out of moſt gardens: however, in ſome low moiſt places, or in great ſhade, if there was a place aſſigned for this plant, it will make a good appearance when it is in flower, and theſe flowers are very proper to cut for baſons to adorn chimnies in the ſummer ſeaſon. This uſually grows about four feet high, with ſlender ſtiff branches, which are beſet with leaves, reſembling thoſe of the Willow, from whence it had the name of Willow Herb, or French Willow. On the upper part of the ſtalks the flowers are produced in a long ſpike or thyrſe, which are of a fine Peach colour, and, if the ſeaſon is not very hot, they will continue near a month in beauty. This ſort is found growing wild in divers parts of England, but ſeveral botaniſts have ſuppoſed it was only found in ſuch places where the plants had been caſt out of gardens; however, I think it muſt be allowed to be a native of this country, ſince it is found in great plenty in woods at a great diſtance from any habitation, particularly in Charlton foreſt, and ſeveral other woods in Suſſex. It is a great creeper at the root, ſo may be eaſily propagated.

There is a variety of this with white flowers, which is planted in gardens, but differs from it only in the colour of the flower; however, ſome perſons are fond of propagating theſe varieties, for which reaſon I mentioned it here.

The ſecond ſort is found wild by the ſide of ditches and rivers in many parts of England. This plant grows about three feet high, and produces its flowers on the top of the ſtalks; but theſe are much leſs beautiful than thoſe of the firſt, and the plant being a great rambler at the root, is ſeldom admitted into gardens. The leaves of this plant being rubbed, emit a ſcent like ſcalded Apples, from whence ſome have given the name of Codlins and Cream to this plant.

EPIMEDIUM. Lin. Sp. Plant. 138. Tourn. Inſt. R. H. 232. tab. 117. Raii Meth. Plant. 129. Barrenwort.

The Characters are,

The flower hath a three-leaved empalement which falls off. It hath four obtuſe oval fruit, which are concave, and ſpread open, and four nectariums which are cup-ſhaped, obtuſe at the bottom, and as large as the petals. It hath four ſtamina, terminated by oblong, erect, bilocular ſummits. The oblong germen is ſituated at the bottom, ſupporting a ſhort ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes an oblong pointed pod, with one cell, opening with two valves, incloſing many oblong ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flower having four ſtamina and one ſtyle.

We know but one Species of this genus, viz.

1. Epimedium (*Alpinum.*) Hort. Cliff. 37. *Alpine Barrenwort.*

This plant hath a creeping root, from which ariſe many ſtalks about nine inches high, divided at the top into three, each of which is again divided into three ſmaller; upon each of theſe ſtands a ſtiff heart-ſhaped leaf, ending in a point, of a pale green on the upper ſide, but gray on the under. A little below the firſt diviſion of the ſtalk comes out the foot-ſtalk of the flowers, which is near ſix inches long, dividing into ſmaller, each of theſe ſuſtaining three flowers; theſe are compoſed of four leaves, placed in form of a croſs; they are of a reddiſh colour, with yellow ſtripes on the border. In the center of the flower ariſes the ſtyle, ſituated upon the germen, which afterward turns to a ſlender pod, containing many oblong ſeeds. It flowers in May, and the leaves decay in autumn. The roots, if planted in a ſhady border, ſhould be every year reduced, ſo as to keep them within bounds, otherwiſe it will ſpread its roots and interfere with the neighbouring plants. It grows naturally on the Alps, but I received ſome plants of it which were found growing naturally in a wood in the North of England.

EPIPHYLLOSPERMOUS PLANTS [of ἐπὶ, upon, Φύλλον, a leaf, and Σπέρμα, *Gr.* ſeed,] ſuch plants as bear their ſeeds on the back of their leaves, the ſame as capillaries.

EQUINOCTIAL, ÆQUINOCTIAL [of equus, equal, and nox, *Lat.* night.] A great and immoveable circle of the ſphere, under which the equator moves in its diurnal motion.

The equinoctial, or equinoctial line, is ordinarily confounded with the equator; but there is a difference, the equator being moveable, and the equinoctial unmoveable, and the equator drawn about the convex ſurface of the ſphere, but the equinoctial on the concave ſurface of the Magnus Orbis.

The equinoctial is conceived, by ſuppoſing a ſemidiameter of the ſphere, produced through a point of the equator, and there deſcribing a circle on the immoveable ſurface of the Primum Mobile, by the rotation of the ſphere about its axis.

Whenever the ſun comes to this circle, in his progreſs through the ecliptic, it makes equal day and night all round the globe; as then ariſing due eaſt, and ſetting due weſt, which he never does at any other times of the year.

The people who live under this circle, have their days and nights conſtantly equal; and the ſun is in their zenith at noon, and caſts no ſhadow.

EQUINOXES are the times when the ſun enters into the equinoctial points, which are the two points where the equator and ecliptic interſect each other; the one being in the firſt point of Aries, called the vernal equinox; and the other in the firſt point of Libra, called the autumnal equinox.

So the equinoxes happen when the ſun is in the equinoctial circle, when, of conſequence, the days are equal to the nights throughout the world, which is the caſe twice a year, viz. about the 21ſt of March, and the 22d of September; the firſt of which is the vernal, and the ſecond the autumnal equinox.

EQUISETUM [of equus, a horſe, and ſeta, a briſtle, becauſe the leaves and branches repreſent the briſtles or hair of a horſe's main or tail. It is by the Greeks called Ἵππουρις, of Ἵππος, a horſe, and Οὐρὰ, a tail; and hippoſeta, of ἵππος and ſeta.] Horſe-Tail.

There are ſeveral ſpecies of this plant, which are found in England, on the ſides of ditches, or in ſhady woods; but as they are plants which are never cultivated in gardens, I ſhall paſs them over in this place.

ERANTHEMUM. See Adonis.

ERICA. Lin. Gen. Plant. 435. Tourn. Inſt. R. H. 602. tab. 373. [Ἐρείκη, of ἐρείκω, or ἐρίκω, *Gr.* to break, becauſe this plant is ſaid to have the virtue of breaking the ſtone in the bladder.] Heath; in French, *Bruyere.*

The Characters are,

The flower hath a coloured permanent empalement of four oval

oval erect leaves. It hath one ſwelling petal, which is erect and quadrifid, and eight hairy ſtamina, which are fixed to the receptacle, and terminated by bifid ſummits. In the bottom is ſituated the roundiſh germen, ſupporting a declining ſtyle, which is longer than the ſtamina, crowned by a four-cornered ſtigma. The germen afterward becomes a round capſule, having four cells, which are filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's eighth claſs, intitled Octandria Monogynia, the flower having eight ſtamina and one ſtyle.

The Species are,

1. Erica (*Vulgaris*) antheris bicornibus incluſis, corollis inæqualibus, campanulatis mediocribus foliis oppoſitis ſagittatis. Lin. Sp. Plant. 352. *Heath with two horns including the ſummits, bell-ſhaped unequal petals, and middling arrow-pointed leaves placed oppoſite.* Erica vulgaris glabra. C. B. 485. *Common ſmooth Heath.*

2. Erica (*Herbacea*) antheris bicornibus incluſis campanulatis mediocribus ſecundis, foliis ternis triquetris patulis. Lin. Sp. Plant. 500. *Heath with a horned ſummit, a bell-ſhaped petal, and five narrow ſpreading leaves.* Erica foliis coridis, multiflora. J. B. vol. 1. p. 356. *Pine-leaved Heath with many flowers.*

3. Erica (*Cinerea*) antheris bicornibus incluſis, corollis ovatis racemoſis, foliis ternis glabris linearibus. Lin. Sp. Plant. 352. *Heath with two horns including the ſummits, oval branchy petals, and three long, narrow, ſmooth leaves.* Erica humilis, cortice cinereo, arbuti flore. C. B. P. 486. *Dwarf Heath with an Aſh-coloured bark, and Strawberry-tree flower.*

4. Erica (*Ciliaria*) antheris ſimplicibus incluſis, corollis ovatis irregularibus, floribus ternoracemoſis, foliis ternis ciliatis. Lœfl. Epiſt. 2. p. 9. Lin. Sp. Plant. 354. *Heath with ſingle ſummits, oval irregular petals, triple branching flowers, and hairy leaves placed by threes.*

5. Erioa (*Arborea*) antheris bicornibus incluſis, corollis campanulatis longioribus, foliis quaternis patentiſſimis, caule ſubarboreo tomentoſo. Lin. Sp. 502. *Tree Heath, whoſe antheræ are included in two horns, a longer bell-ſhaped flower, and four ſpreading leaves at each joint.*

The four firſt ſorts grow wild upon barren uncultivated places in divers parts of England; but notwithſtanding their commonneſs, yet they deſerve a place in ſmall quarters of humble flowering ſhrubs, where, by the beauty and long continuance of their flowers, together with the diverſity of their leaves, they make an agreeable variety.

Theſe are ſeldom propagated in gardens, and ſo not to be had from the nurſeries, but may be taken up, with a ball of earth to their roots, from the natural place of their growth in autumn, and may be tranſplanted into the garden. The ſoil where they are planted ſhould not be dunged, nor ſhould you beſtow any other culture on them than clearing them from weeds; for the leſs the ground is dug, the better theſe will thrive, for they commonly ſhoot their roots near the ſurface, which, in digging, are ſubject to be hurt, whereby the plant is often deſtroyed; theſe may alſo be propagated by ſeeds, but this being a tedious method, the other is much preferable to it.

The fifth ſort grows naturally at the Cape of Good Hope, and alſo in great plenty in Portugal, where it riſes with a ſtrong ligneous ſtem to the height of eight or ten feet, ſending out many branches the whole length, garniſhed with narrow leaves, four coming out from the ſame point; the flowers are produced between the leaves on the upper part of the branches; they are white, with a bluſh of red on their outſide; theſe appear in May, but are not ſucceeded by ſeeds in England.

This plant will live in the open air in England, provided it is planted in a dry ſoil and a warm ſituation, but is generally kept in pots and houſed in winter; however, the plants ſo managed, do not thrive or flower ſo well as thoſe in the full ground, therefore it is much better to be at the trouble of ſheltering the plants in the ground in winter, than to keep them in pots. It is with difficulty propagated here, which is done by laying down the young ſhoots, though theſe are often two years before they put out roots: others plant the young ſlips or cuttings into pots filled with light earth, covering them cloſe with a bell-glaſs, and ſhading them from the ſun; where this is ſkilfully practiſed, the cuttings will put out roots, and make better plants than the layers.

ERICA BACCIFERA. See Empetrum.

ERIGERON. Lin. Gen. Plant. 855. Senecionis. Sp. Dill. Conyzella. Dill. Groundſel.

The Characters are,

It hath a compound radiated flower, compoſed of many hermaphrodite florets which form the diſk, and female half florets which make the rays; theſe are contained in one oblong ſcaly empalement. The hermaphrodite florets are funnel-ſhaped, and cut at the top into five parts; theſe have five ſhort hairy ſtamina, terminated by cylindrical ſummits; they have a ſmall germen, crowned with down, which is longer than the petal. Upon the germen ſits a ſlender ſtyle the length of the down, crowned by two oblong ſtigmas; the germen afterward becomes a ſmall oblong ſeed, crowned with long down. The female half florets, which compoſe the rays, have one ſide of their petals ſtretched out like a tongue; theſe have no ſtamina, but a ſmall downy germen, ſupporting a ſlender ſtyle, which is hairy, crowned by two ſlender ſtigmas. The germen afterward becomes a ſeed like the hermaphrodite florets.

This genus of plants is ranged in the ſecond ſection of Linnæus's nineteenth claſs, which includes the plants with a compound flower, compoſed of hermaphrodite and female flowers, which are both fruitful. To this genus Dr. Linnæus has added ſeveral ſpecies of Conyza and Aſter of former botaniſts.

The Species are,

1. Erigeron (*Viſcoſum*) pedunculis unifloris lateralibus foliis lanceolatis denticulatis calycibus ſquarroſis, corollis radiatis. Hort. Upſal. 258. *Groundſel with one flower on a foot-ſtalk, proceeding from the ſide of the ſtalk, ſpear-ſhaped leaves, and a rough empalement.* Conyza mas Theophraſti, major Dioſcoridis. C. B. P. 265. *Male Fleabane of Theophraſtus, and greater Fleabane of Dioſcorides.*

2. Erigeron (*Acre*) pedunculis alternis unifloris. Hort. Cliff. 407. *Groundſel with alternate foot-ſtalks having one flower.* Conyza cærulea acris. C. B. P. 265. *Blue acrid Fleabane.*

3. Erigeron (*Bonarienſe*) foliis baſi revolutis. Lin. Sp. Plant. 863. *Groundſel whoſe leaves are curved at their baſe.* Senecio Bonarienſis purpuraſcens, foliis imis coronopi. Hort. Elth. 344. tab. 257. *Purpliſh Groundſel of Buenos Ayres, with under leaves like Hartſhorn Plantain.*

4. Erigeron (*Canadenſe*) caule floribuſque paniculatis. Hort. Cliff. 407. *Groundſel with a paniculated ſtalk and flowers.* Virga aurea Virginiana annua. Zan. Hiſt. 205. *Annual Virginia Golden Rod.*

5. Erigeron (*Alpinum*) caule ſubbifloro, calyce ſubhirſuto. Lin. Sp. Plant. 864. *Groundſel with two flowers on a ſtalk, and hairy empalements.* Conyza cærulea Alpina. C. B. P. 265. *Blue Alpine Fleabane.*

6. Erigeron (*Graveolens*) ramis lateralibus multifloris, foliis lanceolatis integerrimis, calycibus ſquarroſis. Amœn. Acad. 4. p. 290. *Groundſel with many flowers on the ſide of the ſtalks, entire ſpear-ſhaped leaves, and rough empalements.* Virga aurea minor, foliis glutinoſis & graveolentibus.

7. Erigeron (*Fœtidum*) foliis lanceolato-linearibus retuſis, floribus corymboſis. Lin. Sp. 1213. *Groundſel with linear ſpear-ſhaped leaves, and flowers in a corymbus.* Senecio Africanus folio retuſo. Herm. 661.

The firſt ſort grows naturally in the ſouth of France, and in Italy. This hath a perennial root, from which ariſe ſeveral upright ſtalks near three feet high, garniſhed with oblong oval leaves which are hairy, and ſit cloſe to the ſtalk; they are placed alternate, and are four inches long, and two broad in the middle; theſe in warm weather ſweat out a clammy juice. The flowers are produced ſingle upon pretty long foot-ſtalks; ſome ariſing from the ſide of the ſtalk, and others terminate it; they are yellow, and have an agreeable odour. They flower in July, and the ſeeds ripen in autumn.

This plant is propagated by ſeeds, which, if ſown in autumn, will more certainly ſucceed than thoſe which are ſown in the ſpring. When the plants come up, they ſhould be thinned if they are too cloſe, and kept clean from weeds till autumn, when they ſhould be tranſplanted where they are to remain. They delight in a dry ſoil and a ſunny expoſure. The ſecond year the plants will flower and perfect their ſeeds, but the roots will continue ſeveral years, and annually produce their flowers and ſeeds.

The next four ſorts are preſerved in botanic gardens for the ſake of variety, but are ſeldom admitted into gardens for pleaſure. The fifth ſort is a perennial plant, which grows naturally on the Alps, and may be propagated by ſeeds in the ſame manner as the firſt ſort, but ſhould have a ſhady ſituation and a moiſt ſoil.

The others are annnual plants, which, if once admitted into a garden, and ſuffered to ſcatter their ſeeds, will become very troubleſome weeds there.

The ſixth ſort riſes with ſtiff ſtalks three feet high, garniſhed with narrow ſpear-ſhaped leaves; the flowers are yellow, and are produced in cloſe bunches from the ſide of the ſtalk toward the top; theſe appear in July, and in warm ſeaſons are ſucceeded by ſeeds in England.

It may be propagated by cutting the ſtalk in proper lengths, which, if planted in a ſhady border, and duly watered, will put out roots; and the following autumn, theſe may be taken up and planted in the borders of the flower-garden.

The ſeventh ſort grows naturally in Africa: the roots of this ſend up five or ſix upright ſtalks near four feet high, cloſely garniſhed with linear ſpear-ſhaped leaves which are hairy; the ſtalks are terminated by pretty large bunches of yellow flowers, formed in a corymbus. Theſe appear in October, and frequently continue more than two months, which renders the plant more valuable.

This is too tender to thrive in the open air in this country, ſo the plants ſhould be kept in pots; and if in the winter they are placed in a common frame, where they may have a large ſhare of free air in mild weather, and ſcreened from hard froſts, they will thrive better than with tender treatment. It is eaſily propagated by cuttings, which, if planted in May, will readily put out roots, and the young plants will flower the autumn following.

ERINUS. Lin. Gen. Plant. 689. Ageratum. Tourn. Inſt. R. H. 651. tab. 422.

The CHARACTERS are,

The flower hath a permanent empalement, compoſed of five leaves, which are equal; it hath one petal which is tubulous, and of the ringent kind, cut into five equal ſegments, which ſpread open, three ſtanding upward from the upper lip, and two turn downward. It hath four ſtamina ſituated within the tube, two of which are a little longer than the other, terminated by ſmall ſummits. In the bottom of the tube is ſituated the oval germen, ſupporting a ſhort ſtyle, crowned by a head-ſhaped ſtigma. The germen afterward becomes an oval capſule, covered by the empalement, having two cells filled with ſmall ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, which includes thoſe plants whoſe flowers have two long and two ſhort ſtamina, and their ſeeds growing in a capſule. Tournefort has it in his appendix, but it ſhould be placed in his third claſs, and the fifth ſection, which contains the plants with an anomalous tubulous flower of one leaf.

The SPECIES are,

1. ERINUS (*Alpinus*) floribus racemoſis. Lin. Sp. Plant. 630. *Erinus with branching flowers.* Ageratum ſerratum, Alpinum, glabrum, flore purpuraſcente. Tourn. R. H. 651. *Smooth ſawed Alpine Ageratum, having a purpliſh flower.*
2. ERINUS (*Tomentoſus*) tomentoſus, caulibus procumbentibus, floribus ſeſſilibus axillaribus. *Woolly Erinus with trailing ſtalks, and flowers ſitting cloſe to their ſides.* Ageratum Americanum procumbens, gnaphalii facie, floribus ad foliorum nodos. Houſt. MSS. *Trailing American Ageratum with the appearance of Cudweed, and flowers growing at the knots of the leaves.*
3. ERINUS (*Americanus*) caule erecto, foliis lanceolatis oppoſitis, floribus laxè ſpicatis terminalibus. *Erinus with an upright ſtalk, ſpear-ſhaped leaves placed oppoſite, and flowers growing in looſe ſpikes, terminating the ſtalks.* Ageratum Americanum erectum ſpicatum, flore purpureo. Houſt. MSS. *Upright American Ageratum with ſpikes of purple flowers.*
4. ERINUS (*Fruteſcens*) caule erecto fruticoſo, foliis ovato-lanceolatis ſerratis, alternis, floribus axillaribus. *Erinus with a ſhrubby erect ſtalk, oval, ſpear-ſhaped, ſawed leaves placed alternate, and flowers on the ſides of the ſtalk.* Ageratum fruteſcens, foliis dentatis latioribus, villoſum. Houſt. MSS. *Shrubby hoary American Ageratum with broad indented leaves.*
5. ERINUS (*Verticillatus*) caule ramoſo procumbente, foliis ovatis ſerratis glabris oppoſitis, floribus verticillatis. *Erinus with a branching trailing ſtalk, oval, ſmooth, ſawed leaves placed oppoſite, and flowers growing in whorls round the ſtalks.* Ageratum Americanum procumbens, foliis ſubrotundis ſerratis glabris. Houſt. MSS. *Trailing American Ageratum with roundiſh, ſmooth, ſawed leaves.*
6. ERINUS (*Procumbens*) caulibus procumbentibus, foliis ovatis glabris, floribus ſingulis alaribus, pedunculis longioribus. *Erinus with trailing ſtalks, oval ſmooth leaves, and ſingle flowers on the ſides of the ſtalks, having longer foot-ſtalks.* Ageratum Americanum, procumbens, glabrum, floribus luteis, longis pediculis inſidentibus. Houſt. MSS. *Smooth trailing American Ageratum, with yellow flowers ſitting upon long foot-ſtalks.*

The firſt ſort grows naturally upon the Alps and Helvetian mountains: this is a very low plant, whoſe leaves lie cloſe to the ground, growing in cloſe tufts; they are about half an inch long, and one eighth of an inch broad, ſawed on their edges, and of a dark green; between theſe ariſes the flower-ſtalk, which is ſcarce two inches high, ſupporting a looſe bunch of purple flowers, which ſtand erect. Theſe appear in May, and ſometimes are ſucceeded by ripe ſeeds in July.

It is propagated by parting the roots; the beſt time for this is in autumn; they muſt have a ſhady ſituation and a loamy ſoil without dung, for in rich earth theſe plants are very ſubject to rot.

The ſecond ſort was ſent me by the late Dr. Houſtoun from La Vera Cruz, where he found it growing naturally. This ſends out ſeveral trailing ſtalks about ſix inches long, which are cloſely garniſhed with ſmall oval leaves, placed on every ſide; they are very white and woolly, and at the joints juſt above the leaves come out the flowers, ſitting very cloſe to the ſtalks; theſe are white, and are ſucceeded by round capſules, having two cells, filled with ſmall ſeeds: this plant has great reſemblance at a diſtance to the Sea Cudweed.

The third ſort was diſcovered by Dr. Houſtoun, in the ſame country with the former: this hath an upright ſtalk two feet high, garniſhed with ſpear-ſhaped leaves placed oppoſite; and toward the top of the ſtalk is produced two ſmaller branches placed oppoſite, which ſtand erect; and theſe, as alſo the middle ſtalk, are terminated by looſe ſpikes of purple flowers, which are ſucceeded by oval ſeed-veſſels, filled with ſmall ſeeds.

The fourth ſort riſes with a ſhrubby ſtalk about four feet high, dividing into ſeveral ſmall branches, which are hairy; theſe are garniſhed with oval ſpear-ſhaped leaves, deeply ſawed on their edges; they are placed alternate, and have pretty long foot-ſtalks. The flowers come out from the ſide of the ſtalks, ſometimes ſingle, at other times two or three at a joint, ſitting cloſe to the ſtalks; they are white, and are ſucceeded by round ſeed-veſſels, filled with ſmall ſeeds.

The fifth ſort ſends out many trailing ſmooth ſtalks, which branch out very much on every ſide; they grow about ſeven or eight inches long, and are garniſhed with ſmall oval leaves placed oppoſite. The flowers come out in whorls, ſitting very cloſe to the ſtalks; they are white, and make but little appearance; theſe are ſucceeded by round capſules, filled with ſmall ſeeds.

The ſixth ſort ſends out ſeveral trailing ſtalks about ſix inches long, which divide into many ſmaller branches; theſe are garniſhed with ſmall oval leaves, ſtanding oppoſite. The flowers come out ſingly from the ſide of the ſtalk; they are of a bright yellow, and ſtand on long ſlender foot-ſtalks; theſe are ſucceeded by oval ſeed-veſſels, filled with ſmall ſeeds.

The fourth ſort is a perennial ſhrubby plant, which will continue ſeveral years, if kept in a warm ſtove; but the ſecond, third, fifth, and ſixth ſorts are annual, decaying ſoon after they have perfected their ſeeds.

Theſe are propagated by ſeeds, which ſhould be ſown in pots filled with light earth, and plunged into a moderate hot-bed, where ſometimes the plants will come up in five or ſix weeks, and at other times the ſeeds do not vegetate till the following ſpring; this happens frequently when the ſeeds have been kept long after they were gathered. When the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with light earth, not too rich with dung, and then plunged into a hot-bed of tanners bark. When they have taken new root, they ſhould be treated in the ſame way as other plants from thoſe countries, by admitting proper air to them at all times when the weather is warm, and frequently refreſhing them with water: with this management the annual ſorts will flower in July and Auguſt, and frequently ripen their ſeeds in autumn, if the plants are brought forward early in the ſpring, otherwiſe the winter will come on before their ſeeds ripen.

The ſhrubby kind muſt be placed in the bark-ſtove in autumn, and during the winter the plants ſhould be frequently refreſhed with water, but it muſt not be given them in large quantities, nor too often repeated in cold weather, for moiſture will then deſtroy them; the ſecond year the plants will flower and perfect their ſeeds.

ERIOCEPHALUS. Dill. Hort. Elth. 110. Lin. Gen. Plant. 890.

The Characters are,

It hath a radiated flower, compoſed of female half florets which form the rays, and hermaphrodite florets, which form the diſk; theſe are included in one common ſcaly empalement. The hermaphrodite florets are funnel-ſhaped, and cut into five parts at the brim, which ſpread open; theſe have five ſhort hairy ſtamina, terminated by cylindrical ſummits; they have a ſmall naked germen, ſupporting a ſingle ſtyle, crowned by a pointed ſtigma; theſe are barren. The female florets have their petals ſtretched out on one ſide like a tongue, which is divided at the end into three ſmall lobes; theſe have no ſtamina, but an oval naked germen, with a ſingle ſtyle, crowned by an inflexed ſtigma; theſe have one naked ſeed, ſitting on the naked plain receptacle.

This genus of plants is ranged in the fourth ſection of Linnæus's nineteenth claſs, which includes thoſe plants with compound flowers, whoſe hermaphrodite florets are barren, and the female half florets are fruitful.

We know but one Species of this genus, viz.

Eriocephalus (*Africanus.*) Lin. Sp. Plant. 926. We have no proper title for this in Engliſh. Eriocephalus ſempervirens, foliis faſciculatis & digitatis. Hort. Elth. 132. *Evergreen Eriocephalus with fingered leaves growing in bunches.*

This plant hath a ſhrubby ſtalk, which riſes from four to ſix feet high, putting out many ſide branches the whole length, cloſely garniſhed with woolly leaves, which come out in cluſters; ſome of theſe are taper and entire, others are divided into three or five parts, which ſpread open like a hand; they have a ſtrong ſmell when bruiſed, approaching to that of Lavender Cotton, but not quite ſo rank. The flowers are produced in ſmall cluſters at the extremity of the branches, ſtanding erect; they are tubulous. The female florets which compoſe the rays, form a hollow, in the middle of which the hermaphrodite flowers are ſituated which form the diſk. The border is white, with a little reddiſh caſt on the inſide, and the diſk is of a purpliſh colour. The flowers appear in autumn, but are not ſucceeded by ſeeds in this country.

This plant is propagated by cuttings, which may be planted any time from May to the middle of Auguſt, for if they are planted later in the ſeaſon, there will not be time for them to get good root before the winter; theſe cuttings ſhould be planted in ſmall pots filled with light earth, and plunged into a very moderate hot-bed, where they ſhould be ſhaded from the ſun till they have taken root; theſe muſt be refreſhed with water two or three times a week, but they ſhould not have too much at each time, for much moiſture is very hurtful to theſe plants. When the cuttings have taken root, they ſhould be gradually inured to the open air, to prevent their ſhoots from being drawn up weak; afterward they ſhould be removed into the open air, and placed in a ſheltered ſituation, where they may remain till October, when they muſt be removed into an airy glaſs-caſe, that they may have as much ſun as poſſible, and enjoy the free air in mild weather, but ſecured from froſt and damp air, either of which will ſoon deſtroy them. During the winter they muſt be ſparingly watered, for the reaſon before given; but, in the ſummer, when the plants are placed in the open air, they will require to be frequently refreſhed with water in hot weather.

Theſe plants retain their leaves all the year, ſo they add to the variety of exotics in the winter ſeaſon.

ERUCA. Tourn. Inſt. R. H. 226. tab. 111. Braſſica. Lin. Gen. 734. Rocket; in French, *Roquette*.

The Characters are,

The empalement of the flower is compoſed of four oblong leaves, which ſtand erect, forming a tube. The flower hath four oblong petals, placed in form of a croſs, which are rounded at their ends, where they are broad, but narrow at their baſe, and are much longer than the empalement. It hath ſix ſtamina, four of which are a little longer than the empalement; the other two are ſhorter, terminated by acute ſegments. It hath an oblong taper germen, ſupporting a ſhort ſtyle, crowned by an obtuſe bifid ſtigma. The germen afterward becomes a taper-cornered pod with two cells, filled with roundiſh ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, which includes the plants whoſe flowers have four long and two ſhort ſtamina, and their ſeeds are contained in long pods. Dr. Linnæus has joined the common Rocket to his genus of Braſſica, and ſome of the other ſpecies he has diſtributed under his other genera; but as the common Rocket has been long eſtabliſhed as an officinal plant, I chuſe to continue this genus by its old title.

The Species are,

1. Eruca (*Sativa*) foliis pinnato-laciniatis, laciniis exterioribus majoribus. *Rocket with wing-ſhaped jagged leaves, whoſe outer ſegments are the largeſt.* Eruca ſativa major annua, flore albo ſtriato. J. B. 2. 859. *Greater Garden annual Rocket with a white ſtriped flower.*
2. Eruca (*Bellidis folia*) foliis lanceolatis, pinnato-dentatis, caule nudo ſimplici. *Rocket with ſpear-ſhaped leaves which are indented, and a naked ſingle ſtalk.* Eruca bellidis folio. Mor. Hiſt. 2. 231. *Rocket with a Daiſy leaf.*
3. Eruca (*Perennis*) foliis pinnatis glabris, caule ramoſo, floribus terminalibus. *Rocket with winged ſmooth leaves, and a branching ſtalk terminated by flowers.* Eruca tenuifolia perennis, flore luteo. J. B. 2. 861. *Narrow-leaved perennial Rocket with a yellow flower.*

4. Eruca (*Aſpera*) foliis dentato-pinnatifidis hirſutis, caule hiſpido, ſiliquis lævibus. *Rocket with indented, wing-pointed, hairy leaves, a rough ſtalk, and ſmooth pods.* Eruca ſylveſtris, major, lutea, caule aſpero. C. B. P. 98. *Greater wild Saffron-coloured Rocket with a rough ſtalk.*

5. Eruca (*Tenacetifolia*) foliis pinnatis, foliolis lanceolatis pinnatifidis. Prod. Leyd. 342. *Rocket with winged leaves, whoſe lobes are ſpear-ſhaped and wing-pointed.* Eruca Tenacetifolia. H. R. Par. *Rocket with a Tanſey leaf.*

6. Eruca (*Viminia*) foliis ſinuato-pinnatis, ſeſſilibus, caule ramoſo. *Rocket with wing-ſhaped ſinuated leaves ſitting cloſe to the ſtalks, which are branching.* Eruca Sicula burſæ paſtoris folio. C. B. P. 98. *Sicilian Rocket with a Shepherd's Purſe leaf.*

The firſt ſort is an annual plant, which was formerly much cultivated in the gardens as a ſallad herb, but at preſent is little known here, for it has been long rejected on account of its ſtrong ungrateful ſmell. It ſtands in the liſt of medicinal plants, but at preſent is ſeldom uſed, though it is reckoned a provocative and a good diuretic. If it is propagated for ſallads, the ſeeds ſhould be ſown in drills, in the ſame manner as is uſually practiſed for other ſmall ſallad herbs; for it muſt be eaten young, otherwiſe it will be too ſtrong for moſt palates. The winter and ſpring ſeaſons are the times when this herb is uſed; for when it is ſown in the ſummer, the plants ſoon run up to ſeed, and are then too rank. Where it is cultivated for the ſeed, which is ſometimes uſed in medicine, they ſhould be ſown in March, on an open ſpot of ground; and when the plants have put out four leaves, the ground ſhould be hoed to deſtroy the weeds, and the plants muſt be thinned, ſo as to leave them three or four inches aſunder; and in about five or ſix weeks after, the ground ſhould be a ſecond time hoed to deſtroy the weeds, which, if well performed, will prevent them from growing to injure the plants, till the ſeeds are ripe; when the plants ſhould be drawn up, and ſpread upon a cloth in the ſun for two or three days to dry, then the ſeeds may be beaten out of the pods, and put up for uſe.

The ſecond ſort grows naturally in the ſouth of France and Italy, where it is often eaten as a ſallad herb; this hath many ſpear-ſhaped leaves ariſing from the root, which are four or five inches long, and one inch broad in the middle, regularly indented on their edges, and ſpread on the ground; the ſtalks are ſingle, and riſe about a foot high; they are naked, ſeldom having more than one leaf, which is ſituated at the bottom; the flowers grow in looſe bunches on the top of the ſtalks, which are ſucceeded by pods two inches long, having two cells filled with ſmall round ſeeds. This is an annual plant, which may be propagated by ſeeds in the ſame manner as the former.

The third ſort grows naturally about Paris, and in many other parts of Europe; the leaves of this are narrow, and regularly divided like a winged leaf; the ſtalks branch out upward, and are terminated by looſe ſpikes of yellow flowers. This hath a perennial root, and an annual ſtalk.

The fourth ſort grows naturally upon old walls and buildings in many parts of England, where it continues flowering all the ſummer, but is rarely admitted into gardens. It is ſometimes uſed in medicine, for which reaſon I have here mentioned it.

The fifth ſort grows naturally about Turin, from whence I received the ſeeds. This hath fine divided leaves, ſomewhat like thoſe of Tanſey, but are of a hoary green colour; the ſtalks riſe a foot and a half high, which are fully garniſhed with leaves of the ſame form, but gradually diminiſh in their ſize upward; the flowers are produced in cluſters at the top of the ſtalks, they are ſmall, and of a pale yellow colour; theſe are ſucceeded by ſlender taper pods two inches long, which contain two rows of ſmall round ſeeds.

The ſixth ſort grows naturally in Italy and Spain; this is an annual plant, with many oblong leaves, which are ſmooth and regularly ſinuated on their ſides, in form of a winged leaf; they are five or ſix inches long, and one inch and a half broad, of a light green, having a hot biting taſte; the ſtalks riſe about a foot high, they are ſtrong, and divide into ſeveral branches; theſe are garniſhed with a ſingle leaf at each joint, ſhaped like thoſe below, but ſmaller. The flowers are produced in looſe cluſters at the end of the branches; theſe are white, and near as large as thoſe of the Garden Rocket, and are ſucceeded by taper pods three inches long, containing two rows of round ſeeds. Theſe plants are preſerved in ſome gardens for the ſake of variety, therefore they are here mentioned; and thoſe who are inclined to cultivate them, may do it by ſowing their ſeeds on a bed of light earth in an open ſituation; and when the plants come up, they will require no other culture but to thin them, and keep them clear from weeds. They flower in June and July, and their ſeeds ripen in Auguſt.

ERUCAGO. See Bunias.

ERVUM. Lin. Gen. Plant. 784. Tourn. Inſt. R. H. 398. tab. 221. *Bitter Vetch.*

The Characters are,

The empalement of the flower is divided into five equal parts, which end in acute points; the flower is of the butterfly kind, having a large, roundiſh, plain ſtandard, two obtuſe wings half the length of the ſtandard, and a ſhorter keel which is pointed. It hath ten ſtamina, nine joined, and one ſtanding ſeparate, terminated by ſingle ſummits. It hath an oblong germen, ſupporting a riſing ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes an oblong taper pod, jointed between each ſeed.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, which includes thoſe plants with a butterfly flower, with ten ſtamina ſeparated in two bodies. To this genus Dr. Linnæus has joined the Lens of Tournefort, and ſome ſpecies of Vicia. The difference which he makes between Vicia and Ervum is only in their ſtigmas, that of Vicia having an obtuſe ſtigma, bearded on the under ſide, and that of the Ervum is ſmooth.

The Species are,

1. Ervum (*Ervilia*) germinibus undato-plicatis foliis impari pinnatis. Hort. Upſal. 224. *Ervum whoſe germens are waved and folded, and unequal winged leaves.* Ervum verum. Camer. Hort. *The true Bitter Vetch.*

2. Ervum (*Lens*) pedunculis ſubbifloris ſeminibus compreſſis convexis. Lin. Sp. Plant. 738. *Ervum with foot-ſtalks having two flowers, and compreſſed ſeeds which are convex.* Lens vulgaris. C. B. P. 346. *Common Lentils.*

3. Ervum (*Monanthos*) pedunculis unifloris. Lin. Sp. Plant. 738. *Ervum with one flower on each foot-ſtalk.* Lens monanthos. H. L. 360. *One flowered Lentil.*

4. Ervum (*Tetraſpermum*) pedunculis ſubbifloris, ſeminibus globoſis quaternis. Flor. Suec. 606. *Ervum with two flowers on each foot-ſtalk, and four globular ſeeds in each pod.* Vicia ſegetum ſingularibus ſiliquis glabris. C. B. P. 345. *Corn Vetch with ſingle ſmooth pods.*

5. Ervum (*Hirſutum*) pedunculis multifloris, ſeminibus globoſis binis. Lin. Sp. Plant. 738. *Ervum having many flowers on a foot-ſtalk, and two globular ſeeds in each pod.* Vicia ſegetum, cum ſiliquis plurimis hirſutis. C. B. P. 345. *Corn-Vetch having many hairy pods.*

The firſt ſort grows naturally in Italy and Spain: it is an annual plant, which riſes with angular weak ſtalks a foot and a half high, garniſhed at each joint with one winged leaf, compoſed of fourteen or fifteen pair of lobes, very like thoſe of the Vetch, but narrower; the flowers come out from the ſide of the ſtalks, on foot-ſtalks an inch long, each ſuſtaining two pale-coloured flowers, which are ſucceeded by ſhort pods a little compreſſed, each having three or four round ſeeds; the pods ſwell at the place where each ſeed is lodged, ſo that it is called a jointed pod by many. The ſeeds of this plant ground to flour is ſometimes uſed in medicine; and the green herb is uſed for feeding of cattle in ſome countries, but it is not worth cultivating for that purpoſe in England.

The ſecond ſort is the common Lentil, which is cultivated in many parts of England, either as fodder for cattle, or for the ſeeds, which are frequently uſed for meagre ſoups. This is alſo an annual plant, and is one of the leaſt of the pulſe kind, which is cultivated: it riſes with weak ſtalks a foot and a half high, garniſhed with winged leaves at each joint, compoſed of ſeveral pair of narrow lobes, terminated by a tendril or claſper, which faſtens to any neighbouring plant, and is thereby ſupported; the flowers come out upon ſhort foot-ſtalks from the ſide of the branches; they are ſmall, of a pale purple colour, three or four ſtanding upon a foot-ſtalk; theſe are ſucceeded by ſhort flat pods, containing two or three ſeeds, which are flat, round, and a little convex in the middle. The flowers appear in May, and the ſeeds ripen in July. The ſeeds of this plant are commonly ſown in March, where the land is dry, but in moiſt ground the beſt time is in April. The uſual quantity of ſeed allowed to an acre of land, is from one buſhel and a half to two buſhels. If theſe are ſown in drills in the ſame manner as Peas, they will ſucceed better than when they are ſown in broad caſt: the drills ſhould be a foot and a half aſunder, to allow room for the Dutch hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the Lentils and ſtarve them. The ſeeds of theſe will ripen in July, when the plants ſhould be cut and dried, and afterward the ſeeds ſhould be threſhed out for uſe.

The ſeeds of Lentils are frequently the common food of the poorer ſort of people in ſome of the iſlands of the Archipelago, and other warm countries, when they can meet with no better fare; for theſe they loath, when they have better food, from whence came the proverb, *Dives factus jam diſit gaudere lente*; which is applied to thoſe who ſpurn at thoſe things in eaſy circumſtances, which they were glad of in a low condition.

There is another ſort of Lentil which has been cultivated of late years in England, by the title of French Lentil. This is the Lens major of Caſpar Bauhin, and is undoubtedly a different ſpecies from the common, being twice the ſize, both in plant and ſeed, and conſtantly produces the ſame from ſeeds, though they do not differ much in their characters, but this is much better worth cultivating than the other. This pulſe is frequently called Tills in many parts of England.

The third ſort is very like the common Lentil, but differs from it, in having but one flower on each foot-ſtalk, whereas the other has three or four, but in other reſpects is the ſame, ſo may be cultivated in the ſame manner.

The fourth and fifth ſorts are ſmall annual Vetches, which grow naturally among the Wheat and Rye in many parts of England, ſo are not admitted into gardens; they are only mentioned here as weeds, which may be eaſily rooted out of the fields, if they are cut up when they begin to flower, and not permitted to ripen their ſeeds; for as they have annual roots, ſo if they do not ſcatter their ſeeds, they may be ſoon deſtroyed.

ERVUM ORIENTALE. See Sophora.

ERYNGIUM. Lin. Gen. Plant. 287. Tourn. Inſt. R. H. 327. tab. 173. Sea Holly, or Eryngo.

The Characters are,

It hath many ſmall flowers ſitting upon one common conical receptacle, whoſe involucrum is compoſed of ſeveral plain leaves; the flowers have a five-leaved erect empalement, coloured on the upper ſide, ſitting upon the germen; theſe form a roundiſh general umbel, which is uniform. The flowers have five oblong petals, which are turned inward at top and bottom, and five erect hairy ſtamina, ſtanding above the flowers, terminated by oblong ſummits; under the empalement is ſituated a prickly germen, ſupporting two ſlender ſtyles, crowned by ſingle ſtigmas. The germen afterward becomes an oval fruit divided in two parts, each having one oblong taper ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and two ſtyles.

The Species are,

1. Eryngium (*Maritimum*) foliis radicalibus ſubrotundis plicatis ſpinoſis, capitulis pedunculatis. Hort. Cliff. 87. *Sea Holly whoſe lower leaves are folded, roundiſh, and prickly, and flower-heads having foot-ſtalks.* Eryngium maritimum. C. B. P. 386. *Sea Holly, or Eryngo.*
2. Eryngium (*Campeſtre*) foliis amplexicaulibus pinnato laciniatis. Hort. Cliff. 87. *Sea Holly whoſe leaves embrace the ſtalks, and are cut like winged leaves.* Eryngium vulgare. C. B. P. 386. *Common Eryngo.*
3. Eryngium (*Planum*) foliis radicalibus ovalibus planis crenatis, capitulis pedunculatis. Hort. Cliff. 87. *Sea Holly whoſe lower leaves are plain, oval, and crenated, with flower-heads having foot-ſtalks.* Eryngium latifolium planum. C. B. P. 386. *Broad-leaved plain Eryngo.*
4. Eryngium (*Amethyſtinum*) foliis trifidis baſi ſubpinnatis. Lin. Sp. Plant. 337. *Eryngo with trifid leaves, and thoſe at the baſe winged.* Eryngium montanum amethyſtinum. C. B. P. 386. *Purple Violet-coloured Mountain Eryngo.*
5. Eryngium (*Palleſcente*) foliis radicalibus rotundato-multifidis, capitulis pedunculatis. *Eryngo whoſe lower leaves are roundiſh and multifid, having foot-ſtalks to the heads of flowers.* Eryngium Alpinum amethyſtinum, capitulo majore palleſcente. Tourn. Inſt. 328. *Alpine Eryngo with a large pale-coloured head.*
6. Eryngium (*Orientale*) foliis radicalibus pinnatis, ſerrato-ſpinoſis, foliolis trifidis. *Eryngo whoſe lower leaves are winged, ſpiny indented, and the ſmaller ones trifid.* Eryngium Orientale, foliis trifidis. T. Cor. 23. *Oriental Eryngo with trifid leaves.*
7. Eryngium (*Aquaticum*) foliis gladiatis ſerrato-ſpinoſis, floralibus indiviſis caule ſimplici. Lin. Sp. Plant. 336. *Eryngo with ſword-ſhaped leaves which are ſpiny and indented, and the upper ones entire.* Eryngium foliis gladiolatis utrinque laxè ſerratis, denticulis ſubulatis. Lin. Hort. Cliff. 88. *American Sea Holly with leaves like the Aloe, lightly ſawed, commonly called Rattleſnake Weed in America.*
8. Eryngium (*Puſillum*) foliis radicalibus oblongis inciſis, caule dichotomo, capitulis ſeſſilibus. Hort. Cliff. 87. *Eryngo with oblong lower leaves which are cut, a ſtalk divided by pairs, and heads ſitting cloſe.* Eryngium planum minus. C. B. P. 386. *Leſſer plain Eryngo.*
9. Eryngium (*Alpinum*) foliis radicalibus cordatis oblongis, caulinis pinnatifidis, capitulo ſubcylindrico. Lin. Sp. Plant. 233. *Eryngo with oblong, heart-ſhaped, lower leaves, thoſe upon the ſtalks wing-pointed, and cylindrical heads.* Eryngium Alpinum cæruleum, capitulis diſpaci. C. B. P. 386. *Blue Alpine Eryngo with heads like the Teaſel.*
10. Eryngium (*Fœtidum*) foliis radicalibus ſubenſiformibus ſerratis floralibus multifidis caule dichotomo. Lin. Sp. Plant. 336. *Eryngo with ſword-ſhaped lower leaves having ſpiny ſaws, the upper leaves ending in many points.* Eryngium foliis anguſtis ſerratis fœtidum. Sloan. Cat. Jam. 127. *Stinking Eryngo having narrow ſawed leaves, commonly called Feverweed.*

The firſt of theſe ſpecies grows in great plenty on the ſandy and gravelly ſhores in divers parts of England, the roots of which are candied, and ſent to London for medicinal uſe, and is the true Eryngo. This hath creeping roots, which run deep into the ground; the leaves are roundiſh, ſtiff, and of a gray colour, ſet with ſharp ſpines on the edges. The ſtalks riſe a foot high, and divide upward into two or three ſmaller branches; they are ſmooth, and garniſhed at each joint with leaves of the ſame form as the lower, but ſmaller, which embrace the ſtalks with their baſe; at the end of the branches come out the flowers in roundiſh prickly heads; under each is ſituated a range of narrow, ſtiff, prickly leaves, ſpreading like the rays of a ſtar; the flowers are of a whitiſh blue colour. They appear in July, and the ſtalks decay in autumn.

This ſort will grow in a garden, if the roots are planted in a gravelly ſoil, and produce their flowers annually; but the roots will not grow near ſo large or fleſhy as thoſe which grow on the ſea-ſhore, where they are flowed with ſalt water. The beſt time to tranſplant the roots is in autumn, when their leaves decay; the young roots are much better to remove than the old, becauſe they are furniſhed with fibres, ſo will readily take root: when theſe are fixed in the ground, they ſhould remain unremoved; and if they are kept clean from weeds, it is all the culture they will require.

The ſecond ſort grows naturally in ſeveral parts of England, where it is a very troubleſome weed, for the roots run deep into the ground, ſo are not eaſily deſtroyed by the plough; and they ſpread and multiply greatly in the ground, to the prejudice of whatever is ſown or planted on the land, therefore it is not admitted into gardens.

The third ſort makes a very pretty appearance when it is in flower, eſpecially that with the blue ſtalks and flowers, for there is a variety of this with white flowers and ſtalks; but as this doth not ſpread at the root, but keeps within bounds, ſo a few of the plants ſhould be allowed a place in the pleaſure-garden. This is propagated by ſeeds, which, if ſown in the autumn, will more certainly ſucceed than when it is ſown in the ſpring, for the latter commonly remains in the ground a year before they vegetate; and if the ſeeds are ſown where the plants are to remain, they will flower ſtronger than thoſe which are tranſplanted; for as they have long downright roots, ſo theſe are commonly broken in taking out of the ground, which greatly weaken the plants. The culture they require is to thin them where they are too near, keep them clean from weeds, and dig the ground about them every ſpring before they ſhoot.

The ſtalks of this ſort will riſe from two to three feet high, the lower leaves are oval and plain; thoſe of the white ſort are of a lighter green than thoſe of the blue; the upper part of the ſtalks of the white are of that colour, thoſe of the blue are of the colour of amethyſt; the ſtalks divide upward, where they are garniſhed with leaves divided into many points ending with ſpines; the flowers are produced in oval heads at the top of the ſtalk, ſtanding upon ſeparate foot-ſtalks. The flowers come out in July, and the ſeeds ripen in September.

The fourth ſort grows naturally upon the mountains of Syria, and alſo upon the Apennines. The lower leaves of this ſort are divided like the fingers of a hand, into five or ſix ſegments, which are very much cut at their extremities into many parts, and have ſmall ſpines; the ſtalk riſes about two feet high, garniſhed with ſmaller and more divided leaves; the upper part of the ſtalk, and alſo the heads of flowers, are of the fineſt amethyſt colour, ſo that they make a very fine appearance. This ſort flowers in July, and when the autumn proves dry, their ſeeds will ripen in September, but in wet ſeaſons the ſeeds never ripen in England. This is propagated by ſeeds in the ſame manner as the former ſort.

The fifth ſort has been ſuppoſed by many, to be only a variety of the fourth; but I have propagated it by ſeeds more than thirty years, without finding the leaſt alteration, ſo that I make no doubt of its being a diſtinct ſpecies. The lower leaves of this are very much divided, and the extremity of the ſegments form an oval or circle; theſe are divided into many fine parts, which end in ſpines; they are of a whitiſh gray in the middle, and green on the borders. The ſtalks riſe about two feet high, garniſhed at the joints with ſmaller leaves which are finely cut; the flowers terminate the ſtalk, they are of a light blue colour, and grow in larger heads than either of the former ſorts. It flowers in June and July, and the ſeeds ripen in autumn. This grows naturally on the Alps; it is a perennial plant, and may be propagated by ſeeds in the ſame manner as the former.

The ſixth ſort was diſcovered by Dr. Tournefort in the Levant, from whence he ſent the ſeeds to the royal garden at Paris. This hath a perennial root, the lower leaves are regularly divided into ſeven or nine parts to the midrib, as the other winged leaves; theſe ſegments are ſawed on their edges, which end in ſharp thorns. The ſtalks riſe two feet high, ſending out ſide branches, garniſhed with ſtiff leaves, which are divided into narrower ſegments than the lower, and are terminated by three points. The flowers terminate the ſtalks, ſitting cloſe among the leaves, and are of a fine blue, as are alſo the leaves on the upper part of the ſtalks, ſo they make a pretty appearance. This flowers in July, but ſeldom ripens ſeeds in England. It is propagated in the ſame manner as the three former ſorts, and the plants require the ſame treatment.

The ſeventh ſort grows naturally in Virginia and Carolina, where it is titled Rattleſnake Weed, from its virtues of curing the bite of that venomous reptile. This hath a perennial root, from which ariſe ſeveral long leaves, which are ſawed on their edges, ending in ſpines; theſe leaves are diſpoſed round the root, after the ſame form of the Aloe or Yucca; they are of a gray colour, a foot long or more, and one inch and a half broad, ſtiff, and end in ſpines. The ſtalk is ſtrong, grows two feet high, dividing upward into ſeveral foot-ſtalks, each being terminated by an oval head of flowers, ſhaped like thoſe of the former ſorts; they are white, with a little caſt of pale blue. This ſort flowers in July, but unleſs the ſeaſon is very warm, the ſeeds will not ripen in England.

This ſort is propagated by ſeeds, which, if ſown in pots and plunged into a moderate hot-bed, the plants will come up much ſooner than thoſe which are ſown in the full ground, whereby they will be much ſtronger before the winter. When the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, filled with light earth; and if they are plunged into a moderate hot-bed, it will forward their taking root; then they muſt be gradually inured to bear the open air, into which they may be removed toward the latter end of May, and placed among other hardy exotic plants. When the plants have filled theſe pots with their roots, ſome of them may be ſhaken out, and planted in a warm border; the others may be put into larger pots, and in the autumn placed under a common frame, where they may be expoſed to the free air in mild weather, but ſheltered from ſevere froſt: the following ſpring theſe may be turned out of the pots, and planted in a warm ſituation, where they will endure the cold of our ordinary winters very well; and if in ſevere froſt they are covered with Straw, Peas-haulm, or any ſuch light covering, it will ſecure them from injury.

The eighth ſort grows naturally in Spain and Italy. This puts out oblong plain leaves from the root, which are cut on their edges; the ſtalks riſe about a foot high, and branch out into many forked diviſions, which are regular, and at each of theſe diviſions is ſituated a ſmall head of flowers, ſitting very cloſe between the branches. Theſe have no great beauty, ſo the plants are ſeldom cultivated in gardens, except for the ſake of variety.

The ninth ſort grows naturally on the mountains of Helvetia and Italy. The root is perennial, the lower leaves are oblong, heart-ſhaped, and plain; the ſtalks riſe from two to three feet high, branching out on their ſides upward; theſe are garniſhed with ſtiff leaves, which are deeply divided, ending in many points with ſharp ſpines; the flowers terminate the ſtalks, they are collected into conical heads, and are of a light blue colour, as are alſo the upper part of the ſtalks. This flowers in July, and the ſeeds are ripe in September; it is propagated by ſeeds in the ſame manner as the other ſorts.

The tenth ſort grows naturally in the Weſt-Indies, where it is much uſed in medicine, being accounted of great ſervice in the cure of fevers, from whence it hath the appellation of Feverweed in thoſe countries. The roots of this plant are compoſed of many ſmall fibres, which ſpread near the ſurface; the lower leaves are ſix or ſeven inches long; they are narrow at their baſe, and enlarge upward to an inch in breadth near the top, where they are rounded off on one ſide like a ſcymitar; they are finely ſawed on their edges, and are of a light green colour; the ſtalk riſes about a foot high, and ſpreads out into many branches, garniſhed with ſmall leaves, which end in many points; the flowers are produced in ſmall heads which ſit cloſe to the ſtalks, coming out at every diviſion of the ſtalks, and at the end of the branches; theſe are of a dull white colour, ſo make little appearance. They appear in June and July, and the ſeeds ripen in autumn. As this plant is a native of hot countries, ſo it will not thrive in England, but in a warm ſtove. It is propagated by ſeeds, which muſt be ſown on a hot-bed; and when the plants are fit to remove, they ſhould be each planted into a ſmall pot, and plunged into the bark-bed, and afterward treated like other tender plants from the ſame country; the ſecond year they will produce flowers and ſeeds, ſoon after which they commonly decay.

ERYSIMUM. Lin. Gen. Plant. 729. Tourn. Inſt. R. H. 228. tab. 111. ['Ερύσιμον, of ἐρύω, *Gr.* to draw out, becauſe this plant, by means of its hot quality, has the quality of drawing any thing out of the body in which it lies hid.] Hedge-Muſtard; in French, *Velar*, or *Tortelle*.

The CHARACTERS are,

The empalement of the flower is compoſed of four oblong, oval, coloured leaves; the flower hath four petals, placed in form of a croſs; theſe are oblong, plain, and obtuſe; it hath two nectarious glands, ſituated between the ſtamina. It hath ſix ſtamina, four of which are the length of the empalement, the other two are a little ſhorter, terminated by ſingle ſummits. It hath a very narrow four-cornered germen as long as the ſtamina, with a ſhort ſtyle, crowned by a ſmall permanent ſtigma; the germen afterward becomes a long, narrow, four-cornered pod with two cells, filled with ſmall round ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifteenth claſs, which includes thoſe plants whoſe flowers have four long and two ſhort ſtamina, and the ſeeds are included in long pods.

The SPECIES are,

1. ERYSIMUM (*Officinale*) ſiliquis ſpicæ adpreſſis foliis runcinatis. Hort. Cliff. 337. *Hedge Muſtard whoſe pods are preſſed cloſe to the ſpikes.* Eryſimum vulgare. C. B. P. 100. *Common Hedge Muſtard.*
2. ERYSIMUM (*Barbarea*) foliis lyratis extimo ſubrotundo. Flor. Suec. 557. *Hedge Muſtard with harp-ſhaped leaves, the outer ſegment being roundiſh.* Siſymbrium erucæ folio glabro flore. Tourn. Inſt. 226. *Winter Creſs with a Rocket leaf and yellow flower.*
3. ERYSIMUM (*Vernum*) foliis radicalibus lyratis, caulinis pinnato-ſinuatis, floribus laxè ſpicatis. *Hedge Muſtard with lower leaves ſhaped like a harp, thoſe on the ſtalks ſinuated and winged, and flowers growing in looſe ſpikes.* Siſymbrium erucæ folio glabro minus & præcocius. Tourn. Inſt. 226. *Smaller early Winter-Creſs with a ſmooth Rocket leaf.*
4. ERYSIMUM (*Orientale*) foliis radicalibus ovatis integerrimis, petiolis decurrentibus, caulinis oblongis dentatis ſeſſilibus. *Hedge Muſtard with lower leaves oval and entire, a winged foot-ſtalk, and the leaves upon the ſtalks oblong, indented, and ſitting cloſe.* Siſymbrium Orientale barbareæ facie, plantaginis folio. Tourn. Cor. 16. *Oriental Siſymbrium with the appearance of Water-Creſs and a Plantain Leaf.*
5. ERYSIMUM (*Minus*) foliis inferioribus pinnato-ſinuatis, ſuperioribus oblongis dentatis, floribus ſolitariis alaribus. *Hedge Muſtard whoſe lower leaves are winged and ſinuated, the upper oblong and indented, and ſingle flowers proceeding from the ſides of the ſtalks.* Siſymbrium minus erucæ folio glabro nigro, craſſo lucido. Boerh. Ind. alt. 2. 16. *Smaller Winter Creſs, with a ſmooth, dark, thick, ſhining Rocket leaf.*
6. ERYSIMUM (*Alliaria*) foliis cordatis. Hort. Cliff. 338. *Hedge Muſtard with heart-ſhaped leaves.* Heſperis allium redolens. Mor. Hiſt. 2. 252. *Dames Violet ſmelling like Garlick, commonly called Alliaria, Sauce alone, or Jack by the Hedge.*
7. ERYSIMUM (*Cheiranthoides*) foliis lanceolatis integerrimis. Flor. Lapp. 263. *Hedge Muſtard with entire ſpear-ſhaped leaves.* Leucoium heſperidis folio. Tourn. Inſt. 221. *Gilliflower with a Dames Violet leaf.*

The firſt ſort is uſed in medicine; this grows naturally on the ſide of foot-paths, and upon old walls in moſt parts of England, ſo is rarely cultivated in gardens, where, if it is once admitted, will ſoon become a troubleſome weed.

The ſecond and third ſorts alſo grow naturally on the banks in moſt parts of England; theſe were formerly eaten in winter ſallads, before the Engliſh gardens were furniſhed with better plants; ſince when they have been rejected, for they have a rank ſmell, and are diſagreeable to the palate.

The fourth and fifth ſorts are not natives of this country, but ſince they have been introduced into ſome Engliſh gardens, they have propagated themſelves by their ſcattered ſeeds in ſo plentiful a manner, as to become troubleſome weeds. Theſe have a reſemblance of the common Winter Creſs, but the lower leaves of the fourth ſort are entire, and of an oblong form; the upper leaves are oblong and indented, in which this differs.

The fifth ſort hath thicker leaves, which are of a dark lucid green colour, and the flowers come out ſingle from the wings of the ſtalk the whole length. Theſe differences are laſting, and do not alter.

The ſixth ſort grows naturally on the ſides of banks in many parts of England, ſo is not ſuffered to have a place in gardens. This was formerly eaten as a ſallad herb by the poorer ſort of people, who gave it the title of Sauce alone. This hath a rank ſmell and taſte of Garlick, and is very biting and hot on the palate; it is frequently preſcribed in medicine.

The ſeventh ſort is ſometimes found growing naturally upon old walls in ſome parts of England, particularly at Cambridge and Ely, at both which places I have obſerved it. This hath pretty long, hairy, ſoft leaves at the root; the ſtalks riſe near a foot high, their upper part being garniſhed with ſmall greeniſh white flowers in looſe ſpikes; theſe are ſucceeded by long compreſſed pods which hang downward. It flowers in May, and the ſeeds ripen in July and Auguſt; but the roots will abide ſeveral years, if they have a dry lean ſoil, or grow upon a wall, for in rich land they ſoon decay.

The other ſorts are ſometimes kept in botanic gardens for the ſake of variety; they are biennial plants, which periſh after they have perfected their ſeeds. Theſe may be propagated by ſowing their ſeeds in the autumn, in the places where they are to remain, and require no other culture but to thin them, and keep them clear from weeds.

ERYTHRINA. Lin. Gen. Plant. 762. Corallodendron. Tourn. Inſt. R. H. 661. tab. 446. Coral-tree.

The CHARACTERS are,

The flower hath a tubulous empalement of one leaf, which is entire and indented at the brim. The flower is of the butterfly kind, compoſed of five petals; the ſtandard is ſpear-ſhaped, and deflexed on the ſtyles; it is very long, and riſes upward; the two wings are ſcarce longer than the empalement, and are oval; the keel is compoſed of two petals which are no longer than the wings, and are indented at the top; it hath ten ſtamina which are joined below, and are a little curved, about half as long as the ſtandard, and are unequal in their length, terminated by arrow-pointed ſummits; it hath an awl-ſhaped germen with a foot-ſtalk, narrowed at the ſtyle, which is the length of the ſtamina, terminated by a ſingle ſtigma. The germen afterward becomes a long ſwelling pod ending in an acute point, having one cell, filled with kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, which includes the plants with a butterfly flower, having ten ſtamina joined in two bodies.

The SPECIES are,

1. ERYTHRINA (*Herbacea*) foliis ternatis, caule ſimpliciſſimo inermi. Hort. Cliff. 354. *Erythrina with trifoliate leaves, and a ſingle ſmooth ſtalk.* Corallodendron humile, ſpicâ florum longiſſimâ, radice craſſiſſimâ. Cateſb. Carol. 49. tab. 49. *Low Coral-tree with a very*

long ſpike of flowers and thick root, commonly called the Carolina Coral-tree.

2. **Erythrina** (*Corallodendron*) inermis, foliis ternatis, caule arboreo. *Smooth Erythrina with trifoliate leaves, and a tree-like ſtalk.* Coral arbor Americana. Hort. Amſt. 1. p. 211. *Smooth American Coral-tree.*
3. **Erythrina** (*Spinoſa*) foliis ternatis, caule arboreo aculeato. Hort. Cliff. 354. *Erythrina with trifoliate leaves, and a tree-like prickly ſtalk.* Corallodendron triphyllum Americanum, ſpinoſum, flore ruberrimo. Tourn. Inſt. R. H. 661. *Prickly three-leaved American Coral-tree, with a very red flower.*
4. **Erythrina** (*Picta*) foliis ternatis aculeatis caule arboreo aculeato. Lin. Sp. 993. *Erythrina with trifoliate prickly leaves, and a prickly tree-like ſtalk.* Corallodendron triphyllon Americanum, minus ſpinis & ſeminibus nigricantibus. Tourn. Inſt. R. H. 661. *Smaller three-leaved American Coral-tree, with blacker ſpines and ſeeds.*
5. **Erythrina** (*Americana*) foliis ternatis acutis, caule arboreo aculeato, floribus ſpicatis longiſſimis. *Erythrina with trifoliate acute-pointed leaves, a prickly tree-like ſtalk, and very long ſpikes of flowers.* Corallodendron triphyllon Americanum, foliis mucronatis, ſeminibus coccineis. Houſt. MSS. *Three-leaved American Coral-tree, with acute-pointed leaves and ſcarlet ſeeds.*
6. **Erythrina** (*Inermis*) foliis ternatis acutis, caule fruticoſo inermi, corollis longioribus clauſis. *Erythrina with acute trifoliate leaves, a ſhrubby unarmed ſtalk, and longer flowers which are cloſed.* Coral arbor non ſpinoſa, flore longiore & magis clauſo. Sloan. Cat. Jam. 142. *Coral-tree without ſpines, having a longer cloſer flower.*

The firſt ſort grows naturally in South Carolina, from whence Mr. Cateſby ſent the ſeeds in the year 1724, and many of the plants were then raiſed in ſeveral curious gardens. This hath a very large woody root, which ſeldom riſes more than a foot and a half high, from which come out freſh ſhoots every ſpring; theſe grow about two feet high, their lower part being garniſhed with trifoliate leaves, of a deep green colour, which are ſhaped like the point of an arrow; the upper part of the ſtalks are terminated by a long ſpike of ſcarlet flowers, compoſed of five petals, the upper petal being much longer than the other, ſo that at a ſmall diſtance the flowers appear to have but one petal. After the flowers are paſt, the germen turns to a taper pod five or ſix inches long, ſwelling in every part where the ſeeds are lodged, opening in one cell, containing five or ſix kidney-ſhaped ſcarlet ſeeds. Theſe plants flower in England, but they never produce ſeeds here.

The ſecond ſort hath a thick woody ſtem, which riſes about ten or twelve feet high in this country, but in its native country grows to twice that height, ſending out many ſtrong irregular branches, which are covered with a brown bark, garniſhed with trifoliate leaves ſtanding upon long foot-ſtalks, the middle lobe which terminates the leaf, being much larger than the other two; they are all heart-ſhaped, ſmooth, and of a deep green colour; the flowers come out at the end of the branches, in ſhort, thick, cloſe ſpikes; they are of a deep ſcarlet colour, and make a fine appearance. Theſe commonly are in beauty in May and June in this country, but are not ſucceeded by pods here; but in America, where the trees grow naturally, they have thick, ſwelling, crooked pods, which contain large kidney-ſhaped ſeeds, of a reddiſh purple colour. The leaves of this tree decay in the ſpring and fall off, ſo that in ſummer they appear to have no life; but in the autumn it puts out new leaves, which continue green all the winter. The flowers do not appear till the leaves drop, ſo that the branches are often naked at the time when the flowers are out.

The third ſort chiefly differs from the ſecond, in having its trunk, branches, and the foot-ſtalks of the leaves, armed with ſhort crooked ſpines, the leaves and flowers being very like thoſe of the ſecond ſort.

The fourth ſort hath ſhrubby ſtalks, which divide into branches, and ſeldom riſe above eight or nine feet high; theſe are armed in every part with ſtrong, crooked, black ſpines; the leaves are ſmaller than thoſe of the two laſt ſorts, and have a nearer reſemblance of the firſt; the foot-ſtalks of the leaves are armed with the ſame ſort of ſpines, and the midrib of the leaves have alſo ſome which are ſmaller and not ſo black; the flowers are of a paler ſcarlet, and grow in looſer ſpikes. The ſeeds are as large as thoſe of the ſecond ſort, but are of a dark purple colour.

This tree is generally planted in the Eaſt-Indies for a ſupport to the Pepper plants, which twine round the ſtem and branches, whereby they are prevented trailing on the ground; and as the branches of this tree will put out roots and grow, ſo they are preferable to any dead props, which in thoſe hot countries, where there is much rain, would ſoon rot.

The ſeeds of the fifth ſort were ſent me from La Vera Cruz, where the plants grow naturally; and ſince I have received ſeeds of the ſame ſort from the Cape of Good Hope, ſo that it is a native of both countries. The ſeeds of this are not half ſo large as thoſe of the ſecond or third ſorts, and are of a bright ſcarlet colour; the leaves are alſo much ſmaller, and have long acute points; the branches are very cloſely armed with crooked greeniſh ſpines, as are alſo the ribs and foot-ſtalks of the leaves. The flowers grow in very long cloſe ſpikes, and are of a beautiful ſcarlet colour.

I have alſo raiſed a variety of this with paler flowers and ſeeds, and the plants were leſs thorny; but as I was doubtful of its being a diſtinct ſpecies, ſo I only mention it here.

The ſixth ſort grows in Jamaica, and ſome of the other iſlands in America, from whence I have received the ſeeds. The pods of this ſort are longer, and not more than half ſo thick as thoſe of the ſecond ſort; the ſeeds are of a bright ſcarlet colour, they are longer and ſlenderer than thoſe of the other ſorts; the leaves are ſmall and acute-pointed, and the ſtalks are ſmooth and without ſpines: this doth not grow very large, but ſhoots out into branches at a little diſtance from the ground, which grow erect, ſo form a buſhy ſhrub. The flowers come out at the end of the branches in ſhort ſpikes; the ſtandard of the flower is long, and the ſides turn down over the wings, which are alſo longer than thoſe of the other ſpecies, and the whole flower is more cloſed.

I have alſo received ſpecimens of a variety of the third ſort from the iſland of Barbuda, with very ſhort flowers and pods; they came by the title of Bean-tree, which is the common appellation given to theſe trees in America; but the flowers were ſeparated from the ſtalks, ſo that I can give no account in what manner they grow, whether in long or ſhort ſpikes; but the ſtamina of theſe are much longer than the petals, in which it differs from all the other; the pods are very ſhort and crooked, but are rather thicker than thoſe of the third ſort; the leaves have the ſame appearance, and are armed with ſpines, as are alſo the ſtalks and branches, but the plants have not as yet produced any flowers here.

A few years ago I received a few very ſmall ſeeds of a Coral-tree from the Cape of Good Hope, which were of a bright ſcarlet colour; the plants have no ſpines on them, the leaves are much larger than the other ſorts, their ſtems are ſtrong, and have the appearance of growing to large trees; but as they are young, ſo there is no determining how they may differ from the other ſpecies.

There are two other ſorts of Coral-tree mentioned by Sir Hans Sloane, in his Hiſtory of Jamaica: one of which is by its characters a Sophora, under which genus we ſhall place it; and the other will be put under Robinia, to which genus it properly belongs.

Theſe plants when they produce their flowers, are ſome of the greateſt ornaments to the ſtoves we yet know; for their flowers are produced in large ſpikes, and are of a beautiful ſcarlet, ſo they make a fine appearance; but it is ſeldom they flower here, or in any of the northern parts of Europe; yet in the countries where they naturally grow, they produce flowers in great plenty every year; ſo that it is very common there to ſee moſt of their branches terminated by large ſpikes of flowers, when they have no leaves upon them; and the firſt ſort, which grows in Carolina, is equally productive of flowers there, tho' here they do not flower oftener than once in two or three years, and the other ſorts not ſo frequent. I have tried by various methods to get them to flower; ſome I have treated hardily, by expoſing them to the open air during the ſummer ſeaſon, and in the winter kept them in a very moderate temperature of warmth; others I have kept plunged all the year in the tan-bed of the ſtove, and ſome have remained in a dry ſtove all the year, where in warm weather they had a large ſhare of air admitted to them, and in winter the air was kept to the temperate point. In this laſt place the plants have ſucceeded beſt, yet with this treatment they ſeldom flower; and this is the general complaint of every one who is poſſeſſed of theſe plants, not only in England, but alſo in Holland and France.

The firſt ſort may be kept through the winter in a warm green-houſe, but the plants ſo kept rarely flower; and the two ſorts which I have received from the Cape of Good Hope, have lived through the winter in a warm glaſs-caſe, without fire; but theſe have not made ſo good progreſs, as thoſe plants which were kept in a temperate warmth; ſo that in this country, it is much the beſt method of treating theſe plants, eſpecially while they are young.

Theſe plants are beſt propagated by ſeeds, when they can be procured from the countries where they naturally grow, for they do not produce any here, tho' they are annually brought to England in plenty. The ſeeds ſhould be ſown in ſmall pots, and plunged into a moderate hot-bed; where, if the ſeeds are good, the plants will come up in a month or five weeks; when they are two inches high, they ſhould be carefully ſhaken out of the pots, and each planted in a ſeparate ſmall pot, filled with light earth, and plunged into a moderate hot-bed of tanners bark, where they muſt be ſhaded from the ſun till they have taken new root; then they ſhould have a large ſhare of air admitted to them at all times when the weather is warm, to prevent their being drawn up weak; and as the plants increaſe in ſtrength, ſo they muſt have a larger ſhare of air. They muſt be frequently refreſhed with water, but not given to them in great plenty, for too much moiſture will rot the fibres of their roots. In the autumn the plants ſhould be removed into the ſtove; and for the two or three firſt winters, while the plants are young, they will require more warmth than when they have acquired more ſtrength. During the time the leaves continue in vigour, the plants will require to have water two or three times a week; but when they are deſtitute of leaves, it muſt be ſparingly given, for moiſture then is very hurtful to them. As the plants grow in ſtrength, ſo they muſt be more hardily treated; and by managing them differently, there will be a greater chance of getting them to flower.

The third ſort is frequently planted in the gardens near Liſbon, where they annually flower and ripen their ſeeds, which have been brought me by perſons who gathered the pods from the trees.

Theſe plants may alſo be propagated by cuttings, which, if planted in pots during the ſummer months, and plunged into a hot-bed, will take root, but the ſeedling plants are beſt.

ERYTHRONIUM. Lin. Gen. Plant. 375. Dens canis. Tourn. Inſt. R. H. 378. tab. 202. Dog's Tooth, or Dog's Tooth Violet.

The CHARACTERS are,

The flower has no empalement; it is bell-ſhaped, and compoſed of ſix oblong petals, which ſpread open to their baſe. It hath ſix ſtamina joined to the ſtyle, terminated by oblong, erect, quadrangular ſummits. In the center is ſituated an oblong, obtuſe, three-cornered germen, ſupporting a ſingle ſtyle which is longer than the ſtamina, crowned by a triple, obtuſe, ſpreading ſtigma. The germen afterward becomes an oblong obtuſe capſule with three cells, filled with flat ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, in which he places thoſe plants whoſe flowers have ſix ſtamina and one ſtyle.

The SPECIES are,

1. ERYTHRONIUM (*Dens Canis*) foliis ovatis. *Erythronium with oval leaves.* Dens canis latiore rotundioreque folio, flore ex purpurâ rubente. C. B. P. 87. *Dog's Tooth Violet with a broader and rounder leaf, and a purple red flower.*
2. ERYTHRONIUM (*Longifolium*) foliis lanceolatis. *Erythronium with ſpear-ſhaped leaves.* Dens canis anguſtiore longioreque folio, flore ex albo purpuraſcente. C. B. P. 87. *Dog's Tooth Violet, with a longer and narrower leaf, and a purpliſh white flower.*

Theſe are the only diſtinct ſpecies which I have ſeen, but there are ſome varities of them, which are preſerved in curious gardens. Of the firſt ſort there is a white flower, which is pretty common in the gardens; another with a pale purple, and a third with yellow flowers, which are rare in England: and of the ſecond ſort there is one with a white, and another with a ſoft red flower, both which are now very rare in the gardens.

The firſt ſort ſends out two oval leaves, which are joined at their baſe: they are three inches long and one and a half broad in the middle, gradually leſſening toward the end; theſe at firſt embrace each other incloſing the flower, but afterward they ſpread flat upon the ground; they are ſpotted with purple and white ſpots all over their ſurface; between theſe riſes a ſingle naked ſtalk about four inches high, which is ſmooth, of a purple colour; this ſuſtains one flower, compoſed of ſix ſpear-ſhaped petals, which in this are purple, but in ſome they are white; the flower hangs downward, and the petals reflex and ſpread open to their baſe. In the center is ſituated the oblong three-cornered germen, ſupporting a ſingle ſtyle which is longer than the ſtamina, crowned by a triple ſtigma; the purple ſtamina ſtand cloſe about the ſtyle, and the ſtigma ſtands farther out. This plant flowers early in April, but ſeldom produces ſeeds in England. The root of this plant is white, oblong, and fleſhy, and ſhaped like a tooth; from whence it had the title of Dog's Tooth.

The ſecond ſort differs from the firſt in the ſhape of its leaves, which are longer and narrower, and the flowers are a little larger but not ſo well coloured. They grow naturally in Hungary, and in ſome parts of Italy. They are propagated by offſets from their roots, which they do not ſend out very plentifully, ſo they are not ſo commonly ſeen in the gardens, as moſt other flowers of the ſame ſeaſon: they love a ſhady ſituation and a gentle loamy ſoil, but ſhould not be too often removed. They may be tranſplanted any time after the beginning of June, when their leaves will be quite decayed, till the middle of September; but the roots ſhould not be kept very long out of the ground, for if they ſhrink, it will often cauſe them to rot. The roots of theſe flowers ſhould not be planted ſcattering in the borders of the flower-garden, but in patches near each other, where they will make a good appearance.

ESCHYNOMENE. See ÆSCHYNOMENA.

ESCHYNOMENOUS, ÆSCHYNOMENOUS PLANTS [Αἰσχυνόμενοι, of αἰσχύνομαι, *Gr.* to be aſhamed,] the ſenſitive plants; which, when one touches them, will ſhrink in, or let their leaves fall down.

ESCULENT PLANTS [of eſculentus, *Lat.* eatable,] ſuch plants, or the roots of them, as may be eaten; as Beets, Carrots, Leeks, Onions, Parſneps, Potatoes, Radiſhes, Horſe-radiſh, Scorzonera, &c.

ESPALIERS, are either rows of trees planted about a whole garden or plantation, or in hedges, ſo as to incloſe quarters or ſeparate parts of a garden, which are trained up flat in a cloſe hedge, for the defence of tender plants againſt the violence and injury of wind and weather.

The moſt commonly received notion of Epaliers are hedges of fruit-trees, which are trained up regularly to a lattice of wood work, formed either of Aſh-poles, or ſquare long timbers cut out of Fir, &c. and it is of this ſort of Eſpalier that I ſhall treat in this place.

Eſpaliers of fruit-trees are commonly planted to ſurround the quarters of a kitchen-garden, for which purpoſe they are of admirable uſe and beauty; for by laying out the walks of this garden regularly, which are bounded on each ſide by theſe hedges, when they are handſomely managed, they have a wonderful effect in ſheltering the kitchen-plants in the quarters, and alſo ſcreening them from the ſight of perſons in the walks; ſo that a kitchen-garden well laid out in this manner, and properly managed, will be equal to the fineſt regular parterre for beauty.

The trees chiefly planted for Eſpaliers are Apples, Pears, and ſome Plums; but the two former are moſtly uſed: ſome plant Eſpaliers of Apples grafted upon Paradiſe-ſtocks; but theſe being of humble growth, and a ſhort duration, are not ſo proper for this purpoſe, unleſs for very ſmall gardens; therefore I ſhould rather adviſe the having them upon Crab-ſtocks, or (if in ſmaller gardens, where the trees cannot be allowed to grow ſo high) upon what the gardeners call the Dutch-ſtock; which will cauſe them to bear ſooner, and prevent their growing too luxuriantly, and theſe will continue many years in vigour.

In chuſing the trees for an Eſpalier, endeavour as near as poſſible, to plant the ſeveral ſorts which are nearly of the ſame growth in one line, that the Eſpalier may be the more regular, and of an equal height, which greatly adds to their beauty; for if you plant trees which ſhoot very unequally in the ſame line, it will be impoſſible to make the Eſpalier regular: beſides, the diſtance of the trees muſt be in proportion to their growth; for ſome trees, viz. thoſe of a larger growth, ſhould be planted thirty or thirty-five feet aſunder; whereas thoſe of ſmaller growth, need not be above twenty-five feet diſtance from each other.

The width of the walks and borders between theſe Eſpaliers ſhould (in a large garden) be fourteen or ſixteen feet at leaſt; and if the trees are deſigned to be carried up pretty high, the diſtance ſhould be greater, that each ſide may receive the advantage of the ſun and air, which is abſolutely neceſſary, if you would have the fruit well taſted. And if your ground is ſo ſituated, that you are at full liberty which way to make the Eſpaliers, I would adviſe the placing the lines from the eaſt a little inclining to the ſouth, and toward the weſt a little inclining to the north, that the ſun may ſhine between the rows in the morning and evening when it is low; for in the middle of the day, when the ſun is advanced far above the horizon, it will ſhine over the tops of the Eſpaliers, and reach the ſurface of the earth about their roots, which is a matter of more conſequence than many people are aware of.

The ſorts of Apples proper for Eſpaliers, are the Golden Pippin, Nonpareil, Rennette Griſe, Aromatick Pippin, Holland Pippin, French Pippin, Wheeler's Ruſſet, Pile's Ruſſet, with ſome others. The ſeaſon for planting, and the method of pruning and training theſe trees, you will ſee under the articles of APPLES and PRUNING.

The ſorts of Pears proper for an Eſpalier, are chiefly the ſummer and autumn fruits, for ſome of the winter Pears ſeldom ſucceed well in an Eſpalier. Theſe trees, if deſigned for a ſtrong moiſt ſoil, ſhould be upon Quince-ſtocks; but if for a dry ſoil upon free-ſtocks. Their diſtance of planting muſt alſo be regulated by the growth of the trees, which are more unequal in Pears than Apples, and ſhould therefore be more carefully examined before they are planted. As for thoſe Pears upon free-ſtocks, the diſtance ſhould never be leſs than thirty feet for moderate growing trees; but for vigorous ſhooters, the ſpace of forty feet is little enough; eſpecially if the ſoil be ſtrong, in which caſe they ſhould be planted at a greater diſtance.

The particular ſorts of Pears I would recommend for an Eſpalier, are the Jargonelle, Blanquette, Poire ſans Peau, Summer Boncretien, Hamden's Bergamot, Autumn Bergamot, L'ambrette, Gros Rouſſelet, Chaumontelle, Beurre du Roy, Le Marquis, Creſſane, with ſome others of leſs note; always remembering, that thoſe Pears which are of the melting kind, will do better in Eſpalier than the breaking Pears, which ſeldom ripen well on an Eſpalier; as alſo that many ſorts of Pears will ripen well on an Eſpalier in a warm ſoil and ſituation, which require a wall in other places; you ſhould alſo be careful of the ſtocks theſe are grafted on; for if the breaking Pears are grafted upon Quince-ſtocks, the fruit will be ſtony, but the melting Pears will be improved by them. As to the method of planting, ſee the article PEAR; and for pruning and managing, ſee PRUNING.

I ſhall now give directions for making the Eſpalier, to which the trees are to be trained; but this ſhould not be done until the third year after the trees are planted; for while they are young, it will be ſufficient to drive a few ſhort ſtakes into the ground on each ſide of the trees, in a ſtrait line, to which the branches ſhould be faſtened in an horizontal poſition, as they are produced, in order to train them properly for the Eſpalier; which ſtakes may be placed nearer, or at a farther diſtance, according as the ſhoots produced may require; and theſe will be ſufficient for the three firſt years; for ſhould you frame the Eſpalier the firſt year the trees are planted, many of the ſtakes would rot before the Eſpalier is covered. The cheapeſt method to make theſe Eſpaliers is with Aſh-poles, of which you ſhould have two ſorts; one of the largeſt ſize, which contains thirteen poles in a bundle, and the other ſize thoſe of half a hundred. The firſt or largeſt ſize poles, ſhould be cut about ſeven feet and a half long; theſe are intended for upright ſtakes, and muſt be ſharpened at the largeſt end, that they may, with more eaſe, be driven into the ground; and if their bottoms are burred, or rubbed over with that compoſition mentioned in the article of COVERINGS, they may be preſerved a long time ſound; theſe ſhould be placed at a foot diſtance from each other in a direct line, and of an equal height, about ſix feet above ground; then you ſhould nail a row of ſtrait ſlender poles along upon the tops of the upright ſtakes, which will keep them exactly even, and continue to croſs the ſtakes with the ſmaller poles, and alſo with the tops which were cut off from the larger ſtakes, at about nine inches diſtance, row from row, from the top to the bottom of the ſtakes. Theſe rows of poles ſhould be faſtened with wire to the ſtakes, which if made of Fir, and painted over, will laſt a long time; and the largeſt end of the poles ſhould be cut flat, and nailed to the upright ſtakes, which will ſecure the Eſpalier almoſt as long as the poles will endure; whereas, if your faſtening is not ſtrong, the poles will be continually diſplaced with every ſtrong wind.

When your Eſpalier is thus framed, you muſt faſten the branches of the trees thereto either with ſmall Oſier-twigs, rope-yarn, or ſome ſuch binding, obſerving to train them in a horizontal poſition, and at equal diſtances; being careful not to croſs any of the branches, nor to lay them in too thick. The diſtance which ſhould be allowed for the branches of Pears and Apples, muſt be proportioned according to the ſize of their fruit; ſuch of them whoſe fruit is large, as the Summer Boncretien, Monſieur John, and Beurre du Roy Pears, and the Rennet Griſe, Holland Pippin, French Pippin, and other large Apples, ſhould have their branches ſix or eight inches diſtance at leaſt; and to thoſe of leſſer growth, four or five inches will be ſufficient. But for farther directions, I ſhall refer to the articles of the ſeveral fruits: as alſo that of PRUNING, where theſe particulars will be ſufficiently explained.

But beſides this ſort of Eſpalier made with Aſh-poles, there is another ſort that is by many people preferred; which is framed with ſquare timbers cut to a proper ſize, according to the ſtrength thereof, or the expence the owner is willing to go to. Theſe, though they appear more ſightly, when well fixed and painted, are not of longer duration than one of the former, provided it is well made, and the poles are ſtrong which are ſet upright; nor will they anſwer the purpoſe better, though they are vaſtly more expenſive; for the greateſt beauty conſiſts in the diſpoſing of the branches of tree; which, eſpecially in ſummer, when the leaves are on, will entirely hide from the ſight the frame of the Eſpalier; therefore all expence in erecting theſe is needleſs, farther than making proviſion to ſecure the branches of the trees in a regular order.

Fruit-trees thus planted, and well managed, are much preferable to thoſe trained up in any other figure, upon ſeveral accounts; as firſt, theſe take up very little room in a garden, ſo as not to be hurtful to the plants which grow in the quarters; and, ſecondly, the fruit upon theſe are better taſted than thoſe which grow upon dwarfs, the ſun and air having freer acceſs to every part of the tree; whereby the dampneſs ariſing from the ground is ſooner diſſipated, which is of ſingular advantage to fruit-trees (as hath been already ſhewn.) And as the trees againſt an Eſpalier are kept low, and the branches being faſtened to the Eſpalier, the fruit will not be blown down ſo ſoon by the wind; ſo that upon the whole, Eſpaliers muſt be allowed to be of great uſe and beauty.

EVER-GREEN THORN. See Pyracantha.

EVERLASTING PEA. See Lathyrus.

EUGENIA. Michel. 108.

The Characters are,

The flower hath a permanent empalement of one leaf, cut into four ſegments: the flower hath four oblong obtuſe petals, twice as large as the empalement. It hath many ſtamina which are inſerted in the empalement, terminated by ſmall ſummits, and a turbinated germen ſituated under the flower, ſupporting a ſimple ſtyle the length of the ſtamina, crowned by a ſingle ſtigma. The germen afterward becomes a quadrangular plumb-ſhaped fruit crowned, having one cell incloſing one ſmooth roundiſh nut.

This genus of plants is ranged in the firſt ſection of Linnæus's twelfth claſs, intituled Icoſandria Monogynia, the flower having many ſtamina inſerted in the empalement, and one ſtyle.

The Species are,

1. Eugenia (*Malaccenſis*) foliis integerrimis, pedunculis racemoſis lateralibus. Flor. Zeyl. 187. *Eugenia with entire leaves and branching foot-ſtalks of flowers.* Jamboſa domeſtica. Rump. Amb. 1. p. 121.
2. Eugenia (*Jamboo*) foliis integerrimis, pedunculis racemoſis terminalibus. Flor. Zeyl. 188. *Eugenia with entire leaves, and branching foot-ſtalks of flowers terminiating the branches.* Jamboſa ſylveſtris alba. Rump. Amb. 1. 127.

There are ſome other ſpecies of this genus which grow naturally in India, but thoſe here mentioned are the only ſorts which I have ſeen in the Engliſh gardens. Some plants of the firſt ſort I received from Dr. Heberden with ſome other plants, which were ſent by his brother from the Braſils, where it is cultivated for the table; ſo that the plants of this kind are common in moſt parts of the Eaſt-Indies.

This riſes with a tree-like ſtem, covered with a brown bark, which, in the countries where it grows naturally, riſes from twenty to thirty feet high, ſending out many branches, garniſhed with oblong entire leaves, ending in acute points: theſe are placed oppoſite, and when young, are of a bright purple colour; but as they grow older, become of a light green. The flowers are produced on the ſide of the branches, each foot-ſtalk branching into three or four others, each ſupporting one flower. Theſe are ſucceeded by irregular-ſhaped ſucculent fruit, incloſing one nut.

The ſecond ſort riſes to the ſame height as the firſt, but the leaves are longer and narrower. The flowers do, for the moſt part, terminate the branches, though there are ſome which come on their ſides. The fruit of this is ſmaller, rounder, and not ſo much eſteemed as thoſe of the firſt.

Theſe plants are preſerved in the gardens of the curious for the ſake of variety, though there is little hopes of their producing fruit in England. They may be propagated by their ſtones, if they can be obtained freſh from the countries of their natural growth. The ſtones ſhould be planted in ſmall pots filled with light earth, and plunged into a hot-bed, obſerving to keep the earth moiſt but not wet; in about ſix weeks the plants will appear; and when grown four inches high, they ſhould be carefully ſeparated, planting each into a ſmall pot, plunging them into the hot-bed again, being careful to ſhade them till they have taken new root; after which, they ſhould be treated in the ſame way as other tender plants from the ſame country, always plunging them into the tan-bed in the ſtove; and in winter be ſparing in water to them, for much wet will kill them.

EUONYMUS. Lin. Gen. Plant. 240. Tourn. Inſt. R. H. 617. tab. 388. [Εὐώνυμος, of εὐ, good, and ὄνομα, a name; ſo called by way of antiphraſis, becauſe it is hurtful to animals.] The Spindle-tree, or Prickwood; in French, *Fuſain.*

The Characters are,

It hath a ſhort empalement to the flower of one leaf, which is divided into four or five ſegments. The flower hath four or five oval petals, which ſpread open. It hath five ſhort ſtamina, which are joined at their baſe to the germen, terminated by twin ſummits. In the center is ſituated a large oval germen, ſupporting a ſhort ſtyle, crowned by an obtuſe ſtigma. The germen afterwerd becomes a ſucculent four-cornered coloured capſule, having as many cells as angles, each containing one oval ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fifth claſs, which includes thoſe plants whoſe flowers have five ſtamina and one ſtyle.

The Species are,

1. Euonymus (*Vulgaris*) foliis lanceolatis, floribus tetrandriis, fructu tetragono. *Spindle-tree with ſpear-ſhaped leaves, flowers having four ſtamina, and quadrangular fruit.* Euonymus vulgaris, granis rubentibus. C. B. P. 428. *The common Spindle-tree.*
2. Euonymus (*Latifolius*) foliis ovato-lanceolatis, floribus pentandris, fructu pentagono, pedunculis longiſſimis. *Spindle-tree with oval ſpear-ſhaped leaves, flowers having five ſtamina, a five-cornered fruit, and very long foot-ſtalks.* Euonymus latifolius. C. B. P. 428. *Broad-leaved Spindle-tree.*
3. Euonymus (*Americanus*) floribus omnibus quinquefidis. Lin. Sp. Plant. 197. *Spindle-tree whoſe flowers are all divided into five points.* Euonymus Virginianus, pyracanthæ foliis, ſempervirens, capſulâ verrucarum inſtar aſperatâ rubente. Pluk. Phyt. 115. f. 5. *Virginian evergreen Spindle-tree with rough, warted, red ſeed-veſſels.*
4. Euonymus (*Pinnatis*) foliis pinnatis, fructu racemoſo trigono. *Spindle-tree with winged leaves, and three-cornered fruit growing in bunches.* Euonymus caudice non ramoſo, folio alato, fructu rotundo tripyreno. Sloan. Cat. Jam. 171. *Spindle-tree with an unbranching ſtalk, a winged leaf, and a round fruit having three ſeeds.*

The firſt ſort grows naturally in England. It is very common in hedges, and is ſometimes found growing in woods. This, when growing in hedges, is ſeldom ſeen of any conſiderable ſize, but rather appears like a ſhrub; but if planted ſingle, and trained up like other trees, will have a ſtrong woody ſtem, and riſe more than twenty feet high, dividing into many branehes, garniſhed with ſpear-ſhaped leaves about three inches long, and one inch and a quarter broad in the middle, gradually diminiſhing to both ends; they are entire, of a deep green colour, and are placed oppoſite. The flowers come out in ſmall bunches from the ſide of the ſtalks, ſtanding upon ſlender foot-ſtalks; they are compoſed of four whitiſh petals, which are expanded in form of a croſs. The empalement is divided into four parts. The flowers have four ſtamina, and the fruit is four-cornered, and opens into four cells. This tree flowers the latter part of May and the beginning of June, and the fruit ripens in October, at which time the ſeed-veſſels ſpread open and expoſe the ſeeds, which are of a beautiful red colour; ſo that when the branches are well ſtored with them, the trees make a good appearance at that ſeaſon, when growing among other ſorts. The wood of this tree is uſed by the muſical inſtrument-makers for toothing of organs and virginal keys; the branches are cut into tooth-pickers, and for making of ſkewers; and ſpindles are made of the wood, from whence the tree was titled Spindle-tree; but in ſome counties it is called Dogwood.

The ſecond ſort grows naturally in Auſtria and Hungary; this was very ſeldom ſeen in England till of late years, ſince I procured it from France, and from the ſeeds of thoſe plants great numbers have been ſince raiſed, ſo it is now pretty common in ſeveral of the nurſeries near London; this riſes with a ſtronger ſtem than the firſt, and grows to a larger ſize. The leaves are oval and ſpear-ſhaped, about four inches long, and two inches broad in the middle, of a light green colour, and entire; they are placed oppoſite on the branches, with ſhort foot-ſtalks. The flowers come out from the ſide of the branches, upon very ſlender foot-ſtalks, which are two inches and a half long; theſe branch out into a looſe bunch, ſo that the flowers ſtand upon ſeparate foot-ſtalks. The flowers have five petals, which at firſt are white, but afterward change to a purple colour; the empalement of the flower is divided into five parts. It hath five ſtamina, and the fruit is frequently five-cornered; the fruit is much larger than that of the common ſort, and the foot-ſtalks being weak, the fruit always hang down. Dr. Linnæus has ſuppoſed theſe to be but one ſpecies, and has taken the characters of this genus from the ſecond ſort, whoſe flowers have five ſtamina and five petals, and the fruit five corners; but all thoſe of the common ſort which I have examined have but four, and theſe differences are permanent in thoſe plants which riſe from ſeeds; for I have raiſed many of both ſorts from ſeeds, but have never found either of them alter.

The third ſort grows naturally in Virginia, Carolina, and other parts of North America; this riſes with a ſhrubby ſtalk to the height of eight or ten feet, dividing into many branches, which come out oppoſite from the joints of the ſtem; theſe are garniſhed with ſpear-ſhaped leaves, which are two inches long, and about three quarters of an inch broad in the middle, ending in acute points; they are placed oppoſite, and continue green all the year. The flowers are produced at the end of the branches, and alſo from the ſides, in ſmall cluſters, which are ſucceeded by round capſules, which are cloſely armed by rough protuberances. This flowers in July, but ſeldom produces ripe fruit in England.

As this is an evergreen ſhrub, ſo it merits a place in every curious garden, and particularly in all plantations of evergreen trees and ſhrubs; there is a variety of this with variegated leaves, which is preſerved in the nurſery-gardens.

The fourth ſort grows naturally in Jamaica, and ſome of the other iſlands in the Weſt-Indies; this riſes with an upright woody ſtalk, to the height of ten or twelve feet; at the top it divides into two or three ſhort branches, which are garniſhed by winged leaves, compoſed of ſix or ſeven pair of ſmall leaves (or lobes) about two inches long, and one inch broad; theſe leaves come out without order, ſtanding upon long foot-ſtalks. The flowers come out in cluſters from the ſide of the branches, toward their end; theſe are ſucceeded by roundiſh capſules, having a thick brown cover, which open in three cells, each containing a ſingle hard ſeed.

The two firſt ſorts may be propagated either by ſeeds, or layers; if by ſeeds, they ſhould be ſown in autumn, ſoon after they are ripe; then the plants will come up the ſpring following; but if the ſeeds are not ſown till ſpring, the plants will not appear till the following ſpring, whereby a whole year is loſt. The ſeeds ſhould be ſown upon a ſhady border, where they will ſucceed better than when they are more expoſed to the ſun. When the plants come up, they will require no other care but to keep them clean from weeds till the following autumn, when, as ſoon as their leaves decay, the plants ſhould be taken up and tranſplanted into a nurſery, in rows two feet diſtant, and the plants one foot aſunder in the rows; in this place they may remain two years, and then they may be removed to the places where they are to remain.

When theſe are propagated by layers, the young ſhoots ſhould be laid down in antumn; and if the joint which is laid deepeſt in the ground is ſlit, as is practiſed for Carnations, it will cauſe them to put out roots much ſooner than they otherwiſe would do; theſe layers will be ſufficiently rooted in one year to bear tranſplanting, when they ſhould be taken from the old plants, and treated in the ſame way as the ſeedlings. The cuttings of theſe ſorts, planted in a ſhady border, will take root, but they ſhould be planted in autumn, as ſoon as their leaves begin to fall; they ſhould be the ſhoots of the ſame year, with a knot of the former year at bottom.

The third ſort, which grows naturally in North America, is ſo hardy as rarely to ſuffer by cold in England, provided it is not planted in places very much expoſed. This may be propagated by laying down the young branches in the autumn, obſerving to tongue them in the ſame manner as is practiſed in laying of Carnations: theſe will have made good roots in one year, when they may be cut from the old plants, and planted in a nurſery for two years to get ſtrength; after which, they ſhould be planted where they are deſigned to remain.

The fourth ſort is a native of warmer countries, ſo cannot be preſerved in England, unleſs it is placed in a ſtove in winter: this is generally propagated by ſeeds, which muſt be ſown in pots, and plunged into a hot-bed; and when the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, and plunged into the hot-bed again, being careful to ſhade them until they have taken new root; after which they muſt be treated in the ſame way as other tender plants of the ſame countries. This ſort may alſo be propagated by cuttings during any of the ſummer months.

EUPATOROIPHALACRON. See VERBESINA.

EUPATORIUM. Lin. Gen. Plant. 842. Tourn. Inſt. R. H. 455. tab. 259. [Εὐπατώριον, of king Eupator, who firſt brought this plant into uſe.] Hemp Agrimony; in French, *Eupatoire*.

The CHARACTERS are,

It hath a compound flower, compoſed of ſeveral hermaphrodite florets, which are funnel-ſhaped, cut into five parts at the brim, which ſpread open; theſe are included in one common ſcaly empalement, whoſe ſcales are narrow, erect, and unequal. The florets have each five ſhort hairy ſtamina, terminated by cylindrical ſummits. In the bottom is ſituated a ſmall germen, ſupporting a long ſlender ſtyle, which is bifid, crowned by a narrow ſtigma. The germen afterward becomes an oblong ſeed, crowned with down, ſitting in the empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, which includes thoſe plants with compound flowers, which have only hermaphrodite fruitful flowers.

The SPECIES are,

1. EUPATORIUM (*Cannabinum*) foliis digitatis. Hort. Cliff. 396. *Eupatorium with fingered leaves.* Eupatorium cannabinum. C. B. P. 320. *Common Hemp Agrimony.*
2. EUPATORIUM (*Maculatum*) foliis lanceolato-ovatis, ſerratis, petiolatis, caule erecto. Hort. Cliff. 396. *Eupatorium with ſpear-ſhaped oval leaves which are ſawed, having foot-ſtalks, and an upright ſtalk.* Eupatorium Novæ Angliæ, urticæ foliis, floribus purpuraſcentibus, maculato caule. H. L. *New England Hemp Agrimony with Nettle leaves, purpliſh flowers, and ſpotted ſtalks.*
3. EUPATORIUM (*Purpureum*) foliis ſubverticillatis, lanceolatis ſerratis petiolatis rugoſis. Lin. Sp. Plant. 838. *Eupatorium with leaves placed in whorls, which are ſpear-*

ſpear-ſhaped, ſawed, rough, and have foot-ſtalks. Eupatorium folio oblongo rugoſo, caule purpuraſcente. Tourn. Inſt. 456. *Canada Hemp Agrimony with a long rough leaf, and purpliſh ſtalk.*

4. Eupatorium (*Scandens*) caule volubili, foliis cordatis dentatis acutis. Hort. Cliff. 396. *Eupatorium with a twining ſtalk and heart-ſhaped leaves, which are ſharply indented.* Eupatorium Americanum ſcandens, haſtato magis acuminato folio. Vaill. Mem. 1719. *Climbing American Hemp Agrimony, with a ſpear-like ſharp-pointed leaf.*

5. Eupatorium (*Rotundifolium*) foliis ſeſſilibus diſtinctis ſubrotundo-cordatis. Lin. Sp. Plant. 837. *Eupatorium with roundiſh heart-ſhaped leaves ſitting cloſe to the ſtalks, and are diſtinct.* Eupatorium Americanum, foliis rotundioribus abſque pediculis. Vaill. Mem. 1719. *American Hemp Agrimony with round leaves, having no foot-ſtalks.*

6. Eupatorium (*Fruticoſum*) foliis oblongo-cordatis, floribus paniculatis, caule fruticoſo ſcandente. *Eupatorium with oblong heart-ſhaped leaves, paniculated flowers, and a climbing ſhrubby ſtalk.* Eupatorium ſcandens, foliis ſubrotundis lucidis, floribus ſpicatis albis. Houſt. MSS. *Climbing Hemp Agrimony with roundiſh ſhining leaves, and white flowers growing in ſpikes.*

7. Eupatorium (*Odoratum*) foliis ovatis, obtuſe ſerratis petiolatis trinerviis, calycibus ſimplicibus. Lin. Sp. Plant. 839. *Eupatorium with oval, obtuſe, ſawed, three-veined leaves, having foot-ſtalks, and ſingle empalements to the flowers.* Eupatorium Americanum, teucrii folio, flore niveo. Vaill. Mem. Acad. Scien. *American Hemp Agrimony with a Tree Germander leaf, and a white flower.*

8. Eupatorium (*Perfoliatum*) foliis connatis tomentoſis. Hort. Cliff. 396. *Eupatorium with woolly leaves joined at their baſe.* Eupatorium Virginianum, ſalviæ foliis longiſſimis acuminatis, perfoliatum. Pluk. Alm. *Virginian perfoliate Hemp Agrimony, with long Sage-like leaves cloſely ſurrounding the ſtalk.*

9. Eupatorium (*Betonicifolium*) foliis oblongis, obtuſis, crenatis, glabris, calycibus ſimplicibus. *Eupatorium with oblong, obtuſe, ſmooth, crenated leaves, and ſingle empalements to the flowers.* Eupatorium betonicæ folio glabro & carnoſo, flore cœruleo. Houſt. MSS. *Hemp Agrimony with a fleſhy ſmooth Betony leaf, and a blue flower.*

10. Eupatorium (*Morifolium*) foliis cordatis ſerratis caule erecto arboreo. *Eupatorium with heart-ſhaped ſawed leaves, and an upright tree-like ſtalk.* Eupatorium Americanum arboreſcens, mori folio, floribus albicantibus. Houſt. MSS. *Tree-like American Hemp Agrimony, with a Mulberry leaf and white flowers.*

11. Eupatorium (*Punctatum*) foliis ovatis petiolatis integris, caule fruticoſo ramoſo, calycibus ſimplicibus. *Eupatorium with oval entire leaves having foot-ſtalks, a branching ſhrubby ſtalk, and ſingle empalements to the flowers.* Eupatorium Americanum fruteſcens, balſaminæ lutæ foliis, nigris maculis punctatis. Houſt. MSS. *American ſhrubby Hemp Agrimony, with yellow Balſamine leaves ſpotted with black.*

12. Eupatorium (*Hyſſopifolium*) foliis lanceolato-linearibus trinerviis ſub integerrimis. Lin. Sp. Plant. 836. *Eupatorium with narrow, ſpear-ſhaped, entire leaves, having three nerves.* Eupatorium Virginianum, folio anguſto floribus albis. Hort. Elth. 141. tab. 115. f. 140. *Virginia Hemp Agrimony, with a narrow leaf, and white flowers.*

13. Eupatorium (*Ramoſum*) foliis lanceolato-linearibus acutis, ſupernè ſerratis caule ramoſo. *Hemp Agrimony with narrow, ſpear-ſhaped, pointed leaves, ſawed on their upper part, and a branching ſtalk.*

14. Eupatorium (*Conyzoides*) foliis cordatis acutis, dentatis, trinerviis, caule fruiticoſo ramoſo. *Eupatorium with pointed, heart-ſhaped, ſawed leaves, having three veins, and a branching ſhrubby ſtalk.* Conyza fruticoſa, folio haſtato, flore pallidè purpureo. Sloan. Cat. Jam. 124. *Shrubby Fleabane with a ſpear-ſhaped leaf, and a pale purple flower.*

15. Eupatorium (*Paniculatum*) foliis cordatis rugoſis crenatis, caule paniculato. *Eupatorium with rough, heart-ſhaped, crenated leaves, and a paniculated ſtalk.* Conyza Salviæ foliis conjugatis, floribus ſpicatis rubentibus. Houſt. MSS. *Fleabane with Sage leaves placed oppoſite, and red flowers growing in ſpikes.*

16. Eupatorium (*Houſtonis*) foliis cordatis acuminatis, caule volubili, floribus ſpicatis racemoſis. *Eupatorium with heart-ſhaped pointed leaves, a twining ſtalk, and branching ſpiked flowers.* Eupatorium Americanum, ſcandens, folio haſtato glabro, floribus ſpicatis. Houſt. MSS. *Climbing American Hemp Agrimony with a ſmooth ſpear-ſhaped leaf, and ſpiked flowers.*

17. Eupatorium (*Trifoliatum*) foliis ternis. Flor. Virg. 119. Lin. Sp. Plant 838. *Hemp Agrimony with trifoliate leaves.*

18. Eupatorium (*Altiſſimum*) foliis lanceolatis nervoſis, inferioribus extimo ſub ſerratis, caule fruticoſo. Hort. Upſal. 152. *Eupatorium with nervous ſpear-ſhaped leaves, whoſe lower leaves are ſawed on their edges, and ſtand in whorls round the ſtalks.* Eupatorium folio oblongo, rugoſo, ampliori, caule vireſcente. Tourn. Inſt. R. H. 456. *Hemp Agrimony with a large, oblong, rough leaf, and a green ſtalk.*

19. Eupatorium (*Cæleſtinum*) foliis cordato-ovatis, obtuſe ſerratis petiolatis, calycibus multifloris. Lin. Sp. Plant. 838. *Eupatorium with heart-ſhaped oval leaves obtuſely ſawed, having foot-ſtalks, and many flowers to the empalements.* Eupatorium ſcorodoniæ folio, flore cæruleo. Hort. Elth. 140. tab. 114. *Hemp Agrimony with a Wood Sage leaf, and a blue flower.*

The laſt grows naturally in Carolina, from whence the late Dr. Dale ſent me the ſeeds; theſe plants flowered very finely the year after they were raiſed, but never have flowered ſince, for the roots creep greatly in the ground, but never ſend up any ſtalks.

The firſt ſort grows naturally by the ſide of rivers and ditches in moſt parts of England, and is the only ſpecies of this genus, which is known to grow naturally in Europe; this is eſteemed as a very good vulnerary herb, ſo ſtands in the liſt of medicinal plants. It is ſeldom admitted into gardens, becauſe, wherever it is ſuffered to ſeed, the ground will be well ſtored with the plants to a great diſtance.

The ſecond ſort grows naturally in ſeveral parts of North America, from whence it has been introduced to the gardens in Europe; this hath a perennial root, but an annual ſtalk, which riſes about two feet and a half high; it is purple, and has many dark ſpots upon it. The leaves are rough, oval and ſpear-ſhaped, having foot-ſtalks; they are placed by threes round the ſtalk toward the bottom, but upward by pairs oppoſite at each joint. The ſtalks are terminated by cluſters of purple flowers, growing in a ſort of corymbus; theſe come out in July and Auguſt, and in warm ſeaſons will ripen its ſeeds in autumn.

The third ſort grows naturally in North America; this riſes with an upright ſtalk near four feet high, garniſhed with long, narrow, ſpear-ſhaped leaves at each joint; theſe are deeply ſawed on their edges, and the midrib is oblique to the foot-ſtalk; they are placed by fours round the ſtalk in whorls, and are of a dark green colour. The ſtalks are terminated by bunches of purple flowers like the laſt, which appear at the ſame time. This hath a perennial root and an annual ſtalk.

The fourth ſort grows naturally in Virginia and Carolina; this hath a perennial root, which ſends out many twining ſtalks in the ſpring; theſe twiſt about any neighbouring ſupport, and riſe to the height of five or ſix feet, garniſhed at each joint with two heart-ſhaped leaves, which are indented on their edges, and terminate in acute points; at each joint there are two ſmall ſide branches come out, which are terminated by cluſters of white flowers, ſo that the ſtalks ſeem covered with them moſt part of their length; but as theſe come pretty late in the ſeaſon, ſo unleſs the ſummers prove warm, the plants do not flower well in England.

There is another of theſe plants with purple flowers, ſtanding upon longer foot-ſtalks, which was ſent me from Campeachy; but the ſtalks and leaves are very like thoſe of this ſort, ſo that I doubt whether it be a diſtinct ſpecies.

The fifth ſort grows naturally in New England and Virginia, from both of theſe counties I have received the ſeeds; this hath a perennial root and an annual ſtalk; it riſes with upright ſtalks about a foot high; theſe have their joints pretty near each other, where they are garniſhed with roundiſh heart-ſhaped leaves, ſitting cloſe to the ſtalks; they are ſawed on their edges, and are of a light green colour. The flowers are produced in ſmall looſe panicles at the top of the ſtalks; they are white, and have two ſmall green leaves immediately under the flowers. Theſe flowers appear the latter end of June, but the ſeeds ſeldom ripen in England.

The ſixth ſort grows naturally at La Vera Cruz in America, from whence the late Dr. Houſton ſent me the ſeeds; this hath a ſhrubby climbing ſtalk, which riſes to the height of ten or twelve feet, faſtening itſelf to any neighbouring prop for ſupport, and is garniſhed with heart-ſhaped leaves, placed oppoſite; they are about three inches long, and one and a half broad, of a lucid green; the flowers come out in long branching panicles, which proceed from the ſide of the ſtalks, and are terminated by a branching panicle of white flowers. This ſort is tender, ſo will not live in this country without artificial heat.

The ſeventh ſort riſes with upright ſtalks three feet high, garniſhed with oval leaves at each joint, which are placed oppoſite; they have very ſhort foot-ſtalks, and are ſawed on their edges; from the ſides of the ſtalks, at every joint, is produced two ſlender branches, which ſtand erect; theſe, and the principal ſtalks alſo, are terminated by cluſters of white flowers; they appear in Auguſt and September, and the ſtalks decay in winter, but the root is perennial. This grows naturally in Penſylvania, and other parts of America.

The eighth ſort grows naturally in Virginia and Philadelphia; this hath a perennial root and an annual ſtalk. The ſtalks riſe from two to three feet high; they are hairy, and garniſhed with rough leaves at each joint, which are from three to four inches long, and about an inch broad at their baſe, gradually leſſening to a very acute point; the two leaves are joined at their baſe, ſo the ſtalks ſeem to grow through them; they are of a dark green, and are covered with ſhort hairs. The upper part of the ſtalk divides into many ſlender foot-ſtalks, each ſuſtaining a cloſe cluſter of white flowers. Theſe come out in July, and in warm ſeaſons the ſeeds will ſometimes ripen in England.

The ninth ſort grows naturally at La Vera Cruz, from whence the late Dr. Houſtoun ſent me the ſeeds; this riſes with an upright ſtalk near two feet high, garniſhed toward the bottom with oblong obtuſe leaves, which are of a thick ſubſtance, and crenated on their edges; the upper part of the ſtalk is naked to the top, where the flowers come out in a thick panicle; they are blue, and have ſingle empalements. This flowers late in autumn, but never ripens ſeeds here; the root is biennial, and periſhes ſoon after it has flowered.

The tenth ſort was ſent me by the late Dr. Houſtoun from La Vera Cruz, where he found it growing naturally; this hath a thick woody ſtalk, which riſes twelve or fourteen feet high, ſending out many branches, which are channelled, and covered with a brown bark, garniſhed with regular heart-ſhaped leaves as large as thoſe of the Mulberry-tree; they are of a light green colour, and ſawed on their edges, placed oppoſite upon foot-ſtalks, near two inches long; the upper part of the branches are terminated by four or five pair of foot-ſtalks, which come out oppoſite from the joints, and the top is terminated by an odd one; theſe ſuſtain branching panicles of white flowers, which together form a long looſe pyramidal thyrſe, and make a fine appearance, for there are no leaves intermixed with the flowers, but ſo far as the ſpike reaches the ſtalks are naked. This ſort has flowered in the Chelſea garden, but did not produce ſeeds.

The eleventh ſort grows naturally at La Vera Cruz, from whence the late Dr. Houſtoun ſent it me; this riſes with many ſhrubby ſtalks near five feet high, which divide into many ſlender branches, whoſe joints are three or four inches aſunder; at each of theſe come out two oval leaves about three quarters of an inch long, and half an inch broad, ſtanding upon long ſlender foot-ſtalks; they have ſeveral black ſpots on their ſurface. The branches come out horizontal, and are terminated by ſmall bunches of white flowers, whoſe empalements are ſingle, and compoſed of ſeven narrow ſpear-ſhaped leaves, which are divided to the bottom.

The twelfth ſort riſes with an upright round ſtalk to the height of three feet, ſending out ſeveral branches toward the top, which come out regularly by pairs; they are garniſhed with leaves, placed by pairs; theſe are two inches and a half long, and about one third of an inch broad, having three longitudinal veins; they are of a light green colour, and entire. The flowers ſtand upon long foot-ſtalks at the end of the branches, ſome ſuſtaining one, ſome two, and others three or four flowers; they are white, and appear late in autumn. This grows naturally in Carolina.

The thirteenth ſort grows naturally in Maryland; this hath a perennial root and an annual ſtalk, which riſes three feet high, dividing upward into many branches, which are cloſely garniſhed with narrow ſpear-ſhaped leaves, which are from two to three inches long, and a quarter of an inch broad, of a deep green, ſitting cloſe to the branches; they have three longitudinal veins, and their upper part ſharply ſawed on their edges, ending in acute points. The branches are terminated by roundiſh cluſters of white flowers, which appear in Auguſt, and continue till October; and in warm ſeaſons they are ſucceeded by ſeeds, which ripen here.

The fourteenth ſort grows naturally in Jamaica, and in moſt of the other iſlands in the Weſt-Indies; this riſes with ſhrubby ſtalks about ſix or ſeven feet high, dividing into many branches, which are garniſhed with heart-ſhaped leaves, ending in acute points, indented on their edges, having three longitudinal veins; the upper part of the branches are terminated by ſlender foot-ſtalks, each ſuſtaining a ſmall cluſter of white flowers, included in oblong ſcaly empalements of a ſilvery colour.

The fifteenth ſort was ſent me from La Vera Cruz by the late Dr. Houſtoun; this riſes with an upright branching ſtalk three feet high, ſending out two ſide branches from every joint, almoſt the whole length, which are terminated by looſe ſpikes of red flowers, as is alſo the principal ſtalk. The leaves are heart-ſhaped, rough, and are crenated on their edges, ſitting cloſe to the ſtalks; they are of a light green, and a little hoary.

The ſixteenth ſort was ſent me from Jamaica by the late Dr. Houſtoun; this hath ſlender twining ſtalks, which faſten themſelves to any neighbouring ſupport, and riſe eight or ten feet high, ſending out ſmall branches oppoſite, at moſt of the upper joints. The leaves on the lower part of the ſtalk are heart-ſhaped, ending in acute points; the upper leaves are almoſt triangular, they are ſmooth, and of a lucid green; the upper part of the ſtalks have long branching ſpikes of white flowers, which are ſmall, and ſit cloſe to the foot-ſtalks.

The ſeventeenth ſort grows naturally in Penſylvania; this hath a perennial root, from which ariſe ſeveral upright ſtalks, which grow to the height of ſeven or eight feet, in a moiſt ſoil, or where they are ſupplied with water in dry weather, and are garniſhed with oval, rough, ſpear-ſhaped leaves, which are a little ſawed on their edges; they are placed in whorls round the ſtalks, ſometimes ſeven, at other places four or five of theſe ſtand at each joint; they are about three inches long, and two inches broad. The ſtalks are terminated by a looſe corymbus of purple flowers, which appear in Auguſt and continue till October, but are not ſucceeded by ſeeds in England.

The eighteenth ſort riſes with a ſingle, upright, green ſtalk, about four feet high, garniſhed at each joint by four ſpear-ſhaped leaves, placed in whorls round the ſtalks; they are ſix inches long, and two inches broad in the middle, leſſening to both ends, terminating in acute points; they are rough, ſawed on their edges, and ſtand on ſhort foot-ſtalks; the ſtalk is terminated by a cloſe corymbus of purple flowers, which appear in July, and continue till September. The root is perennial, but the ſtalks decay every winter; it grows naturally in North America.

The nineteenth ſort grows naturally in Carolina; this hath a creeping root, which ſpreads and multiplies very faſt. The ſtalks riſe about two feet high; they are garniſhed with oval heart-ſhaped leaves, which have foot-ſtalks, and are ſawed on their edges. The flowers are produced at the top of the ſtalks in a ſort of corymbus; they are of a fine blue colour, but the roots ſpread ſo much as to cauſe barrenneſs of flowers after the firſt year.

All theſe ſorts may be propagated by ſeeds; ſeveral of them ripen their ſeeds in England; theſe ſhould be ſown in autumn as ſoon as they are ripe, for then the plants will come up the following ſpring; but if they are kept out of the ground till ſpring, the plants will not come up till the year after; and thoſe ſeeds which are procured from America ſhould be ſown as ſoon as they arrive, for though they may not grow the firſt year, yet there will be a greater certainty of their ſucceeding, than when they are kept longer out of the ground.

The ſecond, third, fifth, ſeventh, eighth, twelfth, thirteenth, ſeventeenth, eighteenth, and nineteenth ſorts are hardy plants, ſo the ſeeds of theſe may be ſown in the full ground, but there muſt be care taken in the ſowing to keep the ſorts ſeparate; for as the ſeeds of theſe plants have a light down adhering to them, they are eaſily diſplaced by the leaſt wind; ſo that the beſt way will be to ſow them in drills, but theſe ſhould be but ſhallow, for if the ſeeds are buried too deep they will not grow. The bed in which theſe are ſown ſhould not be too much expoſed to the ſun, but rather have an eaſt aſpect, where the morning ſun only reaches it; but where it is more expoſed, it ſhould be ſhaded with mats in the heat of the day, and the ground ſhould be kept pretty moiſt; for as theſe plants generally grow in moiſt ſhady ſituations in their native countries, they will ſucceed better when they have a ſoil and ſituation ſomewhat like that; though as we want their heat in ſummer, the plants will thrive here when expoſed to the ſun, provided they have a moiſt ſoil, or are ſupplied with water in dry weather.

When the young plants come up, they muſt be kept clean from weeds; and where they are too cloſe, ſome of them ſhould be drawn out, to give room for the others to grow; and if theſe are wanted, they may be planted in another bed, where, if they are ſhaded and watered, they will ſoon take root; after which they will require no farther care but to keep them clean from weeds till the following autumn, when they may be tranſplanted to the places where they are to remain. As the roots of theſe plants ſpread out to a conſiderable diſtance, they ſhould not be allowed leſs than three feet from any other plants, and ſome of the largeſt growing ſhould be allowed four feet. If the ſoil in which they are planted is a ſoft gentle loam, they will thrive much better, and flower ſtronger than in light dry ground; in which, if they are not duly watered in dry ſummers, their leaves will ſhrink, and their ſtalks will not grow to half their uſual height.

All theſe ſorts have perennial roots, by which they may be propagated; for as ſome of them do not perfect their ſeeds in England, ſo that is the only way of increaſing the plants here; ſome of the ſorts have creeping roots, ſending out offſets in great plenty, ſo theſe are eaſily propagated; and the others may be taken up, or the heads taken off from them every other year, in doing of which there ſhould be care taken not to cut or injure the old plants too much, which would cauſe them to flower weak the following year. The beſt time to remove theſe plants is in autumn, as ſoon as they have done growing, that they may get freſh roots before the froſt comes on; but if that ſhould happen ſoon after their removal, if the ſurface of the ground is covered with tan, or dried leaves, to keep out the froſt, it will effectually ſecure them; and if this is done to the old plants in very ſevere winters, it will always preſerve them; but the nineteenth ſort is the only one which I have known killed by froſt: however, it may not be amiſs to practiſe this on the young ſeedling plants, which have not ſo good roots, nor are ſo well eſtabliſhed in the ground; the future culture will be only to dig the ground about them every ſpring, and keep them clean.

The fourth ſort ſends out many weak twining ſtalks, which require ſupport; ſo there ſhould be ſome ſtakes fixed down by their roots in the ſpring when they begin to ſhoot, to which the young ſtalks ſhould be led and faſtened, and afterward they will naturally twine round them and riſe four or five feet high if they are ſupplied with water, and in warm ſeaſons they will produce plenty of white flowers in Auguſt. This ſort is ſometimes killed in very ſevere winters, if they are not covered; but if, when the ſtalks decay in the autumn, the ground about them is covered with ſome old tanners bark, it will effectually ſecure the roots. This ſort multiplies very faſt by its creeping roots, which may be parted every other year.

The ſixth and ſixteenth ſorts have twining ſlender ſtalks, which require to be ſupported in the like manner; but theſe are natives of warm countries, ſo they will not thrive in England, unleſs they are placed in a warm ſtove; therefore they ſhould be planted in pots and plunged into the tan-bed in the ſtove, where, if they are ſupplied with wet in hot weather, they will thrive and produce flowers. The ſixth ſort hath ſhrubby ſtalks, and does not propagate by the root, ſo there ſhould be layers made of the young branches, which will put out roots if they are properly ſupplied with water; but the ſixteenth ſort may be propagated by parting the roots, in the ſame manner as the fourth ſort.

The ninth and fifteenth ſorts have perennial roots, but their ſtalks decay every winter. Theſe are tender plants, ſo ſhould be planted in pots, and kept conſtantly plunged in the tan-bed in the ſtove, where they will thrive and flower. Theſe may be propagated by cutting off ſome of their young ſhoots about the middle of June, when they have ſtrength, and planted into pots filled with light earth, and plunged into a moderate hot-bed, where, if they are ſhaded from the ſun, and gently watered as they may require it, they will put out roots in ſix weeks, and may then be tranſplanted into ſeparate pots, and treated as the old plants.

The tenth, eleventh, and fourteenth ſorts have ſhrubby ſtalks, which are perennial. Theſe are natives of warm countries, ſo will not thrive in England out of a ſtove; therefore they ſhould be planted in pots and kept plunged in the tan-bed of the ſtove, and treated as the former ſorts. Theſe will ſometimes take root from cuttings, but not very freely, ſo that the beſt way is from ſeeds when they can be procured.

When the ſeeds of theſe tender ſorts can be had from their native countries, the plants raiſed that way are much preferable to thoſe which are obtained by any other method, and will flower much ſtronger, therefore ſhould be preferred; but as theſe ſeeds ſeldom grow the firſt year, few perſons have patience enough to wait for the plants coming up. When any of theſe ſeeds are brought over, they ſhould be ſown as ſoon as they arrive in pots, that they may be removed at any time; the pots ſhould be plunged into a moderate hot-bed, and the earth kept tolerably moiſt; the glaſſes ſhould alſo be ſhaded in the heat of the day, to prevent the earth from drying; in this hot-bed the pots may remain till autumn, when, if the plants are not up, they ſhould be plunged between the plants in the bark-ſtove, and in the ſpring removed to a gentle hot-bed, which will bring up the plants ſoon after. When theſe are fit to remove they ſhould be planted in ſeparate ſmall pots, and plunged into the hot-bed again, ſhading them from the ſun till they have taken new root; then they ſhould have a large ſhare of free air admitted to them in warm weather, and frequently refreſhed with water.

In the winter theſe plants ſhould be more ſparingly watered, eſpecially thoſe ſorts whoſe ſtalks decay; and in the ſummer they ſhould have a large ſhare of free air admitted to them, with which management they will thrive and flower.

EUPHORBIA. Lin. Gen. Plant. 536. Euphorbium. Boer. Ind. alt. 1. 258. Tithymalus. Tourn. Inſt. R. H. 85. tab. 18. The Burning Thorny Plant.

This plant was named Euphorbia by King Juba, the father of Ptolemy, who governed both the Mauritanias; whoſe phyſician was named Euphorbus, and his brother Antonius Muſa is ſaid to have healed Auguſtus with this plant.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is ſwelling, rough, and divided into five parts at the brim. The flower hath four or five thick truncated petals, and twelve or more ſtamina which are inſerted in the receptacle; they are longer than the petals, and are terminated by globular ſummits. In the center is ſituated a three-cornered germen, ſupporting three bifid ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes a roundiſh capſule with three cells, each containing one roundiſh ſeed.

This genus of plants is ranged in the third ſection of Linnæus's eleventh claſs, which includes the plants whoſe flowers have twelve ſtamina and three ſtyles. To this genus he has added the Tithymalus and Tithymaloides of Tournefort and others. The difference between the Euphorbium and Tithymalus, conſiſts more in their outward form, than in the characters of either flower or fruit, ſo may be properly enough joined together; but the flower of Tithymaloides being very different in its form, ſhould be ſeparated from them, therefore I ſhall place them under the title of Tithymalus; and as the number of Tithymali is very great, many of which are common weeds, I ſhall ſelect only the more rare or uſeful kinds to enumerate here.

The SPECIES are,

1. EUPHORBIA (*Antiquorum*) aculeata triangularis ſubnuda articulata, ramis patentibus. Lin. Hort. Cliff. 196. *Euphorbia with triangular jointed ſtalks which are naked, and have ſpines and ſpreading branches.* Euphorbium verum antiquorum. Hort. Amſt. 1. p. 23. *Prickly triangular-pointed Euphorbia, with ſpreading branches, commonly called the true Euphorbium of the ancients.*

2. EUPHORBIA (*Canarienſis*) aculeata nuda ſubquadangularis, aculeis geminatis. Hort. Cliff. 196. *Euphorbia with naked ſtalks, which have four angles and double ſpines.* Euphorbium tetragonum & pentagonum ſpinoſum Canarinum. Boerh. Ind. alt. 1. 258. *Canary Euphorbium with four or five angles which have ſpines.*

3. EUPHORBIA (*Trigonum*) aculeata nuda triangularis articulata, ramis erectis. *Thorny-jointed triangular Euphorbia with upright naked branches.* Euphorbium trigonum & tetragonum ſpinoſum, ramis compreſſis. D'Iſnard. Act. Par. 1720. *Prickly Euphorbium having three and four angles with compreſſed branches.*

4. EUPHORBIA (*Officinarum*) aculeata nuda multangularis, aculeis geminatis. Lin. Hort. Cliff. 196. *Thorny Euphorbia having many angles and ſpines growing by pairs.* Euphorbium cerei effigie caulibus craſſioribus, ſpinis validioribus armatum. Hort. Amſt. 1. p. 21. *Torch-ſhaped Euphorbium, with thick ſtalks armed with ſtrong ſpines.*

5. EUPHORBIA (*Neriifolia*) aculeata ſeminuda, angulis obliquè tuberculatis. Lin. Hort. Cliff. 196. *Thorny half-naked Euphorbia with oblique tubercular angles, commonly called the Oleander-leaved Euphorbium.* Euphorbium anguloſum, foliis nerii latioribus. Boerh. Ind. alt. 1. 258. *Angular Euphorbium, with broad Oleander leaves.*

6. EUPHORBIA (*Heptagona*) aculeata nuda, ſeptem-angularis, ſpinis ſolitariis ſubulatis floriferis. Lin. Hort. Cliff. 196. *Naked ſeptangular thorny Euphorbia, with ſingle awl-ſhaped ſpines, producing flowers at their extremities.* Euphorbium heptagonum, ſpinis longiſſimis in apice fructiferis. Boerh. Ind. alt. 1. 258. *Euphorbium with ſeven angles and very long ſpines, bearing fruit at their tops.*

7. EUPHORBIA (*Caput Meduſæ*) inermis tuberculis imbricatis, foliolo lineari inſtructis. Lin. Hort. Cliff. 197. *Euphorbia without thorns, cloſely covered with tubercles lying over each other like tiles, and narrow leaves, commonly called Meduſa's Head.* Euphorbium Afrum, caule craſſo ſquamoſo, ramis in capitis Meduſæ ſpeciem cincto. Boerh. Ind. alt. 258. *African Euphorbium with a thick ſcaly ſtalk, and branches diſpoſed like Meduſa's head.*

8. EUPHORBIA (*Mamillaris*) aculeata nuda, angulis tuberoſis, ſpinis interſtinctis. Lin. Sp. Plant. 451. *Naked prickly Euphorbia, with tuberous angles having ſpines growing between them.* Euphorbium polygonum aculeis longioribus ex tuberculorum internodiis prodeuntibus. D'Iſnard. Act. Par. 1720. *Euphorbium with many angles, and long ſpines growing out from between the knots.*

9. EUPHORBIA (*Cereiformis*) aculeata nuda, multangularis, ſpinis ſolitariis ſubulatis. Prod. Leyd. 195. *Naked thorny Euphorbia with many angles, and ſingle awl-ſhaped ſpines.* Euphorbium cerei effigie, caulibus gracilioribus. Boerh. Ind. alt. 1. 258. *Euphorbium with the appearance of Torch Thiſtle, and a ſlender ſtalk.*

10. EUPHORBIA (*Fructus Pini*) inermis imbricata tuberculis foliolo lineari inſtructis. Hort. Cliff. 197. *Imbricated Euphorbia without ſpines, having tubercles furniſhed with very narrow leaves.* Euphorbium Afrum, facie fructûs pini. Boerh. Ind. alt. 1. 258. *African Euphorbium with the appearance of Pine fruit, commonly called Little Meduſa's Head.*

11. EUPHORBIA (*Patula*) inermis, ramis patulis ſimplicibus teretibus, foliolis linearibus inſtructis. *Euphorbia without ſpines, having ſingle ſpreading branches which are taper, terminated with very narrow leaves.*

12. EUPHORBIA (*Procumbens*) inermis ramis teretibus procumbentibus tuberculis quadragonis. *Euphorbia without ſpines, having trailing branches with quadrangular tubercles.*

13. EUPHORBIA (*Inermis*) inermis, ramis plurimis procumbentibus, ſquamoſis, foliolis deciduis. *Euphorbia without ſpines, having many trailing branches which are ſcaly, and deciduous leaves.*

14. EUPHORBIA (*Tiruaculii*) inermis fruticoſa ſubnuda filiformis erecta, ramis patulis determinatè confertis. Lin. Hort. Cliff. 197. *Shrubby erect Euphorbia without ſpines, and ſlender ſpreading branches terminating in cluſters, commonly called Indian-tree Spurge.* Tithymalus Indicus fruteſcens. Hort. Amſt. 1. p. 27. *Indian ſhrubby Spurge.*

15. EUPHORBIA (*Viminalis*) inermis fruticoſa nuda filiformis volubilis, cicatricibus oppoſitis. Hort. Cliff. 197. *Shrubby naked Euphorbia without ſpines, and ſlender twining branches, commonly called Indian Climbing Spurge.* Tithymalus Indicus vimineus penitus aphyllos. *Indian Spurge with ſlender branches, entirely without leaves.*

16. EUPHORBIA (*Mauritanica*) inermis fruticoſa ſeminuda filiformis flaccida, foliis alternis. Lin. Hort. Cliff. 197. *Naked ſhrubby Euphorbia without ſpines, taper flaccid branches, and leaves placed alternately.* Tithymalus aphyllus Mauritania. Hort. Elth. 384. *Mauritanian Spurge without leaves.*

17. EUPHORBIA (*Cotinifolia*) foliis oppoſitis ſubcordatis petiolatis emarginatis integerrimis, caule fruticoſo. Lin. Sp. Plant. 453. *Euphorbia with heart-ſhaped leaves placed oppoſite upon foot-ſtalks, which are indented at the top, entire, and a ſhrubby ſtalk.* Tithymalus arboreus Americanus cotini folio. Hort. Amſt. 1. p. 29. *Tree American Spurge with a Venice Sumach leaf.*

18. EUPHORBIA (*Lathyris*) umbellâ quadrifidâ, dichotomâ, foliis oppoſitis integerrimis. Lin. Sp. Plant. 457.

457. *Euphorbia with a quadrifid umbel, a forked ſtalk, and entire leaves placed oppoſite.* Tithymalus latifolius Cataputia dictus. H. L. *Broad-leaved Spurge, called Cataputia.*

19. Euphorbia (*Myrſinites*) umbellâ ſuboctifidâ, bifida, involucellis ſubovatis, foliis ſpathulatio patentibus carnoſis mucronatis margine ſcabris. Lin. Sp. Plant. 461. *Euphorbia with an umbel divided into eight points, whoſe ſmall involucrums are oval, and ſpreading fleſhy-pointed leaves ſhaped like a ſpatula, having rough borders.* Tithymalus myrſinites latifolius. C. B. P. 296. *Broad-leaved Myrtle Spurge.*

20. Euphorbia (*Dendroides*) umbellâ multifidâ, dichotomâ, involucellis ſubcordatis, primariis triphyllis, caule arboreo. Lin. Sp. Plant. 462. *Euphorbia with a multifid forked umbel, heart-ſhaped ſmall involucrums, the firſt three-leaved, and a tree-like ſtalk.* Tithymalus myrtifolius arboreus. C. B. P. 290. *Myrtle-leaved Tree Spurge.*

21. Euphorbia (*Amygdaloides*) umbellâ multifidâ, dichotomâ, involucellis perfoliatis emarginatis, orbiculatis foliis obtuſis. Lin. Sp. Plant. 662. *Euphorbia with a multifid umbel divided by pairs, orbicular perfoliate involucrums, and obtuſe leaves.* Tithymalus characias amygdaloides. C. B. P. 290. *Wood Spurge.*

22. Euphorbia (*Paluſtris*) umbellâ multifidâ, ſubtrifidâ, bifidâ, involucellis ovatis, foliis lanceolatis, ramis ſterilibus. Lin. Sp. Plant. 462. *Euphorbia with a multifid umbel, which is ſubtrifid and bifid, the ſmall involucrums oval, ſpear-ſhaped leaves, and ſteril branches.* Tithymalus paluſtris fruticoſus. C. B. P. 292. *Shrubby Marſh Spurge.*

23. Euphorbia (*Orientalis*) umbellâ quinquefidâ, quadrifidâ, dichotomâ, involucellis ſubrotundis acutis, foliis lanceolatis. Lin. Sp. Plant. 460. *Euphorbia with a quinquefid and quadrifid forked umbel, a pointed roundiſh involucrum, and ſpear-ſhaped leaves.* Tithymalus Orientalis, ſalicis folio, caule purpureo, flore magno. Tourn. Cor. 2. *Eaſtern Spurge with a Willow leaf, a purple ſtalk, and large flower.*

24. Euphorbia (*Characias*) umbellâ quinquefidâ, trifidâ dichotomâ, involucellis ovatis, foliis lanceolatis, capſulis lanatis. Lin. Sp. Plant. 460. *Euphorbia with a quinquefid trifid umbel, dividing by pairs, an oval involucrum, ſpear-ſhaped leaves and woolly capſules.* Tithymalus arboreus, caule corallino, folio Hyperici, pericarpio barbato. Boerh. Ind. alt. 1. p. 256. *Tree Spurge with a red ſtalk, a St. John's Wort leaf, and bearded capſule.*

25. Euphorbia (*Hiberna*) umbellâ ſextifidâ, dichotomâ, involucellis ovalibus, foliis integerrimis, ramis nullis capſulis verrucoſis. Lin. Sp. Plant. 462. *Euphorbia with a ſix-pointed forked umbel, oval involucrums, entire leaves, no branches, and warted capſules.* Tithymalus Hibernicus Machingboy dictus. Mer. Pin. *Iriſh Spurge, called Machingboy.*

26. Euphorbia (*Apios*) umbellâ quinquefidâ, bifidâ, involucellis obcordatis. Lin. Sp. Plant. 457. *Euphorbia with a quinquefid bifid umbel, and heart-ſhaped involucrums.* Tithymalus tuberosâ pyriformi radice. C. B. P. 292. *Spurge with a tuberous Pear-ſhaped root.*

27. Euphorbia (*Aleppica*) umbellâ quinquefidâ, dichotomâ, involucellis ovato-lanceolatis mucronatis, foliis inferioribus ſetaceis. Lin. Sp. Plant. 458. *Euphorbia with a quinquefid forked umbel, oval ſpear-ſhaped involucrums which are pointed, and the lower leaves briſtly.* Tithymalus Cypariſſius. Alp. Exot. 65. *Cypreſs Spurge.*

28. Euphorbia (*Cretica*) umbellâ multifidâ, bifidâ, involucellis orbiculatis, foliis lineari-lanceolatis villoſis. *Euphorbia with a multifid bifid umbel, orbicular involucrums, and narrow, ſpear-ſhaped, hairy leaves.* Tithymalus Creticus characias, anguſtifolius, villoſus & incanus. Tourn. Cor. 1. *Cretan Wood Spurge, with narrow, hairy, and hoary leaves.*

29. Euphorbia (*Sylvatica*) umbellâ multifidâ, dichotomâ, involucellis perfoliatis, ſubcordatis, foliis lanceolatis integerrimis. Lin. Sp. Plant. 463. *Euphorbia with a multifid forked umbel, heart-ſhaped perfoliate involucrums, and entire ſpear-ſhaped leaves.* Tithymalus ſylvaticus lunato flore. C. B. P. 290. *Wood-Spurge with a moon-ſhaped flower.*

30. Euphorbia (*Heterophylla*) inermis foliis ſerratis petiolatis difformibus ovatis lanceolatis panduriformibus. Lin. Sp. Plant. 453. *Euphorbia without ſpines, having ſawed leaves with foot-ſtalks which are deformed, oval, ſpear-ſhaped, and like a fiddle.* Tithymalus Curaſſavicus, ſalicis & atriplicis foliis variis, caulibus viridantibus. Pluk. Alm. 396. *Spurge from Curaſſao, with variable leaves like Willow and Orach, and a green ſtalk.*

31. Euphorbia (*Hypericifolia*) dichotomâ, foliis ſerratis ovali-oblongis glabris, corymbis terminalibus, ramis divaricatis. Lin. Sp. Plant. 454. *Forked Euphorbia with oblong, oval, ſmooth, ſawed leaves, and divaricated branches terminated by umbels.* Tithymalus erectus acris, parietariæ foliis glabris, floribus ad caulim nodos conglomeratis. Sloan. Cat. Jam. 82. *Upright acrid Spurge, with ſmooth Pellitory leaves, and flowers growing in cluſters from the joints of the ſtalk.*

32. Euphorbia (*Ocymoides*) inermis, herbacea, ramoſa, foliis, ſubcordatis integerrimis petiolatis floribus ſolitariis. Lin. Sp. Plant. 453. *Branching herbaceous Euphorbia without ſpines, having entire heart-ſhaped leaves with foot-ſtalks, and ſingle flowers.* Tithymalus Americanus, erectus, annuus, ramoſiſſimus ocymi caryophyllati foliis. Houſt. MSS. *Upright, annual, branching Spurge of America, with leaves like ſmall Baſil.*

The firſt ſort has been generally taken for the true Euphorbium of the ancients, and as ſuch hath been directed for medicinal uſe; but it is from the ſecond ſort, that the drug now imported under that title in England is taken. Dr. Linnæus ſuppoſes the fourth to be the ſort which ſhould be uſed, though as they are all nearly of the ſame quality, it may be indifferent which of them that drug is taken from, which is the inſpiſſated juice of the plant.

The firſt ſort hath a triangular, compreſſed, ſucculent ſtalk, which is jointed, and riſes to the height of eight or ten feet, ſending out many irregular twiſting branches, which are for the moſt part three-cornered, but have ſometimes only two, and at others four angles; they are compreſſed, ſucculent, and ſpread out on every ſide the ſtalk; theſe have at the extremity of the branches a few ſhort roundiſh leaves, which ſoon fall off; and near theſe come out now and then a few flowers, which have five thick whitiſh petals, with a large three-cornered germen in the center; theſe ſoon drop off without having any ſeeds. It grows naturally in India, from whence the plants were brought to the gardens in Holland, and have ſince been communicated to moſt of the curious gardens in Europe.

The ſecond ſort grows naturally in the Canary Iſlands, from whence I have been credibly informed, the Euphorbium which is imported in England, is now brought, and is the inſpiſſated juice of this plant. In its native country this grows to the height of twenty feet or more, but in England it is rarely ſeen more than ſix or ſeven; nor is it of any advantage to have them ſo tall here, becauſe they ſend out many branches which are large and ſucculent, ſo render the plants too heavy to be eaſily removed. This hath a very thick, green, ſucculent ſtalk, which has four or five large angles or corners, cloſely armed with black crooked ſpines, which come out by pairs at every indenture: the ſtalks ſend out from every ſide large ſucculent branches of the ſame form, which extend to the diſtance of two or three feet, then turn their ends upwards, ſo that when the plants are well grown, they have ſome reſemblance to a branched chandelier; theſe have no leaves, but are cloſely armed with black ſpines like the ſtalks; at the end of the branches come out the flowers, which are ſhaped like thoſe of the firſt ſort.

The third ſort hath a naked three-cornered ſtalk which is compreſſed, ſending out a great number of branches which grow erect, and join up to the main ſtalk; theſe are generally three-cornered, but ſome vary to four; they are jointed and armed with ſhort crooked ſpines, but have no leaves, nor do the plants produce flowers here. This grows naturally in India.

The fourth ſort puts out many ſtalks juſt above the ſurface of the ground, which are thick, ſucculent, and roundiſh, having eight or ten angles while they are young, but as they grow old they loſe their angles and become round; the branches grow diſtorted and irregular, firſt horizontal, and afterward turn upward; they are armed with ſmall crooked ſpines on their angles, and on the upper part of the branches come out the flowers, which are ſmall, and of a greeniſh white, ſhaped like thoſe of the ſecond ſort. This grows naturally in India.

The fifth ſort grows naturally in India; this riſes with a ſtrong upright ſtalk five or ſix feet high, which hath irregular angles, and protuberances which are oblique to the angles; the lower part of the ſtalk is naked, the upper part is branching, and the branches are armed with crooked ſpines; at every protuberance, and at the top, they are garniſhed with oblong leaves of a lucid green, which are very ſmooth, entire, and rounded at their ends; theſe fall off, and the plants remain naked for ſome months, and then the flowers come out, which ſit cloſe to the branches, and are of a greeniſh white colour; the leaves come out in the autumn, and fall off in the ſpring.

The ſixth ſort riſes with a roundiſh, upright, ſucculent ſtalk about three feet high, putting out ſeveral branches on the ſide of the ſame form; theſe have ſeven angles or furrows, which are armed with long, ſingle, black thorns; at the end of which come out ſmall flowers, of the ſame form with thoſe of the other ſorts, and are ſometimes ſucceeded by ſmall fruit.

The ſeventh ſort hath thick, roundiſh, ſucculent ſtalks, which are ſcaly; theſe ſend out many branches from their ſides of the ſame form, which are twiſted, and run one over another, ſo as to appear like a parcel of ſerpents coming out from the ſtalks, from whence it had the appellation of Meduſa's Head. The ends of the branches are garniſhed with narrow, thick, ſucculent leaves, which drop off, and round the upper part of the branches the flowers come out; theſe are white, and of the ſame form with thoſe of the other ſpecies, but larger, and are frequently ſucceeded by round ſmooth capſules with three cells, each including a ſingle roundiſh ſeed.

The eighth ſort hath roundiſh ſtalks, which ſwell out like a belly in the middle, and have knobbed angles, between which come out long ſpines which are ſtrait; theſe ſtalks riſe two feet high, and put out a few branches on their ſide of the ſame form; the flowers are produced at the end of the branches, ſitting cloſe upon the angles; they are ſmall, of a yellowiſh green colour, and ſhaped like thoſe of the other ſpecies.

The ninth ſort hath ſtalks and branches very like thoſe of the fourth, but much ſlenderer; the ſpines of this are ſingle, and thoſe of the other double; and the ends of the branches are cloſely garniſhed with flowers on every angle, in which it differs from the fourth ſort.

The tenth ſort hath a thick ſhort ſtalk, which ſeldom riſes more than eight or ten inches high, from which come out a great number of trailing branches which are ſlender, and grow about a foot in length; theſe intermix with each other like thoſe of the ſeventh ſort, but they are much ſmaller, and do not grow near ſo long, but have the ſame appearance, from whence it is called Little Meduſa's Head: the ends of theſe branches are beſet with narrow leaves, between which the flowers come out, which are white, and ſhaped like thoſe of the other ſpecies.

The eleventh ſort riſes with a taper ſtalk ſix or ſeven inches high, ſending out from the top a few taper branches, which ſpread out on every ſide; theſe are not ſcaly, like thoſe of the laſt ſort, but taper, and garniſhed at their ends with ſeveral ſmall narrow leaves which drop off. This ſort hath not yet flowered here, having been but a ſhort time in England.

The twelfth ſort hath a ſhort thick ſtalk, which never riſes three inches high, ſo that the branches ſpread on the ſurface of the ground; theſe ſeldom grow more than ſix inches long, and their ſcales ſwell into a ſort of protuberances which are ſquare; they have no leaves, and very rarely produce flowers in England, but has been long an inhabitant in the gardens.

The thirteenth ſort is very like the ſeventh, but the ſtalks never riſe more than a foot or fifteen inches high, ſo that the branches ſpread out near the ground; theſe are alſo much ſhorter than thoſe of the ſeventh, but have the ſame appearance, and are garniſhed with narrow leaves at their end, which fall off as the branches are extended in length: this produces a great number of ſmall white flowers at the end of the branches, which are ſhaped like thoſe of the other ſpecies, and are frequently ſucceeded by round ſmooth capſules with three cells, including one or two roundiſh ſeeds which ripen here.

Theſe ſorts have been by moſt of the modern botaniſts ranged under the title of Euphorbium, and have been diſtinguiſhed from the Tithymali, more from the ſtructure and outward appearance of the plants, than any real difference in their characters, as hath been before obſerved; but as the number of ſpecies of thoſe commonly called Spurge was very great, ſo many of the writers were willing to ſeparate the Euphorbia from that genus, to leſſen the number of ſpecies.

Theſe plants are preſerved in many curious gardens, more for the oddneſs of their ſtructure, than any real beauty; but being ſo extremely different in their form, from almoſt any plants of European production, many curious perſons have been induced to preſerve the ſeveral ſorts in their gardens.

They are all of them full of a milky acrid juice, which flows out on their being wounded in any part; this juice will bliſter the fleſh, if it happen to lie upon any tender part for a ſhort time, and will burn linen almoſt as bad as aqua fortis, therefore the plants ſhould be handled with great caution; nor ſhould the ends of their branches be ever bruiſed or injured; for if they are, it frequently occaſions their rotting down to the next joint, and ſometimes will deſtroy the whole plant, if thoſe injured branches are not cut off in time; ſo that whenever the branches appear to have been injured, the ſooner they are cut from the plants, the leſs danger there will be of their ſuffering from it; nor ſhould any of the branches be cut between the joints, for the ſame reaſon.

Moſt of theſe plants were firſt brought to Europe by the Dutch, who have been very curious to introduce great numbers of plants from India, and alſo from the Cape of Good Hope: from the latter there hath been a very great variety of curious plants of late years brought to Europe, many of which produce very elegant flowers, and are the greateſt ornaments of the conſervatory in the winter and ſpring ſeaſons. Theſe have been brought over in ſeeds, but the different kinds of Euphorbia came over moſt of them in plants or cuttings; for theſe may be eaſily tranſported to any diſtance, if either of them are put up in boxes, with any ſoft dry package, to prevent their being bruiſed, or their ſpines from wounding each other, and kept from moiſture and cold; with this care they may be kept ſix months out of the ground, and if carefully planted will take root, and thrive as well as if they had been newly taken from the old plants, or out of the ground but a ſhort time; which is a much more expeditious method of obtaining the plants than from ſeeds, when they can be procured.

The greateſt part of theſe ſucculent plants grow naturally upon barren rocky places, or in dry ſandy ſoils, where few other plants will thrive; therefore they ſhould never be planted in rich or loamy earth here, nor ſuffered to receive much wet, which will cauſe them to rot. The beſt mixture of earth for theſe plants is about a fourth part of ſcreened limerubbiſh, a fourth part of ſea-ſand, and half of light freſh earth from a common; theſe ſhould be mixed well together, and frequently turned over before it it uſed, that the parts may be incorporated, and the compoſt ſweetened by being expoſed to the air. If this mixture is prepared a year before it is wanted, it will be the better, that it may have the benefit of the winter's froſt and the ſummer's heat to mellow it; and the oftener it is turned over, and the ſmaller the heaps are in which it is laid, the air will penetrate it better, and render it more fit for uſe.

Theſe ſorts are eaſily propagated by cuttings, which ſhould be taken from the old plants in June; theſe muſt be cut at a joint, otherwiſe they will rot. When theſe cuttings are taken off, the milky juice of the old plants will flow out in plenty; therefore there ſhould be ſome dry earth or ſand applied upon the wounded part, which will harden and ſtop the ſap; and the wounded part of the cuttings ſhould alſo be rubbed in ſand, or dry earth, for the ſame purpoſe; then the cuttings ſhould be laid in a dry part of the ſtove, for ten days or a fortnight; and ſome of thoſe whoſe branches are large and very ſucculent, may lie three weeks or more before they are planted, that their wounds may be healed and hardened, otherwiſe they will rot. When the cuttings are planted, they ſhould be each put into a ſmall halfpenny pot, laying ſtones or rubbiſh in the bottom, and filling the pots with the mixture before directed; then plunge the pots into a moderate hot-bed, and if the weather is very hot, the glaſſes of the hot-bed ſhould be ſhaded in the middle of the day, and the cuttings ſhould be gently watered once or twice a week, according as the earth may dry: in about ſix weeks or two months the cuttings will have put out roots, ſo if the bed is not very warm, the plants may continue there, provided they have free air admitted to them every day, otherwiſe it will be better to remove them into the ſtove, where they may be hardened before the winter; for if they are too much drawn in ſummer, they are very apt to decay in winter, unleſs they are very carefully managed. During the ſummer ſeaſon, theſe plants ſhould be gently watered two or three times a week, according to the warmth of the ſeaſon; but in winter they muſt not be watered oftener than once a week, and it ſhould be given more ſparingly at that ſeaſon, eſpecially if the ſtove is not warm: the firſt ſort will require more warmth in the winter than any of the other, as alſo leſs water at that ſeaſon. This, if well managed, will grow ſeven or eight feet high; but the plants muſt conſtantly remain in the ſtove, giving them a large ſhare of air in warm weather, and in winter the ſtove ſhould be kept in a temperate degree of warmth.

The ſixth ſort is at preſent the moſt rare in England: the plants of this ſort, which have been procured from Holland, have been moſt of them deſtroyed by placing them in ſtoves, where, by the heat, they have in one day turned black, and rotted immediately after. This ſort will thrive well if placed in a dry airy glaſs-caſe with Ficoides, and other ſucculent plants in the winter, where they may have free air in mild weather, and be protected from froſt; in ſummer the plants of this ſort may be expoſed in the open air, in a warm ſituation, but ſhould be ſcreened from much wet: with this treatment, the plants will thrive much better than when they are more tenderly nurſed.

The ſeventh, eighth, tenth, eleventh, twelfth, and thirteenth ſorts, are alſo pretty hardy, ſo will live in a good glaſs-caſe in winter without fire, provided the froſt is kept entirely out, and in ſummer they may be placed abroad in a warm ſituation: as theſe are very ſucculent plants, they ſhould not have too much wet; therefore, if the ſummer ſhould prove very moiſt, it will be very proper to place theſe plants under ſome ſhelter, where they may enjoy the free air, and be ſcreened from the rain, otherwiſe by receiving too much wet in ſummer they will rot in winter.

The ſeventh ſort will require to be ſupported, otherwiſe the weight of the branches will draw them upon the pots; and, by training of the ſtems up to ſtakes, they will grow four or five feet high, and a great number of ſide branches will be produced; theſe, being very ſucculent and heavy, are very apt to draw down the ſtem if it hath not ſupport.

The following ſorts have been, by all the writers on botany, placed under the title of Tithymalus; but the fourteenth and fifteenth ſorts ſhould, according to their own diſtinction, have been placed in the genus of Euphorbium, becauſe they are as deſtitute of leaves as moſt of the ſpecies which they have there placed.

The fourteenth ſort riſes with a taper ſucculent ſtalk to the height of eighteen or twenty feet, ſending out many branches of the ſame form, which ſubdivide into many ſmaller; theſe are jointed but at a great diſtance: they are ſmooth, and of a deep green colour, having a few ſmall leaves at their extremities, which ſoon fall off. As the plants grow older, their ſtalks become ſtronger and leſs ſucculent, eſpecially toward the bottom, where they turn to a brown colour, and become a little woody. The branches grow diffuſed and intermix with each other, ſo form a ſort of buſh toward the top, but this doth not produce flowers here.

The fifteenth ſort ſends out a great number of ſlender taper ſtalks of a dark green colour, which are ſmooth, and twiſt about each other, or any neighbouring ſupport, whereby they will riſe to the height of ten or twelve feet, putting out ſmaller branches upward, which alſo twine and intermix with the other ſtalks; they are naked, having no leaves, nor do the plants flower in England. Theſe grow in India.

The ſixteenth ſort ſends out many taper ſucculent ſtalks from the root, which riſe about four feet high; they are ſlender and weak, ſo require ſupport to prevent their falling to the ground; theſe have a light green bark, and their lower parts are naked, but their upper parts are garniſhed with oblong leaves, which are ſmooth, entire, and placed alternate on every ſide the ſtalks: the flowers are produced in ſmall cluſters at the end of the branches, they are of a yellowiſh green colour, and are ſometimes ſucceeded by ſmooth round fruit, but the ſeeds rarely ripen in England. This ſort grows naturally on the African ſhore in the Mediterranean.

The ſeventeenth ſort grows naturally in ſome of the iſlands of the Weſt-Indies, and alſo upon the continent there. I received ſpecimens of this ſort from the iſland of Tobago, and alſo from Carthagena, where the plants were growing in plenty; the Dutch gardens were furniſhed with it from Curaſſao, where it alſo grows naturally. This hath an upright ſtalk, which riſes to the height of ſix or ſeven feet, covered with a light brown bark, and divides upward into many branches; theſe are garniſhed with roundiſh leaves, which are indented at their ends, and have foot-ſtalks: they are ſmooth and of a beautiful green, but fall away in winter, ſo that in the ſpring they are almoſt naked; the flowers come out from the end of the branches, they are yellow and ſmall, ſoon falling away without having any fruit ſucceed them here.

Theſe ſorts are propagated by cuttings, in the ſame manner as the Euphorbiums, and the plants muſt be treated in the ſame way, as hath been directed for them.

The fourteenth, fifteenth, and ſeventeenth ſorts, are tender, ſo require a ſtove; theſe muſt have the ſame treatment as the tender kinds of Euphorbiums, but the ſixteenth ſort will live in a common green-houſe in winter, and may be expoſed abroad in the ſummer.

The eighteenth ſort ſtands in the liſt of medicinal plants, but is rarely uſed in England at preſent; this is a biennial plant, which periſhes after the ſeeds are ripe. It grows naturally in Italy and the ſouth of France, and where it is allowed to ſcatter its ſeeds in a garden, becomes a weed here. This riſes with an upright ſucculent ſtalk from three to four feet high, garniſhed with oblong ſmooth leaves which are placed oppoſite, and ſit cloſe to the ſtalks; the upper part of the ſtalk divides by pairs into ſmaller forked branches, and from the fork between theſe diviſions come out the umbels of flowers, each fork having one; that which is ſituated in the firſt diviſion being the largeſt, and thoſe in the upper the ſmalleſt. The flowers are of a greeniſh yellow colour; they appear in June and July, and the fruit follows ſoon after, which is divided into three lobes, and has three cells, each containing one roundiſh ſeed, which is caſt out at a diſtance by the elaſticity of the pods. This ſort will propagate itſelf faſt enough when it is once introduced into gardens, ſo requires no care but to keep it clean from weeds.

The nineteenth ſort grows naturally in the ſouth of France, in Spain, and Italy. This ſends out many trailing branches from the root, which grow about a foot long, lying upon the ground, which are cloſely garniſhed with thick ſucculent leaves; theſe are flat, ſhort, and pointed; they ſpread open on every ſide the branches, and are placed alternate, ſitting cloſe to the ſtalks: the flowers are produced in large umbels at the end of the branches; the involucrum of the principal umbel is compoſed of ſeveral oval-pointed leaves, but thoſe of the ſmall umbels have only two heart-ſhaped concave leaves, whoſe borders are rough; the flowers are yellow, and are ſucceeded by three ſeeds, incloſed in a roundiſh capſule with three cells. This plant will continue two or three years upon a dry warm ſoil, and will ripen ſeeds annually; which, if permitted to ſcatter, the plants will come up, and require no other care but to keep them clean from weeds.

The twentieth ſort grows naturally in Crete, and in ſeveral iſlands of the Archipelago; this riſes with an upright branching ſtem to the height of four feet; the leaves of this are oblong and pointed, and are placed alternate on the branches; the flowers come out in umbels from the fork between the branches; they are ſmall and yellow, and are rarely ſucceeded by ſeeds in England. It is eaſily propagated by cuttings during any of the ſummer months, and requires a little protection from the froſt in winter.

The twenty-firſt ſort grows naturally in the woods in many parts of England; it riſes with a ſhrubby ſtalk three feet high; the flowers are produced in umbels ſitting cloſe to the ſtalks, ſo form a long ſpike; the empalements are of a greeniſh yellow, and the petals black, ſo they make an odd appearance. It flowers in May, and the ſeeds ripen in July. If the ſeeds of this are ſown under trees in the autumn, the plants will riſe the following ſpring, and require no culture.

The twenty-ſecond ſort ſtands in the liſt of medicinal plants by the title of Eſula major, but at preſent is ſeldom uſed: this grows naturally in France and Germany upon marſhy places, where it riſes three or four feet high. It hath a perennial root, by which it may be propagated better than by ſeeds, which ſeldom grow, unleſs they are ſown ſoon after they are ripe.

The twenty-third ſort was diſcovered in the Levant, by Dr. Tournefort, who ſent the ſeeds to the royal garden at Paris; this hath a perennial root, from which ariſe many ſucculent ſtalks three feet high, covered with a purple bark, and garniſhed with oblong ſmooth leaves, ſhaped like thoſe of Willow, of a dark green colour. The upper part of the ſtalks divide, and in the fork is ſituated an umbel of flowers of a greeniſh yellow colour, which are ſucceeded by round capſules with three cells, each containing a ſingle ſeed. It flowers in June, and the ſeeds are ripe in Auguſt; this may be propagated by parting the roots, or by ſowing the ſeeds in autumn. The plant is hardy, ſo will endure the greateſt cold of this country, if it is planted in a dry ſoil.

The twenty-fourth ſort grows naturally in Sicily, and on the borders of the Mediterranean Sea; this riſes with ſeveral ſhrubby ſtalks to the height of five or ſix feet, having a red bark, and are garniſhed with oblong, ſmooth, blunt leaves, which are placed alternate. The flowers grow in ſmall umbels from the diviſion of their branches; they are yellow, and are ſucceeded by roundiſh capſules, which are rough, having three cells like the other ſpecies. This is eaſily propagated by cuttings during any of the ſummer months, and requires protection from the froſt in winter.

The twenty-fifth ſort grows naturally in Ireland, from whence the roots have been brought to England; this hath thick fibrous roots, which ſend up ſeveral ſingle unbranched ſtalks about a foot high, garniſhed with oblong leaves, placed alternate on every ſide. The flowers are produced in ſmall umbels at the top of the ſtalks; they are yellow, and are ſucceeded by rough warted capſules with three cells; it flowers in June, and the ſeeds ripen in Auguſt. This may be propagated by the roots, which ſhould be planted in a ſhady ſituation and a moiſt ſoil.

This plant was almoſt the only phyſic uſed by the native inhabitants of Ireland formerly; but ſince the uſe of mercury has been known to them, the other has been generally neglected.

The twenty-ſixth ſort grows naturally in the Levant; this hath a knobbed Pear-ſhaped root, from which ariſe two or three ſtalks about a foot and a half high, garniſhed with oblong leaves, which are hairy, placed alternate on every ſide the ſtalk. The flowers are produced in ſmall umbels from the diviſions of the ſtalk; they are ſmall, of a greeniſh yellow colour, and are ſeldom ſucceeded by ſeeds here; it may be propagated by offſets, ſent out from the main root; theſe may be taken off in autumn, and planted in a ſhady ſituation, where they will thrive better than in the full ſun.

The twenty-ſeventh ſort grows naturally at Aleppo, and in other parts of the Levant; this hath a perennial creeping root, by which it multiplies very faſt where it is once eſtabliſhed. The ſtalks of this riſe a foot and a half high; the lower leaves are narrow, ſtiff, and briſtly; but thoſe on the upper part of the ſtalk are ſhaped like the narrow-leaved Myrtle. The flowers are produced in large umbels from the diviſions of the ſtalk; they are yellow, and appear in June, but are rarely ſucceeded by ſeeds in this country. The roots of this ſhould be confined in pots; for when they are planted in the full ground, they creep about to a great diſtance.

The twenty-eighth ſort grows naturally in many parts of the Levant, and alſo in Spain and Portugal. The ſeeds of this were brought me from Scanderoon, by the late Mr. Robert Millar, who found the plants growing plentifully there; and he aſſured me, that he ſaw the inhabitants wounding of theſe plants, and collecting their milky juice, which they mixed up with the Scammony to ſend abroad.

The ſeeds of this plant were ſince ſent me from Portugal, by Robert More, Eſq; who found the plants growing there naturally, but this plant had been many years before an inhabitant in the Engliſh gardens; this riſes with a purple ſhrubby ſtalk near three feet high, which is garniſhed with narrow, ſpear-ſhaped, hairy leaves, ſet cloſely on the ſtalk alternately on every ſide; the upper part of the ſtalk is terminated by umbels of flowers, which form a ſort of ſpike. The greater umbels are multifid, but the ſmall ones are bifid. The involucrums of the flowers are yellow, and the petals of the flowers black; theſe appear in May, and are ſucceeded by ſeeds which ripen in July: the young plants which have been lately raiſed from ſeeds, are generally very fruitful, but the old ones, and thoſe raiſed by cuttings are barren; this may be propagated by ſeeds, or from cuttings, and will live abroad if planted in a dry rubbiſhy ſoil and a warm ſituation, otherwiſe they are frequently killed by ſevere froſt.

The twenty-ninth ſort grows naturally in the ſouth of France, in Spain, and Italy; this is a biennial plant, from whoſe root ariſe two or three ſtalks, which grow two or three feet high, garniſhed with ſpear-ſhaped leaves, which are entire. The umbels of flowers ariſe from the diviſion of the branches; the involucrums are heart-ſhaped, and ſurround the pedicle with their baſe. The flowers are yellow, and appear in June. The ſeeds ripen in Auguſt; which, if permitted to ſcatter, the plants will come up, and require no other care but to keep them clean from weeds; this muſt have a ſhady ſituation.

The thirtieth ſort grows naturally at La Vera Cruz, from whence the late Dr. Houſtoun ſent me the ſeeds; this is an annual plant, which riſes from two to three feet high. The leaves of theſe are ſometimes narrow and entire, at other times oval, and divided in the middle, almoſt to the midrib, in ſhape of a fiddle; they alſo vary in their colour, ſome being inclinable to purple, others of a light green; they are ſawed on their edges, and ſtand upon ſhort foot-ſtalks. The flowers are produced in ſmall umbels at the end of the branches; they are of a greeniſh white, and are ſucceeded by ſmall round capſules with three cells.

The thirty-firſt ſort grows naturally in moſt of the iſlands in the Weſt-Indies; this is an annual plant, which riſes with a branching ſtalk about two feet high, garniſhed with oblong, oval, ſmooth leaves, which are ſawed on the edges. The flowers grow in ſmall umbels at the foot-ſtalks of the leaves, gathered into cloſe bunches; theſe are white, and are ſucceeded by ſmall round capſules, incloſing three ſeeds.

The ſeeds of the thirty-ſecond ſort were ſent me from La Vera Cruz, by the late Dr. Houſtoun; this is an annual plant, which riſes with an upright ſtalk about a foot high, dividing into a great number of branches, which ſpread very wide on every ſide, garniſhed with roundiſh, heart-ſhaped leaves, which are entire, ſtanding upon pretty long foot-ſtalks. The flowers come out ſingly from the diviſions of the ſtalk; they are ſmall, and of an herbaceous colour, and are ſucceeded by ſmall round capſules, containing three ſeeds.

The laſt three ſorts are annual; the ſeeds of theſe muſt be ſown upon a hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be each planted in a ſmall pot filled with light earth, and plunged into the hot-bed again, and muſt afterward be treated in the ſame manner as other tender annual plants from warm countries.

EUPHRASIA. Eyebright.

This is a medicinal plant, which grows naturally in the fields and commons in moſt parts of England, always among graſs, heath, furz, or ſome other cover, and will not grow when theſe are cleared from about it; nor will the ſeeds grow when they are ſown in a garden; for which reaſon I ſhall not trouble the reader with a deſcription, or any farther account of it, than that the herb-women ſupply the markets with it in plenty from the fields.

EXCORTICATION [excorticatio, *Lat.*] a pulling or peeling off the outward bark of trees.

EXOTICS [exotica, *Lat.*] Exotic plants are ſuch as are natives of foreign countries.

F.

FABA. Tourn. Inſt. R. H. 391. tab. 212. Vicia. Lin. Gen. Plant. 782. The Bean; in French, *Féve*.

The CHARACTERS are,

The flower hath a tubulous empalement of one leaf, which is cut into five ſegments at the brim; the three lower ſegments being long, and the two upper are very ſhort. The flower is of the butterfly kind. The ſtandard is large, oval, and indented at the end; the two ſides turn backward, after ſome time; it hath two oblong erect wings, which incloſe the keel, being much longer. The keel is ſhort, ſwelling, and cloſely covers the parts of generation; theſe are joined in one column, almoſt to the top where they are divided; the nine ſtamina are in three parts, and one ſtands ſeparate; theſe are terminated by roundiſh reclined ſummits. At the bottom is ſituated an oblong compreſſed germen, ſupporting a ſhort angular ſtyle, crowned by an obtuſe ſtigma, which is bearded on the two ſides. The germen afterward becomes a long, compreſſed, leathery pod, having one cell, filled with compreſſed kidney-ſhaped ſeeds.

Tournefort ranges this genus of plants in the ſecond ſection of his tenth claſs, which includes the herbs with a butterfly flower, whoſe pointal turns to a long pod with one cell. This is in the third ſection of Linnæus's ſeventeenth claſs, in which he places thoſe plants whoſe flowers have ten ſtamina, joined in two bodies; and he joins it to his genus of Vicia, ſo he makes only a ſpecific difference between them; but as the Bean hath a compreſſed leathery pod and kidney-ſhaped ſeeds, and the Vetch a ſwelling pod with round ſeeds, they ſhould be ſeparated.

There are ſeveral varieties of the Garden Bean, which are known and diſtinguiſhed by the gardeners, but do not eſſentially differ from each other; ſo I ſhall not enumerate them as diſtinct ſpecies, nor join theſe to the Horſe Bean, as ſome have done, who have ſuppoſed them to be but one ſpecies; for, from having cultivated them more than forty years, without finding the Garden Bean degenerate to the Horſe Bean, or the latter improving to the former, I conclude they are diſtinct ſpecies.

There is a great variety of the Garden Beans, now cultivated in the kitchen-gardens in England, which differ in ſize and ſhape; ſome of them producing their pods much earlier in the year than others, for which they are greatly eſteemed by the gardeners, whoſe profit ariſes from their early crops of moſt eſculent plants; therefore they are very careful to improve all thoſe varieties which have a tendency to be fit for the markets firſt; but as many ſorts of ſeeds, when cultivated long in the ſame land, are apt to degenerate, ſo new ſeeds ſhould be annually procured, either from abroad, or ſome diſtant ſituation, where the ſoil is of a different nature, by which change many of the varieties may be continued in perfection.

I ſhall begin with the Garden Bean, called by the botaniſts, Faba major to diſtinguiſh it from the Horſe Bean, which they have titled Faba minor ſeu Equina; and I ſhall only mention the names of each, by which they are known among the gardeners, placing them according to their time of ripening for the table.

The Mazagan Bean is the firſt and beſt ſort of early Beans at preſent known; theſe are brought from a ſettlement of the Portugueſe on the coaſt of Africa, juſt without the Streights of Gibraltar; the ſeeds of this ſort are ſmaller than thoſe of the Horſe Bean; and as the Portugueſe are but ſlovenly gardeners, there is commonly a great number of bad ſeeds among them. If this ſort is ſown in October, under a warm hedge, pale, or wall, and carefully earthed up when the plants are advanced, they will be fit for the table by the middle of May. The ſtems of this ſort are very ſlender, therefore, if they are ſupported by ſtrings cloſe to the hedge, or pale, it will preſerve them from the morning froſts, which are ſometimes ſevere in the ſpring, and retard their growth; ſo by keeping them cloſe to the fence it will cauſe them to come forwarder than if this is neglected; theſe Beans bear plentifully, but they ripen nearly together, ſo that there are never more than two gatherings from the ſame plants; if the ſeeds of this ſort are ſaved two years in England, the Beans will become much larger, and not ripen ſo ſoon, which is called a degeneracy.

The next ſort is the early Portugal Bean, which appears to be the Mazagan ſort ſaved in Portugal, for it is very like thoſe which are the firſt year ſaved in England; this is the moſt common ſort uſed by the gardeners for their firſt crop, but they are not near ſo well taſted as the Mazagan; therefore when the Mazagan Bean can be procured, no perſon would plant the other.

The next is the ſmall Spaniſh Bean; this will come in ſoon after the Portugal ſort, and is rather a ſweeter Bean, therefore ſhould be preferred to it.

Then comes the broad Spaniſh, which is a little later than the other, but comes in before the common ſorts, and is a good bearer, therefore is frequently planted.

The Sandwich Bean comes ſoon after the Spaniſh, and is almoſt as large as the Windſor Bean; but, being hardier, is commonly ſown a month ſooner; this is a plentiful bearer, but not very delicate for the table.

The Toker Bean, as it is generally called, comes about the ſame time with the Sandwich, and is a great bearer; therefore is now much planted, though it is a coarſe Bean.

The white and black Bloſſom Beans are alſo by ſome perſons much eſteemed; the Beans of the former are, when boiled, almoſt as green as Peas; and being a tolerable ſweet Bean, renders it more valuable; theſe ſorts are very apt to degenerate, if their ſeeds are not ſaved with great care.

The Windſor Bean is allowed to be the beſt of all the ſorts for the table; when theſe are planted on a good ſoil, and are allowed ſufficient room, their ſeeds will be very large, and in great plenty; and when they are gathered young, are the ſweeteſt and beſt taſted of all the ſorts; but theſe ſhould be carefully ſaved, by pulling out ſuch of the plants as are not perfectly right, and afterward by ſorting out all the good from the bad Beans.

This ſort of Bean is ſeldom planted before Chriſtmas, becauſe it will not bear the froſt ſo well as many of the other ſorts; ſo it is generally planted for the great crop, to come in June and July.

All the early Beans are generally planted on warm borders under walls, pales, and hedges; and thoſe which are deſigned to come firſt, are uſually planted in a ſingle row pretty cloſe to the fence: and here I cannot help taking notice of a very bad cuſtom, which too generally prevails in gentlemens kitchen-gardens, which is that of planting Beans cloſe to the garden-walls, on the beſt aſpects, immediately before the fruit-trees, which is certainly a greater prejudice to the trees, than the value of the Beans, or any other early crop; therefore this practice ſhould be everywhere diſcouraged; for it is much better to run ſome low Reed hedges acroſs the quarters of the kitchen-garden, where early Beans and Peas may be planted, in which places they may with more conveniency be covered in ſevere froſt; and to theſe hedges they may both be cloſely faſtened, as they advance in their growth; which, if practiſed againſt the walls where good fruit-trees are planted, will greatly prejudice the trees, by overſhadowing them, and the growth of theſe legumes will draw off the nouriſhment from the roots of the trees, whereby they will be greatly weakened.

But to return to the culture of the Beans. Thoſe which are planted early in October, will come up by the beginning of November; and as ſoon as they are an inch above ground, the earth ſhould be carefully drawn up with a hoe to their ſtems; and this muſt be two or three times repeated, as the Beans advance in height; which will protect their ſtems from the froſt, and encourage their ſtrength. If the winter ſhould prove ſevere, it will be very proper to cover the Beans with Peas-haulm, Fern, or ſome other light covering, which will ſecure them from the injury of froſt; but this covering muſt be conſtantly taken off in mild weather, otherwiſe they will draw up tall and weak, and come to little; and if the ſurface of the border is covered with tanners bark, it will prevent the froſt penetrating the ground to the roots of both, and be of great ſervice to protect them from the injury which they might otherwiſe receive.

In the ſpring, when the Beans are advanced to be a foot high, they ſhould be faſtened up to the hedge with packthread or a ſmall line, ſo as to draw them as cloſe as poſſible; which will ſecure them from being injured by the morning froſts, which are often ſo ſevere in March and April, as to lay thoſe Beans flat on the ground, which are not thus guarded; at this time all ſuckers which come out from the roots ſhould be very carefully taken off; for theſe will retard the growth of the Beans, and prevent their coming early; and when the bloſſoms begin to open toward the bottom of the ſtalks, the top of the ſtems ſhould be pinched off, which will cauſe thoſe firſt pods to ſtand, and thereby bring them forward. If theſe rules are obſerved, and the ground kept clean from weeds, or other plants, there will be little danger of their failing.

But leſt this firſt crop ſhould be deſtroyed by froſt, it will be abſolutely neceſſary to plant more about three weeks after the firſt, and ſo to repeat planting more every three weeks, or a month, till February; but thoſe which are planted toward the end of November, or the beginning of December, may be planted on ſloping banks, at a ſmall diſtance from the hedges; for if the weather is mild, theſe will not appear above ground before Chriſtmas; therefore will not be in ſo much danger as the firſt and ſecond planting, eſpecially if the ſurface of the ground is covered with tan to keep the froſt out of the ground as is before directed; for the firſt planting will, by that time, be a conſiderable height: the ſame directions which are before given will be ſufficient for the management of theſe; but only it muſt be obſerved, that the larger Beans ſhould be planted at a greater diſtance than the ſmall ones; as alſo, that thoſe which are firſt planted muſt be put cloſer together, to allow for ſome miſcarrying; therefore, when a ſingle row is planted, the Beans may be put two inches aſunder, and thoſe of the third and fourth planting may be allowed three inches; and when they are planted in rows acroſs a bank, the rows ſhould be two feet and a half aſunder; but the Windſor Beans ſhould have a foot more ſpace between the rows, and the Beans in the rows ſhould be planted five or ſix inches aſunder. This diſtance may, by ſome perſons, be thought too great; but from many years experience, I can affirm, that the ſame ſpace of ground will produce a greater quantity of Beans when planted at this diſtance, than if double the quantity of ſeeds are put on it. In the management of theſe later crops of Beans, the principal care ſhould be to keep them clear from weeds, and any other plants which would draw away their nouriſhment; to keep earthing them up, and, when they are in bloſſom, to pinch off their tops; which, if ſuffered to grow, will draw the nouriſhment from the lower bloſſoms, which will prevent the pods from ſetting, and ſo only the upper parts of the ſtems will be fruitful; and another thing ſhould be obſerved in planting of the ſucceeding crops, which is, to make choice of moiſt ſtrong land for the later crops; for if they are planted on dry ground, they rarely produce a crop.

Theſe after-crops ſhould be planted at about a fortnight diſtance from each other, from the middle of February to the middle of May; after which time it is generally too late to plant, unleſs the land is very ſtrong and moiſt; for in warm dry light land all the late crops of Beans are generally attacked by the black inſects, which cover all the upper part of their ſtems, and ſoon cauſe them to decay.

Where the ſeeds of theſe Beans are deſigned to be ſaved, a ſufficient number of rows ſhould be ſet apart for that purpoſe, according to the quantity deſired; theſe ſhould be managed in the ſame way as thoſe which are deſigned for the table; but none of the Beans ſhould be gathered, though there are ſome covetous perſons, who will gather all the firſt ripe for the table, and are contented to ſave the after-crop for ſeed, but theſe are never ſo large and fair as the firſt; ſo that if theſe are for ſale, they will not bring near the price as the other; therefore, what is gained to the table is loſt in the value of the ſeed; but thoſe who are deſirous to preſerve the ſeveral varieties as pure as poſſible, ſhould never ſuffer two of the varieties to grow for ſeeds in the ſame place; for by their farina mixing with each other they will not continue ſo pure, but be apt to vary; and in order to keep the early kinds perfect, thoſe which come the earlieſt ſhould be ſaved for ſeeds; but this is what few people chuſe to do, becauſe they are then the moſt valuable.

When the ſeed is ripe, the ſtalks ſhould be pulled up, and ſet upright againſt a hedge to dry, obſerving to turn them every third day, that they may dry equally; then they may be threſhed out, and cleaned for uſe, or otherwiſe ſtacked up in a barn, till there is more leiſure for threſhing them out; and afterward the ſeed ſhould be drawn over to take out all thoſe that are not fair, preſerving the beſt for uſe or ſale.

It is a very good method to change the ſeeds of all ſorts of Beans, and not to ſow and ſave the ſeeds long in the ſame ground, for they do not ſucceed ſo well; therefore, if the land is ſtrong where they are to be planted, it will be the beſt way to procure the ſeeds from a lighter ground, and ſo vice verſa; and by this method the crops will be larger, and the Beans fairer, and not ſo liable to degenerate.

Having given directions for the culture of the Garden Beans, I ſhall next proceed to that of the Horſe Bean, which is cultivated in the fields: there are two or three varieties of theſe Beans, which differ in their ſize and colour; but that which is now in the greateſt eſteem, is called the Tick Bean; this doth not grow ſo high as the other, is a more plentiful bearer, and ſucceeds better on light land than the common Horſe Bean, ſo preferred to it.

The Horſe Bean delights in a ſtrong moiſt ſoil, and an open expoſure, for they never thrive well on dry warm land, or in ſmall incloſures, where they are very ſubject to blight, and are frequently attacked by a black inſect, which the farmers call the black dolphin; theſe inſects are often in ſuch quantities as to cover the ſtems of the Beans entirely, eſpecially all the upper part of them; and whenever this happens, the Beans ſeldom come to good; but in the open fields, where the ſoil is ſtrong, this rarely happens.

Theſe Beans are uſually ſown on land which is freſh broken up, becauſe they are of uſe to break and pulverize the ground, as alſo to deſtroy weeds; ſo that the land is rendered much better for corn, after a crop of Beans, than it would have been before, eſpecially if they are ſown and managed according to the new huſbandry, with a drill plough, and the horſe hoe, uſed to ſtir the ground between the rows of Beans, which will prevent the growth of weeds, and pulverize the ground, whereby a much greater crop of Beans may, with more certainty, be expected, and the land will be better prepared for whatever crop it is deſigned for after.

The ſeaſon for ſowing of theſe Beans is from the middle of February to the end of March, according to the nature of the ſoil; the ſtrongeſt and wet land ſhould always be laſt ſown; the uſual quantity of Beans ſown on an acre of land is about three buſhels; but this is double the quantity which need be ſown, eſpecially according to the new huſbandry; but I ſhall firſt ſet down the practice according to the old huſbandry, and then give directions for their management according to the new. The method of ſowing is after the plough, in the bottom of the furrows; but then the furrows ſhould not be more than five, or at moſt ſix inches deep. If the land is new broken up, it is uſual to plough it early in autumn, and let it lie in ridges till after Chriſtmas; then plough it in ſmall furrows, and lay the ground ſmooth; theſe two ploughings will break the ground fine enough for Beans, and the third ploughing is to ſow the Beans, when the furrows ſhould be made ſhallow, as was before mentioned.

Moſt people ſet their Beans too cloſe; for, as ſome lay the Beans in the furrows after the plough, and others lay them before the plough, and plough them in; ſo, by both methods the Beans are ſet as cloſe as the furrows are made, which is much too near; for when they are on ſtrong good land, they generally are drawn up to a very great height, and are not ſo apt to pod as when they have more room, and are of lower growth; therefore I am convinced by many late trials, that the better way is to make the furrows two feet and a half aſunder, or more; which will cauſe them to branch out into many ſtalks, and bear in greater plenty than when they are cloſer; by this method, half the quantity of Beans will be ſufficient for an acre of land; and by the ſun and air being admitted between the rows, the Beans will ripen much earlier and more equally than in the common way.

What has been mentioned muſt be underſtood as relating to the old huſbandry; but where Beans are planted according to the new, the ground ſhould be four times ploughed before the Beans are ſet, which will break the clods, and render it much better for planting; then with a drill plough, to which a hopper is fixed for ſetting of the Beans, the drills ſhould be made at three feet aſunder, and the ſpring of the hopper ſet ſo as to ſcatter the Beans at three inches diſtance in the drills. By this method leſs than one buſhel of ſeed will plant an acre of land. When the Beans are up, if the ground is ſtirred between the rows with a horſe plough, it will deſtroy all the young weeds; and when the Beans are advanced about three or four inches high, the ground ſhould be again ploughed between the rows, and the earth laid up to the Beans; and if a third ploughing, at about five or ſix weeks after is given, the ground will be kept clean from weeds, and the Beans will ſtalk out, and produce a much greater crop than in the common way.

When the Beans are ripe, they are reaped with a hook, as is uſually practiſed for Peas; and after having lain a few days on the ground they are turned, and this muſt be repeated ſeveral times, until they are dry enough to ſtack; but the beſt method is to tie them in ſmall bundles, and ſet them upright; for then they will not be in ſo much danger to ſuffer by wet, as when they lie on the ground; and they will be more handy to carry and ſtack, than if they are looſe. The common produce is from twenty to twenty-five buſhels on an acre of land; but I have known thirty-ſix on an acre.

The Beans ſhould lie in the mow to ſweat, before they are threſhed out; for as the haulm is very large and ſucculent, ſo it is very apt to give and grow moiſt; but there is no danger of the Beans receiving damage, if they are ſtacked tolerably dry, becauſe the pods will preſerve the Beans from injury; and they will be much eaſier to threſh after they have ſweat in the mow than before; and after they have once ſweated and are dry again, they never after give.

By the new huſbandry, the produce has exceeded the old by more than ten buſhels on an acre; and if the Beans which are cultivated in the common method are obſerved, it will be found that more than half their ſtems have no Beans on them; for by ſtanding cloſe, they are drawn up very tall; ſo the tops of the ſtalks only produce, and all the lower part is naked; whereas in the new method, they bear almoſt to the ground; and as the joints of the ſtems are ſhorter, ſo the Beans grow cloſer together on the ſtalks.

In the year 1745 I made the following experiment, in planting a piece of eleven acres of Beans in Berkſhire, viz. the gentleman's bailiff, who was wedded to the old practice of huſbandry, was very unwilling to depart from it; and having been an old ſervant in the family, his maſter was inclinable to hear all he could ſay in favour of his opinion: however, at laſt I prevailed on the gentleman to let his bailiff plant one half of the land in his way, giving him the choice which half he would have: accordingly the land was divided and planted; but the ſummer proving wet, the Beans on that part of the field he had choſen grew ſo tall and rank, that they produced no pods but on the upper part of the ſtalks; and when they were threſhed out, there was no more than twenty-two buſhels on an acre, whereas the other half produced near forty.

FABA ÆGYPTIACA, is the Arum Ægyptiacum.

FABA CRASSA, is Anacampſeros.

FABAGO. See ZYGOPHYLLUM.

FAGARA. Brown. Hiſt. Jam. tab. 5. f. 1. Ironwood.

The CHARACTERS are,

It hath male and hermaphrodite flowers upon different plants; the male flowers have a ſmall empalement, ſlightly cut into four ſegments, but have no petals, and ſix ſtamina, terminated by roundiſh ſummits: theſe are barren. The female flowers have a larger concave permanent empalement with four ſpreading petals, and four ſtamina, crowned with oval ſummits, and an oval germen, ſupporting a ſlender ſtyle, terminated by an obtuſe ſtigma; the germen afterward becomes a globular capſule with two lobes, incloſing two ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia; whereas it ſhould be put into his ſixth ſection of the twenty-third claſs, as the flowers are male and hermaphrodite on different plants, and the flowers have ſix ſtamina: but this miſtake he was led into by Jacquin, who had ſeen and deſcribed the hermaphrodite flowers only.

The SPECIES are,

1. FAGARA (*Pterota*) foliolis emarginatis. Amœn. Acad. 5. p. 393. *Fagara, whoſe lobes (or ſmall leaves) are indented at the top.* Lauro affinis jaſmini alato folio, coſta media membranulis utrinque extantibus alata, ligno duritie ferro vix cedens. Sloan. Hiſt. Jam. 2. p. 25. *Ironwood.*
2. FAGARA (*Tragodes*) articulis pinnarum ſubtus aculeatus. Jacq. Amer. 13. *Fagara with ſpines under the leaves at the joints.* Schinoides petiolis ſubtus aculeatis. Hort. Cliff. 489.

The firſt ſort grows naturally in the warmeſt parts of America. The late Dr. Houſtoun found it growing at Campeachy, from whence he ſent me dried ſpecimens of the plants in flower, by which I am convinced there are male trees which are barren. It riſes with a woody ſtem upwards of twenty feet high, ſending out branches great part of its length, garniſhed with ſmall winged leaves, having three or five lobes to each. The flowers come from the ſide of the branches, ſtanding four or five together upon ſhort foot-ſtalks.

The ſecond ſort I have placed here after Linnæus, but am not ſure it ſhould be ranged with it; for although I have pretty ſtrong plants of it growing in the Chelſea garden, they have not yet flowered; but by the external face of the plant, it ſeems to agree with the firſt.

Theſe are both tender plants, ſo muſt be kept in the bark-ſtove conſtantly, and are propagated by ſeeds, and alſo by cuttings, if properly managed.

FAGONIA. Tourn. Inſt. R. H. 265. tab. 141. Lin. Gen. Plant. 475. This plant was ſo named by Dr. Tournefort, in honour of Dr. Fagon, who was ſuperintendant of the royal garden at Paris.

The CHARACTERS are,

The flower hath a ſpreading empalement, compoſed of five ſmall leaves; it hath five heart-ſhaped petals, which ſpread open, aud are narrow at their baſe, where they are inſerted in the empalement. It hath ten ſtamina which are erect, terminated by roundiſh ſummits. In the center is ſituated a five-cornered germen, ſupporting an awl-ſhaped ſtyle, crowned by a ſingle ſtigma. The germen afterward becomes a roundiſh capſule having five lobes, ending in a point, and five cells, each having a ſingle roundiſh ſeed.

Linnæus ranges this plant in the firſt ſection of his tenth claſs, intitled Decandria Monogynia, from the flower having ten ſtamina and one ſtyle.

The SPECIES are,

1. FAGONIA (*Erecta*) ſpinoſa, foliolis lanceolatis planis lævibus. Hort. Upſal. 103. *Prickly Fagonia, whoſe leaves are ſpear-ſhaped, plain, and ſmooth.* Fagonia Cretica ſpinoſa. Tourn. *Thorny Trefoil of Candia.*
2. FAGONIA (*Hiſpanica*) inermis. Lin. Sp. Plant. 386. *Fagonia without ſpines.* Fagonia Hiſpanica non ſpinoſa. Tourn. *Spaniſh Fagonia without thorns.*
3. FAGONIA (*Arabica*) ſpinoſa, foliolis linearibus convexis. Lin. Sp. Plant. 386. *Prickly Fagonia with narrow convex leaves.* Fagonia Arabica, longiſſimis aculeis armato. Shaw. Pl. Afr. 229. *Arabian Fagonia, armed with very long ſpines.*

The firſt ſort is a native of the iſland of Candia: this has been deſcribed by ſome botaniſts under the title of Trifolium ſpinoſum Creticum, which occaſioned my giving it the Engliſh name of Thorny Trefoil of Crete; though there is no other affinity between this and the Trefoil, than that of this having three leaves or lobes on the ſame foot-ſtalk.

This is a low plant, which ſpreads its branches cloſe to the ground, which are extended to the length of a foot or more every way, garniſhed with ſmall trifoliate oval leaves, placed oppoſite; and at each joint, immediately below the leaves, come out two pair of ſpines, one on each ſide the ſtalk; and at the ſame places come out a ſingle blue flower, ſtanding upon a ſhort foot-ſtalk, compoſed of five ſpear-ſhaped petals, which are narrow at their baſe, where they are inſerted into the empalement; after theſe fall away, the germen turns to a roundiſh five-lobed capſule, ending in an acute point, having five cells, each containing one roundiſh ſeed. It flowers in July and Auguſt, but unleſs the ſeaſon proves warm, the ſeeds do not ripen in England.

The ſecond ſort grows naturally in Spain; this differs from the firſt in being ſmooth, the branches of this having no thorns; and the plant will live two years, whereas the firſt is annual.

The third ſort was diſcovered by the late Dr. Shaw in Arabia; this is a low plant with a ſhrubby ſtalk, from which come out ſeveral weak branches armed with long thorns; the leaves of this are thick, narrow, and convex on their lower ſide; the flowers come out in the ſame manner as in the firſt ſort.

Theſe plants are propagated by ſeeds, which ſhould be ſown upon a border of freſh light earth, where the plants are deſigned to remain, for they do not bear tranſplanting well; when the plants come up, they may be thinned out to the diſtance of ten inches or a foot; and if they are kept clean from weeds, they will require no other care.

The firſt ſort is an annual plant, which ſeldom perfects its ſeeds in England, unleſs the ſeaſons prove very warm; therefore the beſt way is to ſow the ſeeds upon a warm border in the autumn, and in froſty weather ſhelter the plants with mats, or ſome covering to ſecure them; or if they are ſown in pots and placed under a frame in the winter, and the following ſpring ſhaken out of the pots, and planted in a warm border, they will come early to flower, and thereby ripe ſeeds may be more certainly obtained.

The other two ſorts may be treated in the ſame way; for as theſe ſeldom flower the firſt year from ſeeds, ſo the plants ſhould be either kept in pots, and ſheltered under a frame in winter, or placed in a warm border, where they may be ſheltered with mats, or ſome other covering, to preſerve them from the froſt; and the following ſummer the ſecond ſort will flower and produce ripe ſeeds, but the third has not perfected any ſeeds as yet in England.

FAGOPYRUM. See Helxine.

FAGUS. Tourn. Inſt. R. H. 584. tab. 351. Lin. Gen. Plant. 951. [ſo called from φάγω, *Gr.* becauſe ſuppoſed to be the food of the firſt race of mankind.] The Beech-tree; in French, *Hêtre.*

The Characters are,

It hath male and female flowers on the ſame tree; the male flowers are collected into globular heads; theſe have no petals, but have ſeveral ſtamina included in an empalement of one leaf; which are terminated by oblong ſummits. The female flowers have a one-leaved empalement cut into four parts, but have no petals; the germen is fixed to the empalement, ſupporting three ſtyles, crowned by reflexed ſtigmas. The germen afterward becomes a roundiſh capſule, armed with ſoft ſpines, opening in three cells, each containing a triangular nut.

This genus of plants is ranged in the eighth ſection of Linnæus's twenty-firſt claſs, which includes thoſe plants that have male and female flowers on the ſame plant, and the male flowers have many ſtamina. To this genus he has joined the Cheſnut; but as the male flowers of the Cheſnut are collected in long katkins, and thoſe of the Beech are globular, and the fruit of the latter being triangular, there is ſufficient reaſon for keeping them ſeparate.

We know but one Species of this genus, viz.

Fagus (*Sylvatica*) foliis ovatis obſolete ſerratis. Hort. Cliff. 447. Fagus. Dod. Pempt. 832. *The Beech-tree with oval ſawed leaves.*

There are ſome planters, who ſuppoſe there are two diſtinct ſpecies of this tree; one they call the Mountain Beech, which they ſay is a whiter wood than the other, which they diſtinguiſh by the title of Wild Beech; but it is certain, that this difference in the colour of the wood ariſes from the difference of the ſoils in which they grew, for I have not ſeen any ſpecific difference in the trees. There have been ſeeds of a Beech-tree brought from North-America, by the title of Broad-leaved Beech, but the plants which were raiſed from them proved to be the common ſort; ſo that we know of no other variety, excepting thoſe with ſtriped leaves, which is accidental; and when the trees are in vigour, the leaves become plain again.

This tree is propagated by ſowing the maſt; the ſeaſon for which is any time from October to February, only obſerving to ſecure the ſeeds from vermin when early ſowed; which, if carefully done, the ſooner they are ſown the better, after they are full ripe: a ſmall ſpot of ground will be ſufficient for raiſing a great number of theſe trees from ſeed, but you muſt be very careful to keep them clear from weeds; and if the plants come up very thick, you ſhould not fail to draw out the ſtrongeſt of them the autumn following, that thoſe left may have room to grow; ſo that if you huſband a ſeed-bed carefully, it will afford a three years draught of young plants, which ſhould be planted in a nurſery; and, if deſigned for timber trees, at three feet diſtance row from row, and eighteen inches aſunder in the rows.

But if they are deſigned for hedges (to which the tree is very well adapted) the diſtance need not be ſo great; two feet row from row, and one foot in the rows will be ſufficient. In this nurſery they may remain two or three years, obſerving to clear them from weeds, as alſo to dig up the ground between the rows, at leaſt once a year, that their tender roots may the better extend themſelves each way: but be careful not to cut or bruiſe their roots, which is injurious to all young trees; and never dig the ground in ſummer, when the earth is hot and dry; which, by letting in the rays of the ſun to the roots, is often the deſtruction of young trees.

This tree will grow to a conſiderable ſtature, though the ſoil be ſtony and barren; as alſo upon the declivities of hills, and chalky mountains, where they will reſiſt the winds better than moſt other trees; but then the nurſeries for the young plants ought to be upon the ſame ſoil; for if they are raiſed in good ſoil and a warm expoſure, and afterwards tranſplanted into a bleak barren ſituation, they ſeldom thrive, which holds true in moſt other trees; therefore I would adviſe the nurſery to be made upon the ſame ſoil where the plantation is intended, but of this I ſhall ſay more under the article of Nursery.

The tree is very proper to form large hedges to ſurround plantations, or large wilderneſs quarters; and may be kept in a regular figure, if ſheared twice a year, eſpecially if they ſhoot ſtrong; in which caſe, if they are neglected but a ſeaſon or two, it will be difficult to reduce them again. The ſhade of this tree is very injurious to moſt ſorts of plants which grow near it, but is generally believed to be very ſalubrious to human bodies.

The timber is of great uſe to turners for making trenchers, diſhes, trays, buckets; and likewiſe to the joiner for ſtools, bedſteads, coffins, &c. The maſt is very good to fat ſwine and deer; it alſo affords a ſweet oil, and the nuts have in ſcarce times ſupported ſome families with bread.

This tree delights in a chalky or ſtony ground, where it generally grows very faſt; and the bark of the trees in ſuch land is clear and ſmooth; and although the timber is not ſo valuable as that of many other trees, yet as it will thrive on ſuch ſoils and in ſuch ſituations where few better trees will ſcarce grow, the planting of them ſhould be encouraged; eſpecially as the trees afford an agreeable ſhade, and the leaves make a fine appearance in ſummer, and continue green as long in autumn as any of the deciduous trees: therefore in parks, and other plantations for pleaſure, this tree deſerves to be cultivated among thoſe of the firſt claſs, eſpecially where the ſoil is adapted to it.

The two ſorts with variegated leaves may be propagated by budding or grafting them upon the common Beech, obſerving not to plant them in a good earth; which will cauſe the buds or cyons to ſhoot vigorouſly, whereby the leaves will become plain, which often happens to moſt variegated plants.

FARINA FŒCUNDANS is the impregnating meal or duſt on the apices or ſummits of flowers; which, being conveyed into the uterus or vaſculum ſeminale of plants, fecundates the rudiments of the ſeeds in the ovary, which otherwiſe would decay and come to nothing. See Generation of Plants.

FEATHERFEW, or FEAVERFEW. See Matricaria.

FENCES. In hotter climates than England, where they have not occaſion for walls to ripen their fruit, their gardens lie open, where they can have water fence and proſpects; or elſe they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleaſing to the ſight than a dead wall: but in colder countries, and in England, we are obliged to have walls to ſhelter and ripen our fruit, although they take away much from the pleaſant proſpect of the garden.

Since therefore we are under a neceſſity to have walls to ſecure our gardens from the injury of winds, as well as for the conveniency of partitions or incloſures, and alſo to ripen our fruit, brick walls are accounted the warmeſt and beſt for this purpoſe: and theſe walls being built pannel-ways, with pillars at equal diſtances, will ſave a great deal of charge, in that the walls may be built thinner, than if they were built plain without theſe pannels, for then it would be neceſſary to build them thicker every where: and beſides, theſe pannels make the walls look the handſomer.

Stone walls are by ſome preferred to thoſe of brick, eſpecially thoſe of ſquare hewn ſtones; but where they are deſigned for fruit, they ſhould be faced with brick. Thoſe that are made of rough ſtones, though they are very dry and warm, yet, by reaſon of their unevenneſs, are inconvenient to nail up trees to, except pieces of timber be laid in them here and there for to faſten a trellis to them.

But in large gardens it is better to have the proſpect open to the pleaſure-garden, which ſhould be ſurrounded with a foſſe, that from the garden the adjacent country may be viewed, but this muſt depend on the ſituation of the place; for if the proſpect from the garden is not good, it had better be ſhut out from the ſight by a wall, or any other fence, than to be open. As alſo, where a garden lies near a populous town, and the adjoining grounds are open to the inhabitants, if the garden is open, there will be no walking there in good weather, without being expoſed to the view of all paſſengers, which is very diſagreeable.

Where theſe foſſes are made round a garden which is ſituated in a park, they are extremely proper; becauſe hereby the proſpect of the park will be obtained in the garden, which renders theſe gardens much more agreeable than thoſe which are confined.

In the making theſe foſſes there have been many inventions; but, upon the whole, I have not ſeen any which are in all reſpects preferable to thoſe which have an upright wall next the garden; which (where the ſoil will admit of a deep trench) ſhould be ſix or ſeven feet high, ſo as to be above the reach of boys; and from the foot of this wall, the ground on the outſide ſhould riſe with a gradual eaſy ſlope to the diſtance of eighteen or twenty feet; and where it can be allowed, if it ſlopes much farther, it will be eaſier and leſs perceptible as a ditch to the eye, when viewed at a diſtance. But if the ground is naturally wet, ſo as not to admit of a deep foſſe, then, in order to make a fence againſt cattle, if the wall be four feet high, and ſlight poſts of three feet and a half high are placed juſt behind the wall, with a ſmall chain carried on from poſt to poſt, no cattle or deer will ever attempt to jump againſt it, therefore it will be a ſecure fence againſt them; and if theſe are painted of a dark lead colour, they will not be diſcerned at a diſtance; and at the ſame time the chain will ſecure perſons walking in the garden from tumbling over: and if another chain is carried through the poſts at one foot from the ground, it will more effectually prevent cattle from creeping under.

In ſuch places where there are no good proſpects to be obtained from a garden, it is common to make the incloſure of park-paling; which, if well performed, will laſt many years, and has a much better appearance than a wall: and this pale may be hid from the ſight within, by plantations of ſhrubs and Evergreens; or there may be a quick hedge planted within the pale, which may be trained up, ſo as to be an excellent fence by the time the pales begin to decay.

There are ſome perſons who make ſtuckade fences round their gardens to keep out cattle, &c. which, when well made, will anſwer the purpoſe of a fence; but this being very expenſive in the making, and not of very long duration, has occaſioned their not being more commonly in uſe.

As to fences round parks, they are generally of paling; which, if well made of winter-fallen Oak, will laſt many years; but a principal thing to be obſerved in making theſe pales, is not to make them too heavy; for when they are ſo, their own weight will cauſe them to decay; therefore the pale ſhould be cleft thin, and the rails ſhould be cut triangular, to prevent the wet lodging upon them; and the poſts ſhould be good, and not placed too far aſunder, burning that part of them as goes into the ground. If theſe things are obſerved, one of theſe pales will laſt, with a little care, upward of forty years very well. The common way of making theſe fences is, to have every other pale nine or ten inches above the intermediate ones; ſo that the fence may be ſix feet and a half high, which is enough for fallow deer; but where there are red deer, the fence ſhould be one foot higher, otherwiſe they will leap over.

Some incloſe their parks with brick walls; and in countries where ſtone is cheap, the walls are built with this material; ſome with, and others without mortar.

A kitchen-garden, if rightly contrived, will contain walling enough to afford a ſupply of ſuch fruits as require the aſſiſtance of a wall for any family; and this garden being ſituated on one ſide, and quite out of ſight of the houſe, may be ſurrounded with walls, which will ſcreen the kitchen-garden from the ſight of perſons in the pleaſure-garden; and being locked up, the fruit will be much better preſerved than it can be in the public garden: and the having too great a quantity of walling is often the occaſion that ſo many ſcandalous trees are frequently to be ſeen in large gardens, where there is not due care obſerved in their management.

And beſides, the borders of pleaſure-gardens are generally too narrow for the roots of fruit-trees, as will be ſhewn in its proper place, therefore it is in vain to plant them there.

The height of garden-walls ſhould be from ten to twelve feet, which is a moderate proportion; and if the ſoil be good, it may in time be well furniſhed with bearing wood in every part, eſpecially thoſe parts planted with Pears, notwithſtanding the branches being trained horizontally from the bottom of the walls.

I would recommend the White Thorn, the Holly, the Black Thorn and Crab, for outward fences to a good ground, but I do not approve of the intermixing them.

The White Thorn is the beſt quick to plant, becauſe it is the moſt common, and may be clipped ſo as to render it the cloſeſt and hardieſt fence of any other tree; and being very durable, is preferred to all others for outward fences, or for the diviſion of fields, where they are expoſed to cattle, &c.

The Black Thorn and Crab make very good fences, and are to be raiſed as the White Thorn; but if the kernels of Apples or Crabs be ſown, it is beſt to ſow the pommace with them, and they will come up the ſooner, i. e. the firſt year, if ſown in the autumn, ſoon after the fruit is ripe.

If Crab-ſtocks be planted while young, in the ſame manner as quick, they make excellent hedges ſoon, and ſo will ſome ſorts of Plumbs, I mean ſuch as have thorns.

The Black Thorn is not accounted ſo good for fences as the White Thorn, becauſe it is apt to run more into the ground, and is not certain as to the growing, eſpecially if the plants are not ſet very young; but then on the other hand, the buſhes are by much the better, and are alſo more laſting than the White Thorn, or any other, for dead hedges, or to mend gaps; nor are they ſubject to be cropt by cattle, as the others are. The richer the mould is, the better they will proſper, but yet they will grow on the ſame ſort of ſoil that the White Thorn does.

The Holly will make an excellent fence, and is preferable to all the reſt, but is a ſlow grower; but when once it does grow, it makes amends by its height, ſtrength, and thickneſs.

It is raiſed of young ſeedling plants or berries, as the White Thorn is, and the berries will lie as long in the ground before they come up. It delights moſt in ſtrong grounds, but will grow upon the drieſt gravel, amongſt rocks and ſtones.

The berries lie till the ſecond ſpring before they come up, therefore they ſhould be prepared before they are ſown (for this ſee the article AQUIFOLIUM.) It will be beſt to ſow them in the place where you deſign they ſhould grow, but they ſhould be well weeded both before they come up and afterwards.

French Furz will alſo do well upon dry ſandy banks, where few other plants will grow; but they muſt be kept very clean at the bottom, and cut thin, and never ſuffered to grow too high: nor ſhould they be cut in dry weather, or late in autumn, nor early in the ſpring; the doing either of which is ſubject to make it die in patches, which is irrecoverable; nor will it ever break out again from old wood, if cut cloſe in, after it has been ſuffered long to grow out.

Fences may likewiſe be made of Elder: if the ſoil be any thing good, you may put ſticks of Elder, or truncheons ten or twelve feet long, ſlopeways in your banks, ſo as to make a chequer-work; and they will make a fence for a garden the quickeſt of any thing, and be a good ſhelter. But theſe fences are improper for a fine garden, becauſe they ſhoot very irregular, and are ungovernable; as likewiſe the roots of theſe trees ſpread very far, and draw away all the heart of the ground, ſo as to ſtarve whatever plants grow near them: and add to this the ſcattering of the berries, which will fill the ground near them with young plants; which, if not timely weeded out, will get the better of whatever grows near them; therefore this ſort of fence is ſeldom planted, where a hedge of White Thorn can be had.

Elder planted on a bank, the ſide of which is waſhed with a river or ſtream, will make an extraordinary fence, and will preſerve the bank from being undermined by the water, becauſe it is continually ſending ſuckers from the roots and lower branches, which is of great advantage where the ſtream waſhes away the bank.

For middle fences in a garden, the Yew is the moſt tonſile, governable, and durable plant.

For ſurrounding wilderneſs quarters, Elm, Lime, Hornbeam and Beech, are very proper.

FENNEL. See Foeniculum.

FENNEL-FLOWER. See Nigella.

FERRUM EQUINUM. See Hippocrepis.

FERULA. Lin. Gen. Plant. 305. Tourn. Inſt. R. H. 321. tab. 170. [takes its name of Ferendo, *Lat.* becauſe the ſtalks of this plant are made uſe of in ſupporting the branches of trees; or of Feriendo, becauſe in old time ſticks were made of them, with which ſchool-maſters uſed to correct their ſcholars.] Fennel Giant; in French, *Ferule.*

The Characters are,

It hath an umbellated flower; the principal umbel is globular, and is compoſed of ſeveral ſmaller called rays, of the ſame form; the involucrum is compoſed of ſeveral narrow leaves which fall off; the principal umbel is uniform. The flowers have five oblong erect petals which are equal, and five ſtamina of the ſame length, terminated by ſingle ſummits; under the flower is ſituated a turbinated germen, ſupporting two reflexed ſtyles, crowned by obtuſe ſtigmas. The germen afterward becomes an elliptical, compreſſed, plain fruit, dividing in two parts, each having a large elliptical plain ſeed, marked with three lines on each ſide.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, which contains thoſe plants whoſe flowers have five ſtamina and two ſtyles.

The Species are,

1. Ferula (*Communis*) foliolis linearibus longiſſimis ſimplicibus. Hort. Cliff. 95. *Ferula with the ſmaller leaves, very narrow, long, and ſingle.* Ferula major, ſeu fæmina Plinii. M. Umb. *Pliny's Female Fennel Giant.*
2. Ferula (*Galbanifera*) foliolis multipartitis, laciniis linearibus planis. Hort. Cliff. 95. *Ferula whoſe ſmaller leaves are divided into many narrow parts which are plain.* Ferula galbanifera. Lob. Obſ. *Galbanum-bearing Fennel Giant.*
3. Ferula (*Tingitana*) foliolis laciniatis, lacinulis tridentatis inæqualibus. Hort. Cliff. 95. *Ferula whoſe ſmaller leaves are cut, and ſegments ending in three unequal parts.* Ferula Tingitana, folio latiſſimo lucido. H. Edin. *Broad-leaved ſhining Fennel Giant from Tangier.*
4. Ferula (*Ferulago*) foliis pinnatifidis, pinnis linearibus planis trifidis. Hort. Cliff. 95. *Ferula with wing-pointed leaves, whoſe pinnæ are narrow, plain, and trifid.* Ferula latiore folio. Mor. Hiſt. 3. p. 309. *Fennel Giant with a broader leaf.*
5. Ferula (*Orientalis*) foliorum pinnis baſi nudis, foliolis ſetaceis. Hort. Cliff. 95. *Ferula with the wings of the leaves naked at the baſe, and the ſmaller leaves briſtly.* Ferula Orientalis, Cachyros folio & facie. Tourn. Cor. 22. *Eaſtern Fennel Giant with the leaf and appearance of Cachrys.*
6. Ferula (*Meoides*) foliorum pinnis utrinque baſi acutis, foliolis ſetaceis. Hort. Cliff. 95. *Ferula with the wings of the leaves pointed at their baſe on every ſide.* Laſerpitium Orientale mei folio, flore luteo. Tourn. Cor. 23. *Eaſtern Laſerwort with a Spignel leaf and yellow flower.*
7. Ferula (*Nodiflora*) foliolis appendiculatis, umbellis ſubſeſſilibus. Lin. Sp. Plant. 247. *Ferula with appendages to the ſmaller leaves, and umbels ſitting cloſe to the ſtalks.* Libanotis ferulæ folio & ſemine. C. B. P. 158. *Libanotis with a Fennel Giant leaf and ſeed.*
8. Ferula (*Glauca*) foliis ſupradecompoſitis, foliolis lanceolato-linearibus planis. Hort. Cliff. 95. *Fennel Giant with linear, ſpear-ſhaped, decompounded leaves.* Ferula folio glauco, ſemine lato oblongo. J. B. 3. p. 45.

The firſt of theſe plants is pretty common in the Engliſh gardens: this, if planted in a good ſoil, will grow to a great height, and divide into many branches: the lower leaves of this ſort ſpread more than two feet every way, and branch out into many diviſions, which are again ſubdivided into many ſmaller, garniſhed with very long, narrow, ſmall leaves that are ſingle; they are of a lucid green, and ſpread near the ground. From the center of the plant comes out the flower-ſtalk, which, when the plants are ſtrong, will be near as large as a common broomſtick, and will riſe ten or twelve feet high, having many joints; if the ſtalks are cut, there iſſues from the veſſels a fœtid yellowiſh liquor, which will concrete on the ſurface of the wound. The ſtalks are terminated by large umbels of yellow flowers, which come out the latter end of June, or in the beginning of July; theſe are ſucceeded by oval compreſſed ſeeds, which have three lines running longitudinally on each ſide. Theſe ripen in September, and the ſtalks decay ſoon after. When the ſtalks are dry, they are full of a light dry pith, which will ſoon take fire.

Mr. Ray ſays, that the people of Sicily uſe the pith of this plant for tinder to light their fires. And if this was practiſed by the ancients, we may eaſily gueſs why the poets feigned, that Prometheus ſtole fire from heaven, and carried it to the earth in a hollow Ferula.

The leaves of theſe plants decay ſoon after the ſeeds are formed, ſo that before they are ripe, there are ſeldom any leaves remaining, and the ſtalks afterward dry and become very tough; ſo it is not unlikely theſe may have been uſed for correction in the ſchools, as they are very light, and cannot do much injury. The roots of this ſort will continue ſeveral years, eſpecially on a dry ſoil, and will annually produce flowers and ſeeds.

The ſecond ſort doth not grow quite ſo large as the firſt, but the ſtalks of this will riſe ſeven or eight feet high; the lower leaves are large, and greatly divided; the ſmall leaves are flat, and not ſo long as thoſe of the former, and are of a lucid green colour; the umbels of flowers are ſmaller, and the ſeeds are leſs. This flowers and ripens its ſeeds about the ſame time as the former ſort.

The third ſort hath large ſpreading leaves near the root, which are divided and ſubdivided into many parts; the ſmall leaves of this are much broader than in any of the other ſorts, and theſe are divided at their end into three unequal ſegments; the leaves are of a very lucid green. The ſtalks are ſtrong, and riſe to the height of eight or ten feet, and are terminated by large umbels of yellow flowers, which are ſucceeded by large, oval, compreſſed ſeeds, like thoſe of the firſt ſort. This flowers and ripens its ſeeds about the ſame time as the former ſort; it grows naturally in Spain and Barbary.

The fourth ſort grows to much the ſame height as the ſecond; the leaves of this branch out on every ſide pretty wide, and the ſmaller leaves on the diviſions of the leaves, are broader than thoſe of the others (excepting the third) but they are longer than thoſe, and are of a darker green colour, ending in three points. The umbels of flowers are large, the flowers are yellow, and are ſucceeded by oval compreſſed ſeeds, like thoſe of the other ſpecies. This grows naturally in Sicily.

The fifth ſort is of much humbler growth than either of the former; the ſtalks of this ſeldom riſe much more than three feet high; the lower leaves branch into many diviſions, which are cloſely garniſhed with very fine briſtly leaves; the umbel of flowers is but ſmall, when compared with the others, and the ſeeds are ſmaller. It grows naturally in the Levant.

The ſixth ſort hath very branching leaves, the footſtalks are angular and channelled; this ſends out at every joint two ſide branches oppoſite; thoſe toward the bottom are nine or ten inches long, and the others are diminiſhed gradually to the top; theſe ſide branches ſend out ſmaller at each joint in the ſame manner, which are garniſhed with very fine leaves like thoſe of Spignel, which ſtand quite round the ſtalks in ſhape of whorls; the flower-ſtalks grow three feet high, having a pretty large umbel of yellow flowers at the top; theſe are ſucceeded by oval flat ſeeds, which ripen in the autumn. It grows naturally in the Levant.

The ſeventh ſort riſes about three feet high; the leaves of this ſort are much divided, and the ſmall leaves on the diviſions are very narrow and entire; the umbels of flowers are ſmall, and are ſituated cloſe to the ſtalks between the leaves at the joints; theſe are like thoſe of the other ſorts. It grows naturally in Iſtria and Carniola.

The eighth ſort grows naturally in Italy and Sicily. The leaves of this are compoſed of many narrow flat ſegments, of a gray colour, and are divided into many parts: the ſtalk riſes from three to four feet high, and is terminated by an umbel of yellow flowers in July, which are ſucceeded by oval compreſſed ſeeds which ripen in autumn.

All theſe ſorts have perennial roots, which will continue ſeveral years; theſe have thick ſtrong fibres, which run deep in the ground, and divide into many ſmaller, ſpreading to a conſiderable diſtance every way: the ſtalks are annual, and decay ſoon after they have perfected their ſeeds. As theſe plants ſpread very wide, ſo they ſhould have each four or five feet room; nor ſhould they ſtand near to other plants, for their roots will rob whatever plants grow near them of their nouriſhment.

They are all propagated by ſeeds, which ſhould be ſown in the autumn; for if they are kept out of the ground till the ſpring, they frequently fail, and thoſe which ſucceed remain a year in the ground, ſo that much time is loſt. The ſeeds may be ſown in drills, by which method the ground may be eaſier kept clean; they muſt not be nearer than a foot row from row, and the ſeeds may be ſcattered two or three inches aſunder in the drills; when the plants come up, they muſt be kept clean from weeds; and where they are too cloſe together, they ſhould be thinned, to allow them room to grow, for they will not be ſtrong enough to remove till they have had two years growth; then in the autumn ſo ſoon as their leaves decay, the roots ſhould be taken up with great care, ſo as not to cut or injure the tap or downright root, and then planted in the places where they are deſigned to remain, for after this tranſplanting they ſhould not be removed. They delight in a ſoft, gentle, loamy ſoil, not too wet, and are very rarely injured by the hardeſt froſt.

FERRARIA. Burman. Lin. Gen. 1018.

The Characters are,

It hath two keel-ſhaped ſpathæ (*or ſheaths*) *which alternately incloſe the flowers, which have ſix oblong pointed petals curled at their borders, revolving, and are alternately larger; and three ſtamina ſitting on the ſtyle, terminated by twin roundiſh ſummits; and a roundiſh three-cornered germen under the flower, ſupporting a ſimple erect ſtigma, crowned by three bifid, hooded, curled ſtigma; the germen afterward becomes an oblong three-cornered capſule, having three cells, filled with roundiſh ſeeds.*

This genus of plants is ranged in the ſecond ſection of Linnæus's twentieth claſs, intitled Gynandria triandria, the flower having three ſtamina which ſit upon the ſtyle.

The Species are,

1. Ferraria (*Undulata*) foliis lanceolatis. Burm. Icon. *Ferraria with ſpear-ſhaped leaves.* Iris ſtellata, Cyclaminis radice, pullo flore. Barrel. Icon. 1216. *Starry Iris with a root like the Sowbread.*
2. Ferraria (*Enſiformi*) foliis enſiformibus. Burm. Icon. *Ferraria with ſword-ſhaped leaves.*

Theſe plants grow naturally at the Cape of Good Hope; the roots of the firſt ſort were ſent me by Dr. Job Baſter, of Zirkzee, who received them from the Cape. The root of this is ſhaped like that of the Bizantine Cornflag; it has a bright brown ſkin or cover; on the upper ſide is a hollow like a navel, from whence the flower-ſtalk ariſes. The ſtalk riſes a foot and a half high, and is about the ſize of a man's middle finger, garniſhed with leaves the whole length; theſe are keel-ſhaped, embracing the ſtalks with their baſe. The upper part of the ſtalk divides into two or three branches, which are garniſhed with the ſame ſhaped leaves, but they are ſmaller; each of the branches are terminated by a large ſpathæ or ſheath of the ſame colour with the leaves, but this afterward withers and decays; theſe ſheaths are double, and ſplit at the top, where the flower peeps out its petals; theſe ſix petals are three alternately larger than the other, and are curiouſly fringed on their borders; they are of a pale greeniſh colour on their outſide, but of a tawney purple within, and are of a ſhort duration; in the centre of the flower is ſituated the ſtyle, having the three ſtamina fixed on the ſide, and is terminated by twin ſtigmas; the germen is ſituated under the flower, which afterward becomes an oblong ſmooth capſule with three cells, filled with roundiſh ſeeds.

The ſecond ſort is rare in England; this differs from the former in having ſmaller roots, and longer ſword-ſhaped leaves, which have deeper veins; the ſtalk alſo does not divide ſo much, and the flowers are ſmaller, and leſs fringed on their borders.

They are both propagated by offſets ſent out from the roots, in the ſame way as the Ixia, and ſhould be cultivated in the ſame manner as is directed for thoſe and the African Gladiolus, being too tender to thrive in the open air in England, nor do they ſucceed well in a green-houſe; therefore the beſt method is, to make a border four feet wide, either in the front of the green-houſe or ſtoves, covering it with a proper frame and glaſſes, ſo that the plants may enjoy the free air in mild weather, but be protected from froſt. In ſuch a frame, moſt of the African bulbous and tuberous rooted plants may be brought to great perfection.

There is a great ſingularity in the root of the firſt ſpecies, which is in its vegetating only every other year, and the intermediate years it remains at reſt.

FICOIDES. See Meſembryanthemum.

FICUS. Lin. Gen. Plant. 1032. Tourn. Inſt. R. H. 662. tab. 420. The Fig-tree; in French, *Figuier*.

The Characters are,

It hath male and female flowers, which are included within the covering, or ſkin of the fruit, ſo do not appear unleſs the covering is opened; the male flowers are but few in number, and are ſituated in the upper part of the fruit; the female flowers are numerous, and ſituated in the lower part.

part. The male flowers ſit each upon a ſeparate foot-ſtalk, and have an empalement divided into three parts; they have no petals, but three briſtly ſtamina as long as the empalement, terminated by twin ſummits; the female flowers ſit upon diſtinct foot-ſtalks; their empalements are divided into five parts; they have no petals, but a germen as the empalement, ſupporting an inflexed ſtyle, crowned by two reflexed pointed ſtigmas. The germen afterward becomes a large ſeed, ſitting in the empalement.

This genus of plants is ranged in the third ſection of Linnæus's twenty-third claſs, intitled Polygamia Polyœcia; the male and hermaphrodite flowers being ſituated in the ſame common covering, but in the wild Fig they are in diſtinct plants.

The Species are,

1. Ficus (*Carica*) foliis palmatis. Hort. Cliff. 471. *Fig-tree with hand-ſhaped leaves.* Ficus communis. C. B. P. 457. *The common Fig-tree.*
2. Ficus (*Sycomorous*) foliis cordatis ſubrotundis integerrimis. Hort. Cliff. 471. *Fig-tree with roundiſh heart-ſhaped leaves, which are entire.* Ficus folio mori, fructum in caudice ferens. C. B. P. 459. *Fig-tree with a Mulberry leaf, bearing fruit on the body or ſtem, commonly called Sycamore.*
3. Ficus (*Religioſa*) foliis cordatis oblongis integerrimis acuminatis. Hort. Cliff. 471. *Fig-tree with entire heart-ſhaped leaves, ending in acute points.* Ficus Malabarienſis, folio cuſpidato, fructu rotundo parvo gemino. Pluk. Alm. 144. *Malabar Fig with a long pointed leaf, and ſmall double round fruit.*
4. Ficus (*Benghalenſis*) foliis ovatis integerrimis obtuſis, caule infernè radicato. Hort. Cliff. 471. *Fig-tree with oval, obtuſe, entire leaves, and the lower part of the ſtalk putting out roots.* Ficus Benghalenſis, folio ſubrotundo, fructu orbiculato. Hort. Amſt. 1. p. 119. *Bengal Fig with a roundiſh leaf, and orbicular fruit.*
5. Ficus (*Indica*) foliis lanceolatis petiolatis, pedunculis aggregatis, ramis radicantibus. Lin. Sp. Plant. 1060. *Fig-tree with ſpear-ſhaped leaves having petals, the foot-ſtalks of the fruit growing in cluſters, and branches ſending out roots.* Ficus Indica Theophraſti. Tabern. Hiſt. 1370. *Indian Fig of Theophraſtus.*
6. Ficus (*Maximus*) foliis lanceolatis integerrimis. Hort. Cliff. 471. *Fig-tree with entire ſpear-ſhaped leaves.* Ficus Indica maxima, folio oblongo, funiculis è ſummis ramis dimiſſis radices agentibus ſe propagans, fructu minori ſphærico ſanguineo. Sloan. Cat. Jam. 189. *The largeſt Indian Fig with an oblong leaf, ſending out roots from the tops of the branches, and a ſmall ſpherical blood-coloured fruit.*
7. Ficus (*Racemoſa*) foliis ovatis acutis integerrimis, caule arboreo, fructu racemoſa. Lin. Sp. Plant. 1060. Amœn. Acad. 1. p. 30. *Fig-tree with oval, entire, acute leaves, tree-like ſtalk, and branching fruit.* Alty-alu. Hort. Mal. 1. p. 43.
8. Ficus (*Pumila*) foliis ovatis acutis integerrimis, caule repente. Lin. Sp. Plant. 1060. Amœn. Acad. 1. p. 30. *Fig-tree with oval, acute, entire leaves, and a creeping ſtalk.* Ficus ſylveſtris procumbens, folio ſimplici. Kœmpf. Amœn. 803. *Trailing wild Fig-tree having ſingle leaves.*
9. Ficus (*Nymphææfolia*) foliis ovato-cordatis integerrimis glabris. *Fig-tree with oval, heart-ſhaped, entire, ſmooth leaves,* vulgarly called Ficus nymphææ folio. *Fig-tree with a Water Lily leaf.*
10. Ficus (*Citrifolia*) foliis oblongo-cordatis acuminatis, petiolis longiſſimis. *Fig-tree with oblong, heart-ſhaped, pointed leaves, and very long foot-ſtalks.* Ficus citrii folio, fructu parvo purpureo. Cateſb. Hiſt. Carol. 3. p. 18. *Fig-tree with a Citron-leaf, and ſmall purple fruit.*
11. Ficus (*Calyculata*) foliis ovatis integerrimis obtuſis, oppoſitis, fructu globoſo calyculato. *Fig-tree with oval, obtuſe, entire leaves placed oppoſite, and a globular fruit having a calyx.* Ficus folio lato ſubrotundo, fructu globoſo, magnitudine nuces moſchatæ. Houſt. MSS. *Fig-tree with broad roundiſh leaves, and a globular fruit about the bigneſs of a nutmeg.*

The firſt ſort, which is the Fig whoſe fruit is valuable, is cultivated in moſt parts of Europe; of this there are great varieties in the warm countries, which have been obtained from ſeeds, therefore may be increaſed annually, if the inhabitants were careful in propagating the trees from the ſeeds of their beſt ſorts. In England we had not more than four or five ſorts till within a few years paſt; for as the generality of the Engliſh were not lovers of this fruit, ſo there were few who troubled themſelves with the culture of it. But ſome years paſt I had a large collection of theſe trees ſent me from Venice, by my honoured friend the Chevalier Rathgeb, which I planted and preſerved to taſte of their fruits, ſeveral of which proved excellent; theſe I have preſerved and propagated, and thoſe whoſe fruit were inferior have been neglected. And as the variety of them is very great, ſo I ſhall here mention only ſuch of them as are the beſt worth cultivating, placing them in the order of their ripening.

1. The brown or Cheſnut-coloured Iſchia Fig. This is the largeſt fruit of any I have yet ſeen, it is ſhort, globular, with a pretty large eye, pinched in near the foot-ſtalk, of a brown or Cheſnut colour on the outſide, and purple within; the grains are large, and the pulp ſweet and high-flavoured; this ſort very often burſts open when it ripens. It ripens the latter end of July, or the beginning of Auguſt. I have had this fruit ripen well on ſtandards, in a warm ſoil. If this ſort is planted againſt hot walls, two plentiful crops of fruit may be annually ripened.
2. The black Genoa Fig. This is a long fruit, which ſwells pretty large at the top where it is obtuſe, but the lower part is very ſlender toward the ſtalk; the ſkin is of a dark purple colour, almoſt black, and hath a purple farina over it like that on ſome Plumbs; the inſide is of a bright red, and the fleſh is very high flavoured. It ripens early in Auguſt.
3. The ſmall white early Fig. This hath a roundiſh fruit a little flatted at the crown, with a very ſhort foot-ſtalk; the ſkin, when fully ripe, is of a pale yellowiſh white colour; the ſkin is thin, the inſide white, and the fleſh ſweet, but not high-flavoured. This ripens in Auguſt.
4. The large white Genoa Fig. This is a large globular fruit, a little lengthened toward the ſtalk; the ſkin is thin, of a yellowiſh colour when fully ripe, and red within. This is a good fruit, but the trees are not good bearers.
5. The black Iſchia Fig. This is a ſhort fruit, of a middling ſize, a little flatted at the crown; the ſkin is almoſt black when ripe, and the inſide is of a deep red; the fleſh is very high flavoured, and the trees produce a good crop of fruit, but the birds are great devourers of them if they are not protected from them. This ripens in Auguſt.
6. The Malta Fig. This is a ſmall brown fruit, much compreſſed at the top, and greatly pinched toward the foot-ſtalk; the ſkin is of a pale brown colour, as is alſo the inſide; the fleſh is very ſweet, and well flavoured. If this ſort is permitted to hang upon the trees till the fruit is ſhrivelled, it becomes a fine ſweetmeat.
7. The Murrey, or brown Naples Fig. This is a pretty large globular fruit, of a light brown colour on the outſide, with ſome faint marks of a dirty white, the inſide is nearly of the ſame colour; the grains are pretty large, and the fleſh is well flavoured. It ripens the latter end of Auguſt.
8. The green Iſchia Fig. This is an oblong fruit, almoſt globular at the crown; the ſkin is thin, of a green colour, but when it is fully ripe, it is ſtained through by the pulp to a browniſh caſt; the inſide is purple, and will ſtain linen, or paper; the fleſh is high flavoured, eſpecially in warm ſeaſons. It ripens toward the end of Auguſt.
9. The Madonna Fig, commonly called here the Brunſwick, or Hanover Fig, is a long pyramidal fruit of a large ſize; the ſkin is brown; the fleſh is of a lighter brown colour, coarſe, and hath little flavour. This ripens the end of Auguſt and the beginning of

September; the leaves of this ſort are much more divided than of moſt other.

10. The common blue, or purple Fig is ſo well known, as to need no deſcription.

11. The long brown Naples Fig. The leaves of this tree are deeply divided. The fruit is long, ſomewhat compreſſed at the crown. The foot-ſtalks are pretty long; the ſkin is of a dark brown when fully ripe, the fleſh inclining to red; the grains are large, and the fleſh well flavoured. It ripens in September.

12. The yellow Iſchia Fig. This is a large fruit, of a pyramidal form; the ſkin is yellow when ripe, and the fleſh is purple and well flavoured, but the trees do not produce much fruit here; they grow very luxuriant in branches, the leaves are very large, and not much divided. This ripens in September.

13. The ſmall Brown Iſchia Fig. This is a ſmall pyramidal fruit with a very ſhort foot-ſtalk; the ſkin is of a light brown, the fleſh inclining to purple, of a very high flavour; it ripens late in September; the leaves of this tree are leſs divided than any of the other ſorts. This is not a good bearer.

14. The Gentile Fig. This is a middle ſized globular fruit; the ſkin, when ripe, is yellow; the fleſh alſo inclines to the ſame colour; the grains are large, and the fleſh is well flavoured, but it ripens very late, and the trees are bad bearers, ſo that it is not propagated much in England.

There are ſeveral other ſorts which have been lately introduced from Italy, but all thoſe which I have yet taſted, are inferior to thoſe above-mentioned; ſome of them rarely ripen their fruit, and others are very ill bearers, not worth propagating, therefore I have omitted the mentioning of them here; for as thoſe which are enumerated, continue in ſucceſſion during the ſeaſon for theſe fruits, and being preferable to the other, few perſons will care to fill their gardens with a greater variety of theſe trees than are of real uſe, eſpecially as they require good walls, and a very large ſhare of room.

The firſt, ſecond, third, ninth, and tenth ſorts will ripen their fruits on ſtandards, where they are in a warm ſituation; but the others require the aſſiſtance of walls expoſed to good aſpects, otherwiſe their fruit will not ripen in England.

Fig-trees generally thrive in all ſoils, and in every ſituation; but they produce a greater quantity of fruit upon a ſtrong loamy ſoil, than on dry ground; for if the ſeaſon proves dry in May and June, thoſe trees which grow upon very warm dry ground, are very ſubject to caſt their fruit; therefore, whenever this happens, ſuch trees ſhould be well watered and mulched, which will prevent the fruit from dropping off; and the fruit upon theſe trees are better flavoured, than any of thoſe which grow upon cold moiſt land. I have always obſerved thoſe Fig-trees to bear the greateſt quantity of well-flavoured fruit, which were growing upon chalky land, where there has been a foot or more of a gentle loamy ſoil on the top. They alſo love a free open air; for although they will ſhoot and thrive very will in cloſe places, yet they ſeldom produce any fruit in ſuch ſituations; and all thoſe which are planted in ſmall gardens in London, will be well furniſhed with leaves, but I have never ſeen any fruit upon them which have grown to maturity.

Theſe trees are always planted as ſtandards in all warm countries, but in England they are generally planted againſt walls, there being but few ſtandard Fig-trees at preſent in the Engliſh gardens; however, ſince ſome of the ſorts are found to ripen their fruit well upon the ſtandards, and the crop of Figs is often greater upon them, than upon thoſe trees againſt walls, it is worthy of our care, to plant them either in ſtandards or eſpaliers; the latter, I think, will ſucceed beſt in England, if they were managed as in Germany, where they untie the Fig-trees from the eſpalier, and lay them down, covering them in winter with ſtraw or litter, which prevents their ſhoots being injured by the froſt; and this covering is taken away gradually in the ſpring, and not wholly removed until all the danger of froſt is over, by which management they generally have a very great crop of Figs; whereas in England, where the trees grow againſt warm walls, if the ſpring proves warm, the young Figs are puſhed out early, and the cold, which frequently returns in April and May, cauſes the greateſt part of the fruit to drop off; ſo that our crop of Figs is generally more uncertain than moſt other ſorts of fruit: and it frequently happens, that trees which are planted againſt north and eaſt-aſpected walls, produce a greater quantity of fruit in England, than thoſe which are planted againſt ſouth and ſouth-eaſt aſpects; which muſt happen from the latter putting out their fruit ſo much earlier in the ſpring than the former; and if there happen cold froſty nights after the Figs are come out (which is frequently the caſe in this country) the forwardeſt of the Figs are generally ſo injured as to drop off from the trees ſoon after. In Italy, and the other warm countries, this firſt crop of Figs is little regarded, being few in number; for it is the ſecond crop of Figs which are produced from the ſhoots of the ſame year, which is their principal crop, but theſe rarely ripen in England; nor are there above three or four ſorts which ever ripen their ſecond crop, let the ſummer prove ever ſo good, therefore it is the firſt crop which we muſt attend to in England; ſo that when theſe trees are growing againſt the beſt aſpected walls, it will be a good method to looſen them from the wall in autumn; and after having diveſted the branches of all the latter fruit, to lay the branches down from the wall, faſtening them together in ſmall bundles, ſo that they may be tied to ſtakes, to keep them from lying upon the ground; the damp whereof, when covered in froſty weather, might cauſe them to grow mouldy, and hereby they will be ſecured from being broken by the wind. When they are thus managed in autumn, if the winter ſhould prove very ſevere, the branches may be eaſily covered with Peas-haulm, ſtraw, or any other light covering, which will guard the tender fruit-bearing branches from the injury of froſt; and when the weather is mild, the covering muſt be removed, otherwiſe the Figs will come out too early; for the intention of this management is, to keep them as backward as poſſible: then in the ſpring, when the Figs are beginning to puſh out, the trees may be faſtened up to the wall again. By this management I have ſeen very great crops of Figs produced in two or three places.

I have alſo ſeen great crops of Figs in ſome particular gardens, after very ſharp winters, when they have, in general, failed in other places, by covering up the trees with Reeds made into pannels, and fixed up againſt the walls.

In the pruning of Fig-trees, the branches muſt never be ſhortened, becauſe the fruit are all produced at the upper part of the ſhoots of the former year; if theſe are cut off, there can be no fruit expected, beſide the branches are very apt to die after the knife; ſo that when the branches are too cloſe together, the beſt way is to cut out all the naked branches quite to the bottom, leaving thoſe which are beſt furniſhed with lateral branches at a proper diſtance from each other, which ſhould not be nearer than a foot; and when they are well furniſhed with lateral branches, if they are laid four or five inches farther aſunder, it will be better.

The beſt ſeaſon for pruning of Fig-trees is in autumn, becauſe at that time the branches are not ſo full of ſap, and will not bleed ſo much, as when they are pruned in the ſpring; and at this ſeaſon, the branches ſhould be diveſted of all the autumnal Figs, and the ſooner this is done, when the leaves begin to fall off, the better will the young ſhoots reſiſt the cold of the winter. There are ſome ſeaſons ſo cold and moiſt, that the young ſhoots of the Fig-trees will not harden, but are ſoft, and full of juice; when this happens, there is little hope of a crop of Figs the ſucceeding year, for the firſt froſt in autumn will kill the upper part of theſe ſhoots, for a conſiderable length downward; whenever this happens, it is the beſt way to cut off all the decayed part of the ſhoots, which will prevent the infection from deſtroying all the lower part of the branches; and, by this method, I have ſeen a moderate crop of Figs put out from the lower part of the ſhoots; where, if the ſhoots had not been injured, there would have been no fruit produced, becauſe it is chiefly from the four or five uppermoſt joints of the ſhoots that the fruit comes out; and it is for this reaſon, that as many of the ſhort lateral branches ſhould be preſerved as poſſible, thoſe being the moſt productive of fruit; for where the long ſtrait ſhoots are faſtened up, there will be no fruit, but at their extremities, ſo that all the lower part of the trees will be naked, if there is not a particular regard had to ſupply young ſhoots in every part of the trees.

Thoſe trees which are laid down from the eſpaliers, ſhould not be faſtened up again till the end of March, for the reaſons before given, and thoſe againſt walls may remain ſome time longer; and when the large ſhoots of theſe are nailed up, if the ſmall lateral branches are thruſt behind theſe, to keep them cloſe to the wall, it will ſecure the young Figs from being injured by the morning froſts; and when this danger is over, they may be brought forward to their natural poſition again: during the ſummer ſeaſon theſe trees will require no other pruning, but to ſtop the ſhoots in the ſpring, where lateral branches are wanting; and as the branches are often blown down by wind, therefore, whenever this happens, they ſhould be immediately faſtened up again, otherwiſe they will be in danger of breaking; for the leaves of theſe trees being very large and ſtiff, the wind has great power on them; ſo that where the branches are not well ſecured, they are frequently torn down.

Thoſe trees which are planted againſt eſpaliers may be protected from the injury of froſt in the ſpring, by placing Reeds on each ſide the eſpalier, which may be taken down every day, and put up again at night; but this need not be practiſed in warm weather, but only at ſuch times as there are cold winds and froſty mornings; and although there is ſome trouble and expence attending this management, yet the plentiful crop of Figs which may this way be obtained, will ſufficiently recompenſe for both: the beſt way of making this covering is, to faſten the Reeds with rope yarn in ſuch a manner as that it may be rolled up like a mat, that the whole may with great facility be put up or taken down; and if theſe Reeds are carefully rolled up, after the ſeaſon for uſing them is over, and put up in a dry ſhed, they will laſt ſeveral years.

There are ſeveral perſons who of late have planted Fig-trees in ſtandards, which have ſucceeded very well; this practice was revived, by obſerving ſome old ſtandard Fig-trees in ſome gardens, which had been growing many years, and generally produced a much greater plenty of fruit than any of thoſe trees which were growing againſt warm walls; indeed, theſe ſtandard Fig-trees are in much greater danger of having their branches killed by ſevere froſt, but in mild winters they generally do better than thoſe againſt walls; ſo that where theſe trees can be covered in very hard winters, there will always be plenty of fruit; and theſe may be covered by faſtening as many of the branches together as can be conveniently brought into a bundle, and winding ſome Hay-bands, Straw, Peas-haulm, or any ſuch light covering as can be readily procured, which in the ſpring may be gradually taken off, ſo as not to expoſe the ſhoots all at once to the open air; and if there is ſome ſuch light covering laid round the ſtems, and upon the ſurface of the ground about their roots, it will more effectually ſecure them from the danger of froſt; but when this is practiſed, great care ſhould be taken that no mice or rats harbour in this covering, for theſe will eat off the bark from their ſhoots, and kill them: and I have often obſerved thoſe trees which were againſt walls, have ſuffered greatly by theſe vermin, by having many of their largeſt branches diſbarked near the ground, which has abſolutely killed them; and it is in the winter that theſe vermin do this miſchief to them, therefore they ſhould be carefully watched at that ſeaſon.

The common blue and white Figs, which are the ſorts which have been the moſt generally cultivated in England, are not ſo proper to plant for ſtandards, as ſome other ſorts which have been lately introduced; for they are much tenderer, and are often killed almoſt to the root, when ſome of the other ſorts, which have been growing in the ſame ſituation, have received very little injury from the froſt; indeed the white ſort is generally a great bearer, and the fruit is very ſweet; but to thoſe palates which are accuſtomed to Figs, that ſort is not much in eſteem, from its want of flavour: thoſe which have ſucceeded beſt with me, are the firſt and third ſorts. Their branches are rarely hurt by froſt in winter, and their fruit will always ripen well; for in favourable ſeaſons, many of theſe ſorts, which were growing againſt walls, have ripened their ſecond crop of fruit tolerably well. I have alſo planted many of theſe ſorts of Fig-trees againſt north-eaſt and north-weſt aſpects; ſome of thoſe which were firſt planted, have produced a good quantity of well taſted fruit, but were ripe much later, which has encouraged me to plant many more of theſe trees to the ſame aſpects, and alſo to increaſe my number of ſtandard trees.

I am aware, that what I have here advanced, in relation to the pruning and dreſſing of Fig-trees, will be condemned by great numbers of people, who will not give themſelves time to conſider and examine the reaſons upon which I have founded this practice, nor to make one ſingle experiment to try the truth of it, as being vaſtly different from the general practice of moſt gardeners, who always imagine, that Fig-trees ſhould never have much pruning; or, at leaſt, that they ſhould always be ſuffered to grow very rude from the wall, to ſome diſtance. That by this management I have often ſeen great quantities of fruit I cannot deny, but then this has been only after mild winters; for it is very certain, that in ſharp froſts few of theſe outſide ſhoots eſcape being greatly injured where they are not covered; whereas it rarely happens that thoſe ſhoots which are cloſely nailed to the wall in autumn, or laid down and covered, ſuffer the leaſt damage; and the fruits are always produced a fortnight ſooner upon theſe branches, than they are upon thoſe which grow from the wall: but although the trees which are ſuffered to grow rude from the walls may produce a good quantity of fruit for a year or two, yet afterward the trees will only bear at the ends of the ſhoots, which will then be ſo far from the wall, as to receive little benefit from it; nor can the trees be reduced again to any regularity, without cutting away the greateſt number of their branches, by which a year or two will be loſt before they will come to bear again.

The ſeaſon alſo for pruning, which I have laid down, being vaſtly different from the common practice and opinion of moſt gardeners, will alſo be objected againſt; but I am ſure, if any one will but make trial of it, I doubt not his experience will confirm what I have here advanced; for as one great injury to this tree proceeds from the too great effuſion of ſap at the wounded parts, by this autumn pruning this is prevented; for, at that ſeaſon, all the parts of European trees which caſt their leaves, are leſs replete with moiſture than at any other time of the year; for by the long continuance of the ſummer's heat, the juices of plants having been exhauſted in the nouriſhment and augmentation of wood, leaves, fruits, &c. and alſo great quantities being evaporated by perſpiration, the root not being able to ſend up a ſupply equivalent to this great conſumption, the branches muſt contain a much leſs quantity of ſap than in the ſpring, when it has had ſeveral months ſupply from the root; which, though but ſmall in proportion to what is ſent up when the heat is greater, yet there being little or no waſte, either by perſpiration or augmentation, there muſt be a greater quantity contained in the branches; which alſo is eaſily to be obſerved, by breaking or cutting off a vigorous branch of a Fig-tree at both ſeaſons (the ſap, being milky, may be readily diſcerned) when that cut in autumn ſhall be found to ſtop its bleeding in one day's time, or leſs; whereas that cut in the ſpring will often flow a week or more, and the wound will be proportionably longer before it heals.

Of late years there has been ſome of theſe trees planted againſt fire-walls, which have ſucceeded very well where they have been properly managed; but where they have been kept too cloſe, and drawn by glaſſes, they have not produced much fruit; therefore whenever this is practiſed, the heat ſhould not be too great, nor the glaſſes, or other covering, kept too cloſe, but at all times, when the weather is favourable, a good ſhare of free air ſhould be admitted; and if the trees are young, that their roots are not extended beyond the reach of the covering, they muſt be frequently watered when they begin to ſhew fruit, otherwiſe it will drop off; but old trees, whoſe roots are extended to a great diſtance, will only require to have their branches now and then ſprinkled over with water. If theſe trees are properly managed, the firſt crop of fruit will be greater than upon thoſe which are expoſed to the open air, and will ripen ſix weeks or two months earlier, and a plentiful ſecond crop may alſo be obtained, which will ripen early in September, and ſometimes in Auguſt, which is about the ſeaſon of their ripening in the warmer parts of Europe; but the fires ſhould not be uſed to theſe trees till the beginning of February; becauſe when they are forced too early, the weather is frequently too cold to admit a ſufficient quantity of freſh air to ſet the fruit; but the covers ſhould be put over the trees a month before, to prevent the ſhoots from being injured by the froſt.

It may not be improper in this place to mention the great pains which the inhabitants of the Levant are at in the culture of their Figs; and without which (it is generally ſaid by all the travellers who have written on this ſubject, as alſo by Pliny, and other old naturaliſts) their fruit will fall off, and be good for nothing. I ſhall here ſet it down, as I find it in the travels of Monſ. Tournefort, chief botaniſt to the late king of France.

“Pliny, ſays he, obſerved, That in Zia they uſed to dreſs the Fig-trees with much care; they ſtill continue to do ſo. To underſtand aright this huſbandry of Figs (called in Latin, Caprificatio) we are to obſerve, that in moſt of the iſlands of the Archipelago, they have two ſorts of Fig-trees to manage; the firſt is called Ornos, from the old Greek, Erinos, a wild Fig-tree; or Caprificus, in Latin; the ſecond is the domeſtic, or garden Fig-tree; the wild ſort bears three kinds of fruit, Fornites, Cratitires, and Orni, of abſolute neceſſity towards ripening thoſe of the garden Fig.

“The Fornites appear in Auguſt, and continue to November, without ripening; in theſe breed ſmall worms, which turn to a ſort of gnats, no where to be ſeen but about theſe trees. In October and November theſe gnats of themſelves make a puncture into the ſecond fruit, which is called Cratitires, and do not ſhew themſelves till towards the end of September; and the Fornites gradually fall away after the gnats are gone; the Cratitires, on the contrary, remain on the tree till May, and incloſe the eggs, depoſited by the Fornites, when they pricked them. In May the third ſort of fruit begins to put forth from the ſame wild Fig-trees which produced the other two; this is much bigger, and is called Orni; when it grows to a certain ſize, and its bud begins to open, it is pricked in that part by the gnats of the Cratitires, which are ſtrong enough to go from one fruit to the other, to diſcharge their eggs.

“It ſometimes happens, that the gnats of the Cratitires are ſlow to come forth in certain parts, while the Orni in thoſe very parts are diſpoſed to receive them; in which caſe the huſbandman is obliged to look for the Cratitires in another part, and fix them at the end of the branches of thoſe Fig-trees, whoſe Orni are in fit diſpoſition to be pricked by the gnats; if they miſs the opportunity the Orni fall, and the gnats of the Cratitires fly away. None but thoſe that are well acquainted with this ſort of culture, know the critical minutes of doing this; and in order to it, their eye is perpetually fixed on the bud of the Fig; for that part not only indicates the time that the prickers are to iſſue forth, but alſo when the Fig is to be ſucceſsfully pricked; if the bud be too hard, and too compact, the gnat cannot lay its eggs, and the Fig drops when this bud is too open.

“Theſe three ſorts of fruit are not good to eat; their office is to help to ripen the fruit of the garden Fig-trees, in manner following: during the months of June and July, the peaſants take the Orni at a time that their gnats are ready to break out, and carry them to the garden Fig-trees; if they do not nick the moment, the Orni fall, and the fruit of the domeſtic or garden Fig-tree not ripening, will, in a very little time, fall in like manner. The peaſants are ſo well acquainted with theſe precious moments, that every morning, in making their inſpection, they only transfer to their garden Fig-trees ſuch Orni as are well conditioned, otherwiſe they loſe their crop. It is true, they have one remedy, though an indifferent one, which is, to ſtrew over the garden Fig-trees the Aſcolimbros, a very common plant there, and in whoſe fruit there is a ſort of gnats proper for pricking; perhaps they are the gnats of the Orni, which are uſed to hover about and plunder the flowers of this plant.

“To ſum up all in one word, The peaſants ſo well order the Orni, that their gnats cauſe the fruit of the garden Fig-tree to ripen in the compaſs of forty days. Theſe Figs are very good green; when they would dry them, they lay them in the ſun for ſome time, then put them in an oven to keep them the reſt of the year. Barley bread and dried figs are the principal ſubſiſtence of the boors and monks of the Archipelago; but theſe Figs are very far from being ſo good as thoſe dried in Provence, Italy, and Spain; the heat of the oven deſtroys all their delicacy and good taſte; but then, on the other hand, this heat kills the eggs which the prickers of the Orni diſcharged therein, which eggs would infallibly produce ſmall worms that would prejudice theſe fruits.

“What an expence of time and pains is here for a Fig, and that but an indifferent one at laſt! I could not ſufficiently admire the patience of the Greeks, buſied above two months in carrying theſe prickers from one tree to another. I was ſoon told the reaſon, one of their Fig-trees uſually produces between two and three hundred pounds of Figs, and ours in Provence ſeldom above twenty-five.

“The prickers contribute, perhaps, to the maturity of the fruit of the garden Fig-tree, by cauſing them to extravaſate the nutritious juice, whoſe veſſels they tear aſunder in depoſiting their eggs; perhaps too, beſides their eggs, they leave behind them ſome ſort of liquor proper to ferment gently with the milk of the Fig, and to make their fleſh tender. Our Figs in Provence, and even at Paris, ripen much ſooner for having their buds pricked with a Straw dipped in olive oil. Plumbs and Pears, pricked by ſome inſects likewiſe ripen much the faſter for it; and the fleſh round ſuch puncture is better taſted than the reſt. It is not to be diſputed but that conſiderable change happens to the contexture of fruits ſo pricked, juſt the ſame as to parts of animals pierced with any ſharp inſtrument.

“It is ſcarce poſſible well to underſtand the antient authors who have treated of caprification (or huſbanding and dreſſing the wild Fig-tree) if one is not well appriſed of the circumſtances, the particulars whereof were confirmed to us not only at Zia, Tinos, Mycone, and Scio, but in moſt of the other iſlands.”

Fig-trees are propagated in England, either by the ſuckers, which are ſent out from their roots, and by layers made, by laying down of their branches, which in one year will put out roots ſufficient to be removed, or by planting of cuttings, which, if properly managed, will take root; the firſt of theſe is a bad method, becauſe all thoſe trees which are raiſed from ſuckers, are very ſubject to ſend out great quantities of ſuckers again from their roots; and the branches of the ſuckers are not ſo compact, as thoſe of the layers, but are fuller of ſap, ſo in greater danger of being injured by the froſt; thoſe plants which are propagated by layers, are the beſt, provided the layers are made from the branches of fruitful trees; for thoſe which are made from the ſuckers, or ſhoots, produced from old ſtools, are very ſoft, and full of ſap, ſo are in danger of ſuffering by the froſt, and theſe will ſhoot greatly into wood, but will not be very fruitful; for, when trees have acquired a vicious habit while young, it is ſeldom they are ever brought to be fruitful afterward; therefore the ſhoots which are laid down, ſhould be ſuch as are woody, compact, and well ripened, not young ſhoots, full of ſap, whoſe veſſels are large and open. The beſt time for laying down of the branches is in autumn; and if the winter ſhould prove very ſevere, if they are covered with ſome old tan, or any other mulch, to keep the froſt from penetrating the ground, it will be of great ſervice to them; by the autumn following, theſe will be ſufficiently rooted for removing, when they ſhould be cut off from the old plants, becauſe at that ſeaſon the branches are not ſo full of ſap as in the ſpring, ſo will not bleed ſo much as when cut off in the ſpring. If the place is ready to receive them, the layers ſhould be tranſplanted in autumn, where they are to remain; but if it is not, then the layers may remain till the ſpring, provided they are ſeparated from the old plants in autumn. As theſe plants do not bear tranſplanting well when they are large, it is the better way to plant them at firſt in places where they are to remain; and after they are planted, the ſurface of the ground about their roots ſhould be covered with mulch to keep out the froſt; and if the winter ſhould prove very ſevere, it will be proper to cover the branches with Reeds, Peas-haulm, Straw, or ſome other light covering, which will prevent their tender ends being killed by the froſt, which frequently happens where this care is wanting.

The other method of propagating theſe trees, is by cuttings, which ſhould be taken from the trees in autumn, for the reaſon before given: theſe muſt be choſen from ſuch branches as are compact, whoſe joints are near each other; and they ſhould have a part of the former year's wood at their bottom, and the top of each ſhould be left entire, not ſhortened as is uſually practiſed with other cuttings; then they ſhould be planted eight or nine inches deep, in a bed of loamy earth, in a warm ſituation, covering the ſurface of the ground, three or four inches thick, with old tanner's bark, to keep out the froſt; and in ſevere froſt their tops ſhould be covered with Straw, Peas-haulm, Fern, or other light covering, to protect them from froſt, which ſhould be removed in the ſpring; but the tan may remain, for that will prevent the drying winds of the ſpring, and the ſun in ſummer, from penetrating the ground, and will be of great uſe to ſecure the cuttings from injury; theſe cuttings will be rooted ſufficiently by the following autumn, when they ſhould be tranſplanted, and treated in the ſame manner as the layers.

If fruitful branches of theſe trees are cut off, and planted in pots, or tubs, filled with good earth, and theſe are plunged into a good hot-bed of tanners bark in the ſtove, they will put out fruit early in the ſpring, which will ripen in the middle of May.

We ſhall now return to the other ſorts of Figs, which grow naturally in warm countries, but are preſerved in the gardens of thoſe who are curious in collecting rare exotic plants, for theſe do not bear eatable fruit in their native ſoil; but their leaves being large and beautiful, the plants make a pleaſing variety in the ſtove.

The ſecond ſort grows naturally in the Levant, where it becomes a large tree, dividing into many branches, which are garniſhed with leaves ſhaped like thoſe of the Mulberry, and affords a friendly ſhade in thoſe hot countries. The fruit is produced from the trunk and larger branches of the tree, and not on the ſmaller ſhoots, as in moſt other trees; the ſhape is like the common Fig, but is little eſteemed. This is called the Sycamore, or Pharaoh's Fig-tree.

The third ſort grows naturally in India, where it is ſacred, ſo that none dare deſtroy them; it is called by ſome the Indian God-tree; this riſes with a woody ſtem to a great height, ſending out many ſlender branches, which are garniſhed with ſmooth heart-ſhaped leaves, ending in a long tail, or point; they are entire, ſmooth, and of a light green, having pretty long foot-ſtalks; they are between ſix and ſeven inches long, and three inches and a half broad toward their baſe, diminiſhing gradually to the top, where they run out in a narrow point, an inch and a half long. The fruit comes out on the branches, which are ſmall, round, and of no value.

The fourth ſort riſes with many ſtalks, which grow to the height of thirty or forty feet, dividing into a great number of branches, which ſend out roots from their under branches, many of which reach to the ground; ſo that in ſuch places where the trees grow naturally, their roots and branches are ſo interwoven with each other, as to render the places impaſſable. In India, the Banyans trail the branches of theſe trees into regular archades, and ſet up their pagods under them, theſe being the places of their devotion. In America, where theſe trees are equally plenty, they form ſuch thickets, as neither man nor beaſt can paſs through. The leaves of this ſort are of a thick ſubſtance, ſmooth, and oval; they are ſix inches long, and four inches broad, with obtuſe ends. The fruit is the ſize of a marble, and round, but of no uſe.

The fifth ſort grows naturally in both Indies; this riſes with a woody ſtalk to the height of thirty feet, ſending out many branches, which are garniſhed with oblong leaves ſtanding upon pretty long foot-ſtalks; they are about ſix or eight inches long, and two inches and a half broad, ending in an obtuſe point, of a dark green, and ſmooth on their upper ſide, but of a light green, and veined on their under ſide. The fruit is ſmall, and of no value. The branches of theſe trees ſend out roots from their lower ſide, which ſometimes reach the ground.

The ſixth ſort grows naturally in the Weſt-Indies, where it riſes to the height of thirty or forty feet, ſending ont many ſlender branches, which put out roots in the ſame manner as the former. The leaves of this are eight or nine inches long, and two inches broad, ending in points. The fruit is ſmall, round, and of a blood colour when ripe, but is not eatable.

The ſeventh ſort grows naturally in India, where it riſes to the height of twenty-five feet, and divides into many branches, which are garniſhed with oval-pointed leaves, which are ſmooth, and of a lucid green. The fruit is ſmall, and grows in cluſters from the ſide of the branches; theſe are not eatable.

The eighth ſort grows naturally in India; this is a low trailing ſhrub, whoſe ſtalks put out roots at their joints, which ſtrike into the ground, ſo is propagated plentifully where it naturally grows. The leaves are two inches and a half long, and near two inches broad, ending in points; they are of a lucid green, and are placed without order on the branches; the fruit is ſmall, and not eatable.

The ninth ſort riſes with a ſtrong, upright, woody ſtalk twenty feet high, ſending out ſeveral ſide branches, which are garniſhed with large, oval, ſtiff leaves, about fourteen inches long, and near a foot broad, and are rounded at the ends; they have ſeveral tranſverſe veins, which run from the midrib to the ſides. The foot-ſtalks are long, and frequently turned next to the branches; the upper ſide of the leaves are of a lucid green, and the under ſide is of a gray, or ſea-green colour, they are of a thick ſubſtance, and very ſmooth; this grows naturally in India, from whence it was brought to the gardens in Holland.

The tenth ſort grows naturally in the Weſt-Indies, where it riſes twenty feet high, ſending out many ſide branches, which are covered with a white bark, and garniſhed with oblong heart-ſhaped leaves, ending in acute points; they are about three inches long, and one inch and a half broad, near the baſe; of a lucid green on their upper ſide, but of a pale green on their under, ſtanding upon very long foot-ſtalks. The fruit comes out from the ſide of the branches, toward their ends; they are about the ſize of large gray Peas, and of a deep purple colour, ſitting cloſe to the branches; theſe are not eatable.

The eleventh ſort grows naturally at La Vera Cruz, from whence it was ſent me by the late Dr. Houſtoun; this riſes with many ſhrubby ſtalks to the height of twelve or fourteen feet, and divides into many ſmaller branches, which are garniſhed with oval ſtiff leaves, which are obtuſe; they are four inches long, and three broad, of a light green, and ſtand upon very ſhort foot-ſtalks, which are joined to a cup, in which the fruit ſits; this is globular, and the ſize of a middling nutmeg, of a deep yellow, when ripe, but is not eatable.

The ſecond ſort, I believe, is not in England at preſent; I raiſed two or three of theſe plants from ſeeds in the year 1736, which were deſtroyed by the ſevere froſt in 1740, ſince which time I have not been able to procure any of the ſeeds. The other ſorts are preſerved in ſeveral curious gardens; they are eaſily propagated by cuttings during the ſummer ſeaſon. When the cuttings are taken from the plants, they ſhould be laid in a dry ſhady place for two or three days, that the wounds may be healed over, otherwiſe they are apt to rot; for all theſe plants abound with a milky juice, which flows out whenever they are wounded; for which reaſon, the cuttings ſhould have their wounded part healed over and hardened before they are planted; after which they ſhould be planted in pots filled with ſandy light earth, and plunged into a moderate hotbed, where they ſhould be ſhaded from the ſun, and two or three times a week gently refreſhed with water, if the ſeaſon is warm; but they muſt not have too much moiſture, for that will infallibly deſtroy them. When the cuttings have taken root ſufficient to tranſplant, they ſhould be each planted into a ſeparate ſmall pot filled with light undunged earth, and plunged into the hot-bed again, being careful to ſhade them until they have taken freſh root; then they ſhould have a large ſhare of free air admitted to them at all times when the weather is favourable, to prevent their drawing up weak, and to give them ſtrength before the cold comes on. In autumn the pots ſhould be removed into the ſtove, and plunged into the tan-bed, where they ſhould conſtantly remain, and muſt be treated in the ſame manner as other tender plants from the ſame countries; for although two or three of the ſorts may be treated in a hardier manner, yet they will not make much progreſs.

FICUS INDICA. See Opuntia.

FILAGO. There are ſeveral ſpecies of this genus, ſome of which grow naturally upon barren land in moſt parts of England. They are called by ſome Cottonweed, by others Cudweed, their leaves being white, and, when broken, have cottony threads. Theſe have been ranged under the genus of Gnaphalium by moſt botaniſts, and one of the ſpecies which is uſed in medicine, ſtands in the liſt of ſimples by that appellation. As theſe plants are not cultivated in gardens, I ſhall not trouble the reader with a farther account of them.

FILBERT. See Corylus.

FILIPENDULA. See Spiræa.

FILIUS ANTE PATREM [i. e. the ſon before the father] an expreſſion which botaniſts apply to plants, whoſe flower comes out before their leaves; or thoſe plants which ſend forth ſide branches of flowers, which advance above the middle.

FILIX, Fern. There are great varieties of this plant in the different parts of the world, but particularly in America, as may be ſeen in the Natural Hiſtory of Jamaica, publiſhed by Sir Hans Sloane, Bart. and in Plumier's American Ferns: but as they are plants which are ſeldom propagated in gardens, I ſhall paſs them over in this place.

FILM, that woody ſkin which ſeparates the ſeeds in the pods of plants.

FIMBRIATED [of Fimbria, *Lat.* a fringe] a term relating to the leaves of plants when they are jagged on the edges, having, as it were, a fringe about them; theſe are often called furbelowed leaves.

FIRE. However foreign, at the firſt view, this article may ſeem to our preſent purpoſe, yet I am of opinion, that a tolerable acquaintance with its nature, as far as it can be attained, and its effects, will contribute no ſmall aſſiſtance in forwarding the work of vegetation. And though the theory of fire is indeed philoſophical, yet the conſideration of its effects, and how it operates on vegetables, will be of no ſmall uſe in the culture of them.

That which beſt defines and diſtinguiſhes fire from every thing elſe, is its heating; and ſo it may be defined, Whatſoever warms or heats bodies.

Heat is ſomething, the preſence of which is beſt perceived by the dilatation of the air or ſpirit in the thermometer. So then, fire is a body, and a body in motion too. The motion of it is proved by its expanding the air, and that it is a body by experiment.

Pure mercury, being incloſed in a phial with a long neck, and kept in a gentle heat for the ſpace of a year, will be reduced into a ſolid, and the weight alſo will be increaſed conſiderably; which increaſe cannot proceed from any thing elſe but the acceſſion of fire.

The nature of fire is ſo obſcure and wonderful, that it was held by many of the ancients as a deity; and ſeveral authors of prime note have taken great pains to diſcover the myſtery of it, without having been able to explain many of the principal effects thereof. The learned Herman Boerhaave has uſed no leſs induſtry in making a new ſet of experiments, in order to come to a clearer knowledge of them; and having laid down a new doctrine of fire, in a courſe of public lectures, I ſhall briefly take notice of ſuch of them as I apprehend may be of uſe.

> "Fire (ſays he) in effect, appears to be the general inſtrument of all the motion in the univerſe. The conſtant tenor of a great number of experiments leaves no room to doubt, but that, if there were no fire, all things would inſtantly become fixed and immoveable. Of this there are inſtances every winter; for while froſt prevails, the water, which before was fluid, by a mere privation of heat, becomes ſolid, i. e. hardens into ice, and ſo remains till diſſolved again by fire. Thus, were a man entirely deſtitute of heat, he would immediately freeze into a ſtatue; and thus the air itſelf, which is found in continual motion, being always either expanding or condenſing, would, upon the abſence of fire, contract itſelf, and cohere into a firm rigid maſs; ſo alſo animals and vegetables, all oils, ſalts, &c. would, upon the like occaſion, immediately congeal."

Although this doctrine of fire, here laid down by Boerhaave, ſeems new and extraordinary, at leaſt to thoſe who have been uſed to conſider fire in the light that it has been ſet in by the Lord Bacon, Mr. Boyle, and Sir Iſaac Newton; and though we ought to pay great veneration to thoſe illuſtrious authors, yet, in the judgment of themſelves, we ſhould be in excuſable, if we ſhould abſolutely acquieſce in what they have done, and ſhut the door againſt farther and better information.

It may reaſonably be ſuppoſed, that Dr. Boerhaave has had an opportunity of going beyond them; in that, beſides all the experiments and obſervations that they have had to build upon, he has had the advantage of a new ſet, which they were unacquainted with.

As to the nature of fire, the great and fundamental difference is, whether it be originally ſuch, formed thus by the great Creator himſelf, at the beginning of things? or, whether it be mechanically producible from other bodies, by inducing ſome alteration in the particles of it?

Among the modern writers, Homberg, Boerhaave, the younger Lemery, and Dr. Graveſande, maintain the former, and the Engliſh authors chiefly maintain the latter.

Monſ. Homberg holds, That the chymical principle or element, ſulphur, which is ſuppoſed one of the ſimple, primary, pre-exiſtent ingredients of all natural bodies, is real fire; and, of conſequence, fire is coeval with all bodies. Eſſai de Souffre Principe, Mem. de l'Academie, anno 1705.

Dr. Graveſande proceeds much on the ſame principle: according to him, fire enters the compoſition of all bodies, is contained in all bodies, and may be ſeparated or procured from all bodies, by rubbing them againſt each other, and thus putting their fire in motion: and he adds, That fire is by no means generated by ſuch motion. Elem. Phyſ. Tom. II. cap. 1.

Mr. Lemery the younger, aſſerts the abſolute and ingenerable nature of fire, and alſo extends it farther; not contented to confine it, as an element, to bodies, he endeavours to ſhew, that it is "Equably diffuſed through all ſpace; is preſent in all places; in the void ſpace between bodies, as well as the inſenſible interſtices between their parts." Mem. de l'Acad. anno 1713.

This laſt ſentiment falls in with that of Boerhaave.

Of the contrary opinion is the Lord Bacon, who, in his treatiſe de Forma Calidi, deduces from a great number of particulars, that heat in bodies is no other than motion, only a motion ſo and ſo circumſtantiated; ſo that to produce heat in a body, nothing is required but to excite ſuch motion in the parts of it.

His opinion is ſeconded by Mr. Boyle, in his treatiſe of the Mechanical Origin of Heat and Cold; where he maintains the ſame doctrine, with new obſervations and experiments, of which two are as follow:

He ſays, "In the production of heat there appears nothing on the part either of the agent or patient but motion, and its natural effects. When a ſmith briſkly hammers a ſmall piece of iron, the metal thereby becomes exceedingly hot; yet there is nothing to make it ſo, except the forcible motion of the hammer, impreſſing a vehement and variouſly determined agitation on the ſmall parts of the iron; which, being a cold body before, becomes by that ſuperinduced commotion of its ſmall parts hot; firſt, in a more looſe acceptation of the word, with regard to ſome other bodies, compared with which it was cold before; then ſenſibly hot, becauſe this agitation ſenſibly ſurpaſſes that of the parts of our fingers. And in this inſtance oftentimes the hammer and anvil continue cold after the operation; which ſhews, that the heat acquired by the iron was not communicated by either of theſe implements, as heat, but produced in it, by a motion great enough ſtrongly to agitate the parts of ſo ſmall a body as the piece of iron, without being able to have the like effect upon ſo much greater maſſes of metal as the hammer and anvil; though if the percuſſions were often and briſkly renewed, and the hammer were ſmall, this alſo might be heated; whence it is not neceſſary, that a body itſelf ſhould be hot to give heat.

"If a large nail be driven by a hammer into a plank of wood, it will receive ſeveral ſtrokes on its head, ere it grows hot; but when it is once driven to the head, a few ſtrokes ſuffice to give it a conſiderable heat; for while at every blow with the hammer the nail enters farther into the wood, the motion produced is chiefly progreſſive, and is of the whole nail tending one way; but, when the motion ceaſes, the impulſe given by the ſtroke being unable to drive the nail farther on or break it, muſt be ſpent in making a various, vehement, and inteſtine commotion of the parts among themſelves, wherein the nature of heat conſiſts."

That fire is the real cauſe of all the changes in nature, will appear from the following conſideration.

All bodies are either ſolid or fluid; the ſolid of themſelves are either commonly ſuppoſed to be inactive or motionleſs; the fluid both move and are moved.

And all ſolids are found to be ſo much the more firm and contracted, as they have the leſs fire in them. This is evident in iron, which, when heated, expands itſelf into a much greater ſpace than when it was cold; ſo that any ſolid and hard body, by being freed from all fire, would ſink into a much leſs bulk, and its parts would cohere more nearly, and with greater force than before.

As to fluids, they all harden, ſo as to be viſible to the eye upon the abſence of fire; as water, by the cold of a ſevere winter, will form itſelf into a ſolid globe, and yet even then contains a great deal of fire, as appears evidently upon applying a thermometer to it, which is capable of falling twenty diviſions lower before it arrive at the point of the moſt intenſe cold: and hence it is, that the ſpirit of wine is kept from freezing in the thermometer, which would undergo the common fate of other things, were there not abundantly more fire in it.

The air itſelf expands by a greater quantity of fire, and condenſes by a leſs; but it ſtill contains a large quantity of fire, where it is moſt of all contracted; this is evident from the ſtriking of a flint againſt a ſteel, which is followed by ſparks of fire.

Likewiſe if this fire could be taken from the air, it would become ſolid and perfectly at reſt, and, by conſequence, uncapable of change.

"Fire (ſays Dr. Graveſande, in Element. Phyſ.) naturally unites itſelf with bodies; and hence it is, that a body brought near to the fire grows hot, in which caſe it alſo expands or ſwells; which expanſion is not only obſerved in very ſolid bodies, but in thoſe whoſe parts do not cohere; in which caſe they likewiſe acquire a great degree of elaſticity, as is obſerved in air and vapours."

Fire being thus acknowledged the inſtrumental cauſe of all motion, it remains that itſelf be moved; nay, to move, muſt be more natural and immediate to fire, than to any other body; and hence ſome have ventured to make motion eſſential to fire: but as this is inconſiſtent with the notion of matter, which is defined to be inert and paſſive, and as fire is capable of being proved material, we ought rather to agree, that the motion of fire itſelf is derived from ſome higher and metaphyſical cauſe. A property of perpetual mobility may indeed be ſuperadded to the other properties of fire, but it has no natural neceſſary connexion with them; nor can it be maintained with them otherwiſe than by ſome extrinſic efficacy of a ſuperior cauſe.

However, that it is by motion that fire produces its effects, is evident; and hence the action of fire cannot make any alteration in the elementary ſubſtance of bodies; for it is neceſſary, that what acts upon an object, be without that object, i. e. the fire muſt not penetrate the elementary parts, but only enter the pores and interſtices of bodies; ſo that it does not ſeem capable of making thoſe tranſmutations, which Sir Iſaac Newton aſcribes to it.

In effect, as to all our purpoſes, it may perhaps be ſaid, that fire is always in motion. For inſtance, take ſix ſeveral ſorts of thermometers, and two veſſels of water with ſal armoniac mixed therein, and apply the thermometers to it; and the conſequence will be, that the air being condenſed in them, the ſpirit will deſcend in all of them: remove the veſſels of water, and the air growing warmer, and rarefying, the ſpirit will aſcend again; ſo that the active force in air, which produces ſo many effects, does really all ariſe from the fire contained in it.

Again: As all bodies placed in a very ſolid air, do, by degrees, grow cold, motionleſs, rigid, &c. i. e. though there be ſtill ſome remains of fire, and in proportion as that is diminiſhed, the effect is accelerated; it follows, that cold, a leſs degree of heat, is the effect of a leſſer action of fire: and all action riſes apparently from the ſame ſource.

Then, as fire can render the moſt ſolid bodies, as ſtone, metals, &c. (as appears very evident in large burning-glaſſes, in which gold itſelf immediately calcines, and emits fumes, i. e. becomes fluid) ſo the want of fire would convert the moſt fluid bodies, as ſpirits of wine, &c. into ſolids.

Fire is diſtinguiſhed into two kinds, called elementary or pure fire, which is ſuch as exiſts in itſelf, and alone is properly called fire; or common or culinary fire, which is raiſed and kindled from the former, and is that which agitates and affects ignited, combuſtible, and moveable bodies, the particles of which, joining with thoſe of the pure fire, conſtitute pure flame.

This latter is improperly called fire, in that not only a ſmall part of it is real or pure fire; and in ignited bodies, that which flames, ſmokes, &c. is not ſimply fire; whereas pure fire, ſuch as is collected in a burning-glaſs, yields no flame, ſmoke, aſhes, or the like.

Fire may be preſent in the greateſt abundance, yet without any heat: this is evident in the tops of the higheſt mountains, illuminated by the ſun, where the cold is always extremely pinching, and this even under the equator, there being mountains there which are perpetually covered with ſnow, though there can be no want of fire.

So a large burning-glaſs has no effect: the ſmalleſt warmth cannot be felt in its focus in a place where the ſun does not ſhine, or when the ſun is covered with a cloud, but a piece of metal may be ſeen to melt the very moment the ſun emerges.

Fire may be in exceeding ſmall quantity, and yet burn with great violence: thus ſpirit of wine when ſet on fire, does not burn the hands; and though poured on a piece of red-hot iron, does not take fire; ſo that the fire that is in, ſhould not appear very great: yet if it meet with ſome harder body while it is burning, the particles of which body it is capable to agitate by the attrition of its own, it will yield a fierce flame, capable of burning a harder body than the hand.

From this it appears, that the relation of heterogeneous particles, agitated by the fire, has more effect in reſpect to heat than the action of the fire itſelf: nor need we be far to ſeek for the mechanical reaſon of this, for the particles of fire, being all equal and ſpherical, muſt of themſelves be harmleſs; but if they carry certain ſpicula, or any other bodies along with them, then they become capable of doing much harm.

Hence, though the flame of a piece of wood may give a ſenſe of heat, and burn ſuch things as are applied to it, it does not therefore neceſſarily follow, that there is any pure fire in it, ſo that the diſtinction of pure and common fire is abſolutely neceſſary: though this diſtinction has been overlooked by moſt or all the authors before Dr. Boerhaave, who have written on fire; which has led them into egregious miſtakes, inſomuch that moſt of them have held, that the flame of a piece of wood is all fire, which appears to be falſe from what has been already ſaid, and alſo what follows.

Elementary or pure fire is of itſelf imperceptible, and only diſcovers itſelf by certain effects that it produces in bodies, and theſe effects are only to be learnt by the changes which ariſe in bodies. Theſe effects are three; 1ſt, heat; 2dly, dilatation in all ſolid bodies, and rarefaction in all fluids; 3dly, motion.

The firſt effect of elementary fire on bodies is heat: heat ariſes wholly from fire, and in ſuch a manner, that the meaſure of heat is always the meaſure of fire; and that of fire, of heat; ſo the heat is inſeparable from the fire.

The ſecond effect of elementary fire is dilatation in all ſolid bodies, and rarefaction in all fluids.

Numerous experiments make it evident, that both theſe are inſeparable from heat. If you heat an iron rod, it will increaſe in all its dimenſions; and the more it is heated, the farther it will be increaſed; and being again expoſed to the cold, it will contract, and ſucceſſively return through all degrees of its dilatation, till it arrive at its firſt bulk, being never two minutes ſucceſſively of the ſame magnitude.

The like may be obſerved in gold, the heavieſt of all bodies, which takes up more ſpace when it is fuſed than it did before; nay, even mercury, the heavieſt of all fluids, has been known to aſcend above thirty times its height, being placed over the fire in a tube.

The laws of this expanſion are;

1ſt, That the ſame degree of fire rarefies fluids ſooner, and in a greater degree than it does ſolids. Without this, the thermometer would be of no uſe; ſince, if it were otherwiſe, the cavity of the tube would be dilated in the ſame proportion as the fluid is rarefied.

2dly, By how much the liquor is lighter, by ſo much the more it is dilated by fire: thus air, which is the lighteſt of all fluids, expands the moſt, and ſpirit of wine the next after air.

The third effect of fire on bodies is motion; for fire, in warming and dilating bodies, muſt neceſſarily move their parts. And in effect, all the motion of nature ariſes from fire alone; and if this were taken away, all things would become immoveable. All oils, fats, waters, wines, ales, ſpirits of wine, vegetables, animals, &c. become hard, rigid, and inert, upon the abſence of only a certain degree of fire; and this induration will be both the ſooner, and the more violent, the leſs the degree of fire is.

Hence, if the fire was abſolutely taken away, and there were the greateſt degree of cold, all nature would grow into one concrete body, ſolid as gold, and hard as a diamond; but, upon the application of fire, it would recover its former mobility.

And, of conſequence, every diminution of fire is attended with a proportionable diminution of motion.

Pure fire is found in two different manners, either as it exiſts every where, and is diffuſed equally in all places; or as it exiſts in certain bodies, in which it makes no great alteration.

That fire ſhould exiſt in the ſame quantity in all places, will ſeem a ſtrange paradox; and yet that it does ſo, is demonſtrable from innumerable experiments.

This elementary fire is preſent every where, in all bodies, all ſpace, and at all times, and that in equal quantities; for let a perſon go where he will, to the top of the higheſt mountains, or deſcend into the loweſt cavern, whether the ſun ſhine or not; either in the moſt ſcorching ſummer, or the ſharpeſt winter; fire may be collected by ſeveral methods, as attrition or otherwiſe. In a word, there is no phyſical point aſſignable without fire, no place in nature where the attrition of two ſticks will not render it ſenſible.

The Carteſians, as Marriotte, Perrault, &c. hold, That there is a large ſtock of fire in a perfect vacuum, i. e. a ſpace out of which all the air has been exhauſted, as ſuppoſing an abſolute vacuum impoſſible: now, the moſt perfect vacuum that we can arrive at, is that of Mr. Hugyens's contrivance, which is as follows: heat a quantity of the pureſt mercury to the heat of boiling water, and pour it into a hot tube of about forty inches long; and when the tube is filled, apply a finger upon the orifice of it, and thus invert it into a baſon full of mercury: the mercury will now be ſuſpended in the tube to the whole height; but then, if you give it but a little ſhake, it will ſink down to the height of about twenty-nine inches, and thus leave a vacuity of eleven inches.

Yet here the philoſophers above-mentioned deny there is any vacuum, and urge, that now ſo much the more fire is entered into the ſpace as there was of other matter; but this is contrary to experience; at leaſt, the fire contained there is no hotter than the mercury itſelf; for if a drop or two of water be in a froſty ſeaſon ſprinkled both upon the upper part of the tube, ſuppoſed to be full of fire, and on the lower that is full of mercury, they will in each place freeze alike; ſo that there is no more pure fire in a perfect vacuum, than in any other place.

But whereas it has been ſaid, that fire is found in all bodies, to prove this, ſet gold againſt the vacuum before-mentioned, and this gold, though the moſt ponderous of all bodies, will not contain more fire than Huygens's vacuum, as appears from the thermometer.

But the fire in gold, when ready to fuſe, is pure fire; for a maſs of this being once heated red hot, will retain this fire perfectly for three days; nay, the prince of Mirandola and others, have kept gold ignited for two months, without any diminution of weight.

Mr. Graveſande, Phyſ. Element, ſays, That bodies of any kind, being violently moved againſt one another, will grow hot by ſuch friction; and this to a conſiderable degree, which ſhews that all bodies have fire in them; for fire may be put in motion, and ſeparated from a body by ſuch rubbing, but can never be generated that way.

Mr. Boyle, Mech. Prod. of Heat, ſays, That although quickſilver is allowed to be the coldeſt of all fluids, inſomuch that many deny, that it will produce any heat by its immediate action on any other body, and particularly on gold; yet ſeveral trials have aſſured him, that a particular mercury may by preparation be enabled ſuddenly to inſinuate itſelf into the body of gold, whether calcined or crude, and become manifeſtly hot with it in leſs than two or three minutes.

Mr. Graveſande ſays, That quickſilver contains fire, is evident hence, that if you ſhake it about in an exhauſted glaſs, it will appear all luminous.

Elementary fire of itſelf always lies concealed; nay, it may be perfectly undiſcoverable, where it is in the greateſt quantity; as is evident in the torrid zone, where the ſnow never melts, notwithſtanding the great abundance of fire.

This fire, in itſelf thus perfectly latent, may diſcover itſelf to be preſent by five effects; 1ſt, by rarefying bodies, and particularly air; 2dly, by light; 3dly, by colour; 4thly, by heat; and 5thly, by burning.

That there is a good quantity of fire even in the coldeſt places, and in the coldeſt bodies, is confirmed by the following experiment: if you take two large iron plates, and rub them briſkly together in Iceland, which is only twelve degrees ſhort of the north pole, in the moſt froſty ſeaſon, and at midnight, they will grow warm, glow, ſhine, and heat to ſuch a pitch as not only to rarefy the ſpirit in the thermometer, but even to ignite, and at laſt to fuſe.

Now the fire here found is either created de novo, or it was there before, but nobody will aſſert its creation; and accordingly, unleſs it be furniſhed with a proper fuel, it will be ſoon diſſipated again, but not annihilated; and of conſequence it pre-exiſted, and it appears to be true fire by its rarefying the ſpirit in the thermometer.

From this, and many other experiments, it is evident, that fire is always found in all parts of ſpace, and in all bodies equally ſpread on the utmoſt top of the higheſt mountain, as in the ſubject valley, or in the deepeſt cavern under ground, and in every climate, and at every ſeaſon.

The equable diſtribution of fire in all places being proved, it ſhould thence follow, that there is the ſame degree thereof every where; which would really be ſo, were it not that fire happens by one means or other to be more collected in one place than another.

But, notwithſtanding the equable difference, &c. of fire through all the mundane ſpace does not hinder, but that, to our ſenſes, it appears very unequal in different places; and hence we have two vulgarly reputed ſources or funds of fire, viz. in the ſun, and the center of the earth.

As for the firſt, we have the concurrent opinions of the philoſophers of all ages, but one excepted, who held the ſun to be cold.

As to the ſecond, the central fire, it is manifeſt that there is an ample proportion of fire under ground; and even, that fire appears much more abundant there than on the ſurface; ſo that at leaſt, a ſubterraneous fire muſt be granted.

Thus they who dig mines, wells, &c. conſtantly obſerve, that while they are but a little below the ſurface, they find it a little cool; and as they proceed lower, it proves much colder, as being beyond the reach of the ſun's heat, inſomuch that water will freeze almoſt inſtantaneouſly, and hence is the uſe of houſes.

But a little lower, about forty or fifty feet deep, it begins to grow warmer, ſo that no ice can bear it; and then the deeper they go, ſtill the greater heat; till at length it endangers the ſtoppage of reſpiration, and puts out their candles. If they venture yet farther with a lighted candle, the place ſhall be immediately found full of flame, as once happened in the coal-pits in Scotland, where a hardy digger, deſcending to an unuſual depth, with a light in his hand, the fumes, which were there found very copious, caught fire thereby, and burnt the whole mountain down.

Therefore it ſeems as if nature had lodged another ſun in the center of the earth, to contribute on its part to the giving motion to bodies, and for the promoting of generation, nutrition, vegetation, germination, &c. of animals, vegetables, and foſſils.

As to the origin of this ſubterraneous ſun, ſome doubt whether it were formed there in the beginning, like the ſun in the firmament, or gradually produced by a ſecondary collection of vague fire into this place.

What makes in favour of the former opinion, are volcanos or burning mountains, which ſeem to have exiſted from the firſt ages; for the flames of mount Ætna are mentioned as of great antiquity, and there are likewiſe ſuch mountains found in the coldeſt regions, viz. Nova Zembla and Iceland, as well as the hotteſt, as Borneo, &c.

It cannot be reaſonably pretended, ſays Mr. Boyle, that the ſubterraneous heat proceeds from the rays of the ſun, ſince they heat not the earth above ſix or ſeven feet deep, even in the ſouthern countries; and if the lower part of the earth were of its own nature cold, and received the heat it affords only from the ſun and ſtars, the deeper men deſcend therein, the leſs degree of heat and ſteams they would meet with.

The ſun contributes much in bringing fire to light, by reaſon of his rapid motion round his axis; whereby the fiery particles, every where diffuſed, are directed and determined in parallel lines toward certain places where its effects become apparent.

And from thence it is, that the fire is perceived by us when the ſun is above; but that when he diſappears, his impulſe or preſſion being then taken away, the fire continues diſperſed at large through the ethereal ſpace.

There is not, in effect, leſs fire in our hemiſphere in the night time, than there is in the day time; only it wants the proper determination to cauſe it to be perceived.

The effects of elemental fire may be increaſed divers ways, viz. firſt, by attrition, or a ſwift rubbing or agitating one body againſt another. This is very manifeſt in ſolids. The attrition of a flint againſt a ſteel produces ſparks of fire; and likewiſe in fluids, the violent agitation of cream, by churning, will produce a ſenſible warmth, and ſeparate it into butter; and this effect is rendered ſtill more diſcernible by a thermometer.

And the heat of animal bodies is owing to the agitation and attrition of the parts of theſe juices againſt each other, and the ſides of the veſſels.

The ſecond manner of increaſing the effect of elementary fire is, by throwing a quantity of moiſt or green vegetables, cut down while full of ſap, into a large heap, and preſſing them cloſe down; by which they grow warm, hot, ſmoke, and break out into flame,

A third way is by mixing certain cold bodies: thus water, and ſpirit of wine, being firſt warmed, grow much hotter by being mixed; alſo oil of cloves, cinnamon, &c. being mixed with ſpirit of wine, become exceeding hot, and burſt forth like volcanos.

The like effects may be had from ſeveral hard and dry bodies, as ſulphur and ſteel filings.

To conclude: on fire and the effects thereof, depend all fluidity of humours, juices, &c. all vegetation, putrefaction, fermentation, animal heat, &c.

As all the four elements, water, air, earth, and fire, are very conducive to the work of vegetation, and no one of them more than this of fire; I conclude, that theſe few hints, which I have collected from the moſt approved authors, concerning the nature and properties of it, as they may be uſeful, would not be unacceptable to the ingenious and ſtudious practiſers of horticulture, which induced me to inſert them here.

FIR-TREE. See Abies.

FISTULAR FLOWERS [Flores Fiſtulares, of Fiſtula, *Lat.* a pipe] ſuch as are compounded of many long, hollow, ſmall flowers, like pipes.

FLAMMULA JOVIS. See Clematis.

FLESH, among botaniſts, is all the ſubſtance of any fruit that is between the outer rind and the ſtone, or that part of any root that is fit to be eaten.

FLORIFEROUS [florifer, *Lat.*] bearing flowers.

FLORIST, one who is converſant with, or ſkilled in flowers.

FLORULENT, FLORULOUS [florentulus, florulus, *Lat.*] Flowery, full of flowers; alſo bloſſoming.

FLOS AFRICANUS. See Tagetes.

FLOS PASSIONIS. See Passiflora.

FLOS SOLIS. See Helianthus.

FLOS TRINITATIS. See Viola.

FLOWER: a flower is a natural production which precedes the fruit, which includes the grain or ſeed. Though a flower is a thing ſo well known, yet the definition of this part of a plant is as various almoſt as the authors who define it. Jungius defines it to be the more tender part of a plant, remarkable for its colour, or form, or both, cohering with the fruit. Yet this author himſelf confeſſes, that this definition is too narrow; for ſome of thoſe bodies which he allows to be flowers are remote from the fruit.

Mr. Ray ſays, it coheres, for the moſt part, with the rudiments of the fruit. Thus the words, for the moſt part are hardly to be admitted into definitions.

Tournefort defines it to be a part of a plant very often remarkable for its peculiar colours, for the moſt part adhering to the young fruit, to which it ſeems to afford the firſt nouriſhment, in order to explicate its moſt tender parts. Which definition is ſtill more deficient than the former, by this uncertain mode of expreſſion.

Pontedera, the profeſſor of botany at Padua, defines it to be a part of a plant unlike the reſt in form and nature; if the flower has a tube, it always adheres to the embryo, or is very near it, for whoſe uſe it is ſubſervient; but if it wants a tube, there is no embryo adhering.

This definition is far from being clear, for it is ſcarce intelligible, and is liable to this objection, that it may include ſome parts of a plant which no perſon ever called by that name; for a root, a ſtalk, or a leaf, are parts of a plant unlike the reſt in form and nature, having no tube, and ſo do not adhere to any embryo, and thus by Pontedera's definition are flowers.

Monſ. Juſſieu, the Paris profeſſor, ſeems not to have ſucceeded much better in this affair: he ſays, That is properly called a flower, which is compoſed of chives, and a piſtillum, and is of uſe in generation. But this is too defective; for there are many plants in which the piſtillium or ſtyle is found a conſiderable diſtance from the chives; there are many flowers that have no piſtillum, whether that word be taken to ſignify the embryo of the fruit, or its appendix, and many which have no chives.

But the late Monſieur Vaillant ſeems to be happier, in forming a clearer idea of this part of a plant. We find in the lecture he read in the Royal Garden at Paris, that the flowers, ſtrictly ſpeaking, ought to be reckoned the organs which conſtitute the different ſexes in plants; ſeeing they are ſometimes found without any covering, and that the coats or petals, which immediately encompaſs them, are deſigned only to cover and defend them: but (ſays he) as theſe coats are the moſt conſpicuous and moſt beautiful part of the compoſition, which is called by the name of flower; to theſe coats therefore I give the name of flower, of whatſoever ſtructure or colour they be; whether they encompaſs the organs of both ſexes together, or contain only one of them, or only ſome parts depending on one of them, provided always that they be not of the ſame figure of the leaves of the plant.

But, in my opinion, Dr. Martyn has been happier, in his definition of a flower, than all thoſe abovementioned: he defines a flower to be the organs of generation of both ſexes adhering to a common placenta, together with their common coverings; or of either ſex ſeparately, with its proper coverings, if it have any.

The parts of a flower are, 1. The germen or ovary; which is the rudiment of the fruit, and ſo is properly the female organ of generation.

2. The ſtyle, which is a body accompanying the ovary, either ariſing from the top of it, or ſtanding as an axis in the middle, with the embryos of the ſeeds round it.

3. The ſummits, or apices, which are thoſe bodies that contain the prolific powder, analogous to the male ſperm in animals; and generally hang upon ſlender threads, which are called the chives or ſtamina.

The petals are thoſe tender fine coloured leaves, which are generally the moſt conſpicuous parts of a flower.

The empalement, or calyx, is thoſe tender leaves which cover the other parts of a flower.

Flowers, according to the number of their petals, are called monopetalous, dipetalous, tripetalous, tetrapetalous, &c.

The ſtructure of flowers is indeed very various; but, according to Dr. Grew, the generality have theſe three parts in common, viz. the empalement, the foliation, and the attire.

Mr. Ray reckons, that every perfect flower has the petals, ſtamina, apices, and ſtylus or piſtil; and ſuch as want any of theſe parts, he accounts imperfect flowers.

In moſt plants there is a perianthum, calyx, or flower-cup; which is of a ſtronger conſiſtence than the flower itſelf, and deſigned to ſtrengthen or preſerve it.

Flowers are diſtinguiſhed into male, female, or hermaphrodite.

The male flowers are thoſe in which are the ſtamina, but have no germen or ſtyle, the ſame which botaniſts call ſtamineous flowers; theſe have no fruit.

The female flowers are ſuch as contain the germen and ſtyle, or piſtil, which is ſucceeded with fruit, and are called fruitful, or knitting flowers.

The hermaphrodite flowers are ſuch in which the two ſexes are contained, i. e. the male and female parts are found in the ſame flower, which are the moſt general kind; ſuch are the Daffodil, Lily, Tulip, Althæa, Geranium, Roſemary, Sage, Thyme.

The ſtructure of parts is much the ſame in thoſe where the ſexes are divided; the difference between them conſiſting in this, that the ſtamina and ſummits or apices, i. e. the male parts in theſe are ſeparate from the ſtyles or piſtils; being ſometimes on the ſame plants, and ſometimes on different ones.

Among the plants which bear both male and female parts, but at a diſtance from each other are reckoned the Cucumber, Melon, Gourd, Turky-Wheat, Walnut, Oak, Beech, &c.

FLUIDITY. [Fluiditas, of fluere, *Lat.* to flow.] Having occaſion to mention fluids and fluidity, in ſpeaking of the properties of the elements air, water, fire, &c. I thought it neceſſary, in this place, to give the following account of that property, which I have extracted from the moſt approved authors.

A fluid, or fluid body, is by ſome defined to be a body, whoſe particles are but weakly connected, their mutual coheſion being, in a great meaſure, prevented from ſome external cauſe: in which ſenſe, a fluid ſtands oppoſed to a ſolid; and is, by the excellent Sir Iſaac Newton, defined to be one whoſe parts eaſily give place, or move out of the way, on any force impelled upon them, and by that means do ſo eaſily move one over another. Which definition is much better than that of Deſcartes, That a fluid is a body whoſe parts are in continual motion, becauſe it is neither apparent that the parts of all fluids are ſo, nor that the parts of ſome ſolid bodies are not ſo.

Fluidity is the ſtate or affection of bodies, which denominates or renders them fluid, and ſtands in direct oppoſition to firmneſs and ſolidity.

It is diſtinguiſhed from liquidity and humidity, in that the idea of fluidity is abſolute, and the property contained within the thing itſelf; whereas that of humidity is relative, and implies wetting, or adhering, i. e. ſomething that gives us the ſenſation of wetneſs or moiſture, and would have no exiſtence, but for our ſenſes.

Thus melted metals, air, æther, and even ſmoke, and flame itſelf, are fluid bodies, and not liquid ones; the parts of them being actually dry, and not leaving any ſenſe of moiſture.

Fluidity ſeems to conſiſt in this, that the parts of any body, being fine and ſmall, are ſo diſpoſed by motion and figure, as that they can eaſily ſlide over one another's ſurfaces all manner of ways. Mr. Boyle alſo obſerves, That it is requiſite they ſhould be variouſly and ſeparately agitated to and fro, and that they ſhould touch one another but in ſome parts only of their ſurfaces. And the ſame gentleman ſays, in his Hiſtory of Fluidity, That the conditions requiſite to conſtitute a fluid body, are chiefly the three following.

1ſt, The minuteneſs or ſmallneſs of its parts: thus we ſee the fire, by dividing metals into parts very fine and ſmall, will melt them, and make them fluid; and after the ſame manner do acid menſtruums diſſolve them, ſuſpend their liquor, and render them fluid; and that fire turns the hard body of common ſalt almoſt wholly into a liquor by diſtillation: though it is not improbable, but that the ſhape and figure of theſe ſmall parts may conduce much towards producing this quality of fluidity; for it is found in the diſtillation of Olive oil (which is a fluid made only by preſſure) that moſt of the oil will, by the action of the parts of the fire (if it be done in a retort) be turned into a kind of conſiſtent ſubſtance like butter.

Likewiſe mercury, whoſe parts are, without doubt, much groſſer than thoſe of oil and water, is yet more fluid than either of them.

2dly, It ſeems requiſite to fluidity, that there be ſtore of vacuities, or vacant ſpaces, interſperſed between the corpuſcles of the fluid body; for elſe there will not be room for each particle to continue its motion and agitation on the ſurfaces of the neighbouring ones. For,

3dly, The chief condition requiſite to conſtitute a fluid body is, that its particles be agitated variouſly and apart, either by their own proper motion, or by ſomething of ſubſtance, that tumbles them up and down by its paſſage through them.

That this qualification is chiefly requiſite to fluidity, you may gather from that common experiment of putting a little dry powder of alabaſter, or plaſter of Paris, finely ſifted, in a flat-bottomed veſſel over the fire; for in a little time it will boil like water, and imitate all the motions of a boiling liquor; it will tumble variouſly over in great waves like that; it will bear ſtirring with a ſtick or ladle without reſiſting, as it will do when cold; nay, if it be ſtirred ſtrongly near the ſide of the veſſel, its waves will apparently daſh up againſt the ſides: yet if any of it be ſpeedily taken out, and laid on a piece of paper, you will ſee nothing but a dry powder.

So that it is evident from hence, that there is a real difference between a fluid body and a wetting liquor; for not only this boiling powder and melted metals, but the air and æther, and even flame itſelf, are properly fluid bodies, though not moiſt liquors.

This ingenious gentleman found alſo, that by blowing the ſmoke of Roſemary into a glaſs pipe, and then holding the pipe (when filled) upright, the ſurface of the ſmoke would accommodate itſelf to a level ſituation; and which way ſoever the tube was inclined, the ſuperficies of the ſmoke would be parallel to the horizon; and when the glaſs was much inclined, would run along it like water.

From whence he infers, that, in order to the rendering a body fluid, there is no need that its parts ſhould be cloſely condenſed, as thoſe of water are.

And Dr. Hook, in his Micrograph. p. 12. preſents us with a very pretty experiment or two, to prove this account of fluidity, viz. That a diſh of ſand being ſet on a drum head, briſkly beaten by the ſticks, or on the upper ſtone of a mill, turning ſwiftly round on the (empty) lower one, it in all reſpects, emulate the properties of a fluid body; for a heavy body will immediately ſink in it to the bottom, and a light one emerge to the top; each grain of ſand hath a conſtant vibrating, dancing motion; and if a hole be made in the ſide of the diſh, the ſand will ſpin out like water.

The corpuſcular philoſophy, before it was wonderfully improved by Sir Iſaac Newton, did not go to the bottom of this matter; for it gave no account of the cauſe of the chief condition requiſite to conſtitute a fluid body, viz. the various motions and agitations of its particles: but this may, in a great meaſure, be accounted for, if it be ſuppoſed to be one of the primary laws of nature, That as all particles of matter attract one another when they come within a certain diſtance, ſo likewiſe they fly away from, and avoid one another, at all greater diſtances from one another.

For then, though their common gravity may keep them together in a maſs (it may ſometimes be) together with the preſſure of other bodies upon them; yet their continual endeavour to avoid one another ſingly, and the adventitious impulſes of light, heat, or other external cauſes, may make the particles of fluids continually move round about one another, and ſo produce this quality.

It is indeed a difficulty not eaſily got over, to account for the particles of fluids always keeping at ſuch a diſtance from one another, as not to come within the ſphere of one another's attraction.

The fabric and conſtitution of that fluid body, water, is amazing; that a body ſo very rare, and which has a vaſt over-proportion of pores, or interſperſed vacuity, to ſolid matter, ſhould yet be perfectly incompreſſible by the greateſt force; and yet this fluid is eaſily reducible into that firm, tranſparent, friable body which we call ice, by being only expoſed to a certain degree of cold.

One would think, that though the particles of water cannot come near enough to attract each other, yet the intervening frigorific matter doth, by being mingled per minima, ſtrongly attract them, and is itſelf likewiſe ſtrongly attracted by them, and wedges or fixes all the maſs into a firm body; which ſolid body loſes its ſolidity again, when by heat the vinculum is ſolved, and theſe frigorific particles are diſjoined from thoſe of the water, and are forced to fly out of it; and, perhaps, juſt thus may the fumes of lead fix quickſilver.

When a firm ſolid body, ſuch as a metal, is by heat reduced into a fluid, doth not the fire disjoin and ſeparate its conſtituent particles, which mutual attraction cauſed to cohere before, and keep them at ſuch a diſtance from each other, as that they are without the ſphere of one anothers attraction as long as that violent motion laſts? And do not they, when that is over, and the heat is flown out, come nearer to, attract one another, and coaleſce again?

As therefore the cauſe of coheſion of the parts of ſolid bodies appears to be their mutual attraction, ſo the chief cauſe of fluidity ſeems to be a contrary motion impreſſed on the particles of fluids, by which they avoid and fly one another, as ſoon as they come at, and as long as they keep at, ſuch a diſtance from each other.

It is obſerved alſo in fluids, that the direction of their preſſure againſt the veſſels which contain them, is in lines perpendicular to the ſides of ſuch veſſels; which property being the neceſſary reſult of the particles of any fluid's being ſpherical, it ſhews that the parts of all fluids are ſo, or of a figure nearly approaching thereto.

Dr. Clarke ſays, That if the parts of a body do not touch each other, or eaſily ſlide over one another, and are of ſuch a magnitude as that they may be eaſily agitated by heat, and the heat be ſufficiently great to agitate them; though perhaps it may be leſs than ſuffices to prevent water from freezing; or even though the parts be not actually moved, yet if they be ſmall, ſmooth, ſlippery, and of ſuch a figure and magnitude as diſpoſes them to move and give way, that body is fluid.

And yet the particles of ſuch fluid bodies do, in ſome meaſure, cohere; as is evident hence, that mercury, when well purged of air, will be ſuſtained in the barometer to the height of ſixty or ſeventy inches; that water will aſcend in capillary tubes, even in vacuo; and that the drops of liquors in vacuo run into a ſpherical form, as adhering by ſome mutual coheſion, like that between poliſhed marble planes.

To this may be added, that theſe ſaid bodies, if they conſiſt of particles which are eaſily entangled with each other, as oil; or if they be capable of being ſtiffened by cold, and joined by the interpoſition of certain cunei or wedges, as water, they are eaſily rendered hard; but if their particles are ſuch as can neither be entangled as air, nor ſtiffened by cold, as quickſilver, then they never grow hard and fixed.

In ſhort, the Carteſians define a fluid to be a body, the parts of which are in continual inteſtine motion; and Dr. Hook, Mr. Boyle, and Dr. Boerhaave, tho' they differ in opinion widely from Carteſianiſm, ſubſcribe to the definition, and alledge arguments to prove, that the parts of fluids are in continual motion, and even that it is this motion which conſtitutes fluidity; and the latter of them aſcribes this, and all motion, to fire. See Fire.

Fluids then are either natural, as water and mercury; or animal, as blood, milk, bile, lympha, urine, &c. or factitious, as wines, ſpirits, oils, &c.

FŒNICULUM. Tourn. Inſt. R. H. 311. tab. 164. Anethum. Lin. Gen. Plant. 326. *Fennel*; in French, *Fenouil.*

The Characters are,

It hath an umbellated flower; the great umbel is compoſed of many ſmaller, which have no involucrum; the umbel is uniform; the flowers have five incurved petals, and five ſtamina, terminated by roundiſh ſummits: the germen is ſituated under the flower, ſupporting two ſmall ſtyles, crowned by roundiſh ſtigmas. The germen afterward turns to an oblong fruit, deeply channelled, dividing into two parts, each containing a ſingle ſeed, flat on one ſide, but convex and channelled on the other.

This genus of plants is ranged in the ſecond ſection of Tournefort's ſeventh claſs, which includes the herbs with umbellated flowers diſpoſed circularly, whoſe empalement turns to two narrow, oblong, thick ſeeds. Dr. Linnæus has joined this genus to Anethum, which is placed in the ſecond ſection of his fifth claſs, with thoſe plants whoſe flowers have five ſtamina and two ſtyles. But as the ſeeds of Fennel are oblong, thick, and channelled, and thoſe of Dill flat and bordered, it is much better to keep them ſeparate, than to join them in the ſame genus.

The Species are,

1. Foeniculum (*Vulgare*) foliis decompoſitis, foliolis brevioribus multifidis, ſemine breviore. *Fennel with decompounded leaves, whoſe ſmall leaves are ſhorter and end in many points, and a ſhorter ſeed.* Fœniculum vulgare Germanicum. C. B. P. 147. *Common Fennel.*
2. Foeniculum (*Dulce*) foliis decompoſitis, foliolis longioribus, ſemine longiori. *Fennel with decompounded leaves, whoſe ſmall leaves are very long, and a longer ſeed.* Fœniculum dulce, majore & albo ſemine. J. B. 3. p. 2, 4. *Sweet Fennel having a larger white ſeed.*
3. Foeniculum (*Azoricum*) humilius, radice cauleſcente carnoſo, ſeminibus recurvis, radice annuâ. *Dwarf Fennel with a fleſhy ſtalk, recurved ſeeds, and an annual root.* Fœniculum dulce Azoricum. Pluk. Alm. *Sweet Azorian Fennel, called Finochio.*

The firſt ſort is the common Fennel, which is cultivated in the gardens, and has ſown itſelf in many places, where it has been introduced in ſuch plenty, as to appear as if it were a native in England; but it is no where found at a great diſtance from gardens, ſo has been undoubtedly brought into England. There are two varieties of this, one with light green leaves, and the other with very dark leaves; but theſe I believe are only varieties which ariſe from the ſame ſeeds; but this is very difficult to aſcertain; for unleſs the ſeeds were ſown ſeparately in ſome place where neither of theſe plants have been growing before, it cannot be done; for the ſeeds of theſe plants which have ſcattered, will remain in the ground ſome years, and when expoſed near the ſurface will grow; ſo that the plants become troubleſome weeds, wherever their ſeeds have been ſuffered to ſcatter; and they frequently come up where other ſeeds are ſown, and thereby the two ſorts may accidentally mix.

The common Fennel is ſo well known, as to need no deſcription. This hath a ſtrong fleſhy root, which penetrates deep into the ground, and will continue ſeveral years. It flowers in July, and the ſeeds ripen in autumn. The beſt time to ſow the ſeeds, is ſoon after they are ripe; the plants will come up in the autumn or the following ſpring, and require no other care but to keep them clean from weeds, and thin the plants where they are too cloſe; it will grow in any ſoil or ſituation. The leaves, ſeeds, and roots of this, are uſed in medicine; the root is one of the five opening roots, and the ſeed one of the greater carminative ſeeds. There is a ſimple water made from the leaves, and a diſtilled oil from the ſeed.

The ſweet Fennel has been by many ſuppoſed only a variety of the common ſort, but I have cultivated it in the ſame ground with that, where it has always retained its differences. The leaves of this are very long and ſlender, growing more ſparſedly, and do not end in ſo many points as thoſe of the common ſort; the ſtalks do not riſe ſo high, and the ſeeds are longer, narrower, and of a lighter colour. Theſe ſeeds are generally imported from Germany or Italy, and are by ſome preferred to thoſe of the common ſort for uſe, being much ſweeter.

This may be propagated in the ſame manner as the former ſort, being very hardy, but the roots are not of ſo long duration.

The third ſort is ſuppoſed to have been originally brought from the Azorian Iſlands; it has been long cultivated in Italy as a ſallad herb, under the title of Finochio; and there are ſome few gardens in England, where it is now cultivated, but in ſmall quantities, for there are not many Engliſh palates which reliſh it, nor is it eaſy to be furniſhed with good ſeeds; thoſe which are annually brought from Italy ſeldom prove good; and it is difficult to ſave it in England, becauſe the winter frequently kills thoſe plants which are left for ſeeds; and when any good plants of the early ſowing are left for ſeeds, they do not ripen, unleſs the winter proves very favourable.

This ſort hath very ſhort ſtalks, which ſwell juſt above the ſurface of the ground, to four or five inches in breadth, and almoſt two thick, being fleſhy and tender: this is the part which is eaten when blanched, with oil, vinegar, and pepper, as a cold ſallad. When theſe plants are permitted to run for ſeeds, the ſtalks do not riſe more than a foot and a half high, having a large ſpreading umbel ſtanding on the top. The ſeeds of this ſort are narrow, crooked, and of a bright yellow colour; they have a very ſtrong ſmell like Aniſeed, and are very ſweet to the taſte.

The manner of cultivating this plant is as follows: Your firſt care muſt be to procure good ſeeds from ſome perſon who has been careful in the choice of the plants, otherwiſe there will be little hope of having it good; for the plants will run up to ſeeds before they ſwell to any ſize, ſo will not be fit for uſe: then make choice of a good ſpot of light rich earth, not dry nor very wet, for in either extreme this plant will not thrive. The firſt crop may be ſown about a fortnight in March, which, if it ſucceeds, will be fit for uſe in July; and by ſowing at ſeveral times, there may be a ſupply for the table till the froſt puts a ſtop to it. After having well dug and levelled the ground ſmooth, you muſt make a ſhallow drill by a line, into which you muſt ſcatter your ſeeds pretty thin; for if your plants are ſix inches aſunder in the rows, it will be full near enough; but however, you muſt expect ſome of your ſeeds to fail, and therefore you ſhould ſcatter them about two inches diſtance; then cover the ſeeds about half an inch thick with earth, laying it ſmooth: theſe drills ſhould be made eighteen inches aſunder, or more, that there may be room to clean the ground, as alſo to earth up the plants when they are full grown. When the plants come up, which will be in about three weeks or a month after ſowing, you muſt with a ſmall hoe cut up all the weeds between them, and where the plants are too cloſe, they ſhould be thinned to about three inches diſtance; and as they advance, and the weeds ſpring again, they ſhould, from time to time, be hoed; and at the laſt time of thinning them, they ſhould be left ſeven or eight inches aſunder at leaſt. If your kind be good, the ſtems of the plants will increaſe to a conſiderable bulk juſt above the ſurface of the ground; which part ſhould be earthed up in the manner of Celery, to blanch, about a fortnight or three weeks before it is uſed, and this will cauſe it to be very tender and criſp.

Your ſecond crop ſhould be ſown about three weeks after the firſt, and ſo continue ſowing every three weeks or a month till the end of July, after which time it will be too late for the plants to come to any perfection. But you ſhould obſerve to ſow in April, May, and June, on a moiſter ſoil than that which you ſowed the firſt on; as alſo what you ſow in the latter part of July, ſhould be ſown on a drier ſoil, and in a warmer ſituation; becauſe this crop will not be fit for uſe till late in autumn, and therefore will be ſubject to injuries from too much wet or cold weather, if on a moiſt ſoil. But as the ground is often extreme dry in June and July, and the ſeeds more apt to miſcarry and not come up, you ſhould therefore obſerve to water and ſhade the beds where this ſeed is ſown at that ſeaſon, until the plants come up. And if the ſeaſon ſhould prove dry, the plants muſt be duly watered, otherwiſe they will run up to ſeed before they are of any ſize; therefore there ſhould be a channel made where every row of plants grow, to detain the water which is poured on them, to prevent its running off. In the autumn, if there ſhould happen ſharp froſts, it will be very proper to cover the plants with ſome Peas-haulm, or other light covering, to prevent their being pinched; by which method they may be continued for uſe till the middle of winter.

A ſmall bed of this plant will be ſufficient at each ſowing for a middling family; and for a large family, a bed of about twenty feet long, and four feet broad, will be full enough at a time.

FŒNUM BURGUNDIACUM. See Medica Sativa.

FŒNUM GRÆCUM. See Trigonella.

FOOT-STALKS, are thoſe ſmall ſtalks which immediately ſuſtain the leaves, flowers, or fruit.

FOUNTAINS are ſources or ſprings of living water, ariſing out of the ground. As to the original of them, ſee under the article Springs.

Of artificial fountains there are great variety, the mechaniſm of which not being to my purpoſe, I will not dwell upon it; though I may aſſert, that they are not only great ornaments to a fine garden, but alſo of great uſe. But they ought not to be placed too near the houſe by reaſon of the vapours that ariſe from the water, which may be apt to ſtrike a damp to the wall, and ſpoil the paintings, &c. and the ſummer vapours may cauſe a malignity in the air, and ſo be prejudicial to the health of the family; and likewiſe the noiſe may be incommodious in the night.

Fountains in a garden ſhould be ſo diſtributed, that they may be ſeen almoſt all at one time, and that the water-ſpouts may range all in a line one with another, which is the beauty of them; for this occaſions an agreeable confuſion to the eye, making them appear to be more in number than they really are. See Jet d'Eau, Springs, Vapours, Water, &c.

FRAGARIA. Lin. Gen. Plant. 558. Tourn. Inſt. R. H. 295. tab. 152. [is ſo called for its fragrant aromatic ſcent.] Strawberries; in French, *Fraſier*.

The Characters are,

The empalement of the flower is of one leaf, which is cut into ten parts at the top. The flower hath five roundiſh petals, which are inſerted in the empalement, and ſpread open. It hath twenty ſtamina, which are inſerted in the empalement, terminated by moon-ſhaped ſummits. It hath a great number of germem collected into a head, each having a ſingle ſtyle, inſerted in the ſide of the germen, crowned by ſingle ſtigmas; this head afterward becomes a large, ſoft, pulpy fruit, which, if left, falls away, leaving many ſmall angular ſeeds in the empalement.

This genus of plants is ranged in the fifth ſection of Linnæus's twelfth claſs, which includes thoſe plants whoſe flowers have at leaſt twenty ſtamina and many ſtyles, which are inſerted to the empalement.

The Species are,

1. Fragaria (*Veſca*) foliis ovatis ſerratis, calycibus brevibus, fructu parvo. *Strawberry with oval ſawed leaves, ſhort empalements, and a ſmall fruit.* Fragaria vulgaris. C. B. P. 226. *The common or Wood Strawberry.*
2. Fragaria (*Virginiana*) foliis oblongo-ovatis ſerratis, infernè incanis, calycibus longioribus, fructu ſubrotundo. *Strawberry with oblong, oval, ſawed leaves, hoary on their under ſide, longer empalements, and a roundiſh fruit.* Fragaria Virginiana fructu Coccineo. Hiſt. Ox. 2. 186. *Virginia Strawberry with a ſcarlet fruit, commonly called the Scarlet Strawberry.*
3. Fragaria (*Muricata*) foliis ovato-lanceolatis rugoſis, fructu ovato. *Strawberry with oval, ſpear-ſhaped, rough leaves, and an oval fruit.* Fragaria fructu parvi pruni magnitudine. C. B. P. 327. *Strawberry with fruit as large as a ſmall Plumb, commonly called Hautboy Strawberry.*
4. Fragaria (*Chiloenſis*) foliis ovatis carnoſis hirſutis fructu maximo. *Strawberry with oval, fleſhy, hairy leaves, and a large fruit.* Fragaria Chiloenſis, fructu maximo foliis carnoſis hirſutis. Hort. Elth. 145. tab. 120. *Strawberry of Chili with a large fruit, and hairy fleſhy leaves, called Frutilla, in America.*

There are ſome other varieties of this fruit, which are now cultivated in England; but I have not ſeen any other which can be called a diſtinct ſpecies, than are here enumerated, and theſe, I think, may be allowed to be ſo, for they never alter from one to the other, by any cultivation, though the fruit is frequently improved, ſo as to be of a larger ſize thereby; therefore thoſe who have ſuppoſed them but one ſpecies, have greatly erred in ſo doing; I ſhall therefore mention the ſeveral varieties of Strawberry, which are at preſent to be found in the gardens under the ſpecies to which they naturally belong.

The firſt ſort is the common Wood Strawberry, which grows naturally in the woods in many parts of England, and is ſo well known as to need no deſcription; of this there are three varieties, 1. The common ſort with red fruit. 2. The white Wood Strawberry, which ripens a little later in the ſeaſon, and is by many perſons preferred to it for its quick flavour, but as it ſeldom produces ſo large crops of fruit as the red ſort, it is not very generally cultivated. 3. The green Strawberry, by ſome called the Pine Apple Strawberry, from its rich flavour. The fruit of this is greeniſh when ripe; it is very firm, and hath a very high flavour; this is a late ripe fruit, but unleſs it is planted in a moiſt loamy ſoil, it is a very bad bearer; but in ſuch land where it does ſucceed, it merits cultivation as much as any of the ſorts.

The Scarlet Strawberry is the ſort which is firſt ripe, for which reaſon it merits eſteem, had it nothing elſe to recommend it; but the fruit is ſo good, as by many perſons of good taſte to be preferred to moſt other ſorts. This was brought from Virginia, where it grows naturally in the woods, and is ſo different from the Wood Strawberry in leaf, flower, and fruit, that there need be no doubt of their being diſtinct ſpecies.

There is a variety of this which hath been of late years introduced from the northern parts of America, which has the appearance of a diſtinct ſpecies. The leaves of this are rounder, and not ſo deeply veined; the crenatures on their edges are broader and more obtuſe. The leaves which compoſe the empalement are much longer, and are hairy, and the fruit is larger; but as in other reſpects it approaches near to the Scarlet Strawberry, I have choſen to join it to that, rather than make a diſtinct ſpecies of it; this I have been informed grows naturally in Louiſiana.

There has alſo been another variety of this (if not a diſtinct ſpecies) lately introduced to our gardens, which is commonly known by the title of Alpine Strawberry; the plants of this greatly reſemble thoſe of the Scarlet Strawberry, but the fruit is more pointed; it is a well flavoured fruit, and continues bearing from the common ſeaſon of Strawberries, until the froſt in autumn puts a ſtop to it, which renders the ſort very valuable: I have frequently gathered the fruit in the beginning of November; this has occaſioned the Dutch gardeners titling it Everlaſting Strawberry.

The Hautboy Strawberry, which the French call Capitons, came originally from America, but it has been long cultivated in the Engliſh gardens, and is very different from the other ſorts in leaf, flower, and fruit, as that no one can doubt of their being different ſpecies; there is an improvement of this ſort, which is commonly called the Globe Hautboy. The fruit of this is larger, and of a globular form, but this difference has certainly ariſen from culture; for where theſe have been neglected a year or two, they have degenerated to the common Hautboy again; where the ground is proper for this plant, and their culture is well managed, the plants will produce great plenty of fruit, which will be large, and well flavoured, and by ſome perſons are preferred to all the other ſorts.

The Chili Strawberry was brought to Europe by Monſ. Frazier, an engineer, who was ſent to America by the late king of France, and was firſt planted in the Royal Garden at Paris, from whence it was communicated to ſeveral curious perſons in Holland, and in the year 1727, I brought a parcel of the plants to England, which were communicated to me by Mr. George Clifford, of Amſterdam, who had large beds of this ſort growing in his curious gardens at Hartecamp. The leaves of this ſort are hairy, oval, and of a much thicker ſubſtance than any ſort yet known, and ſtand upon very ſtrong hairy foot-ſtalks; the runners from the plants are very large, hairy, and extend to a great length, putting out plants at ſeveral diſtances. The foot-ſtalks which ſuſtain the flowers are very ſtrong; the leaves of the empalement are long and hairy. The flowers are large, and are often deformed; and ſo is the fruit, which is very large, and when cultivated in very ſtrong land, the plants produce plenty of fruit, which is firm, and very well flavoured; but as it is a bad bearer in moſt places where it has been cultivated, it has generally been neglected.

The Strawberries in general love a gentle hazelly loam, in which they will thrive and bear greater plenty of fruit than in a light rich ſoil. The ground ſhould alſo be moiſt, for if it is very dry, all the watering which is given to the plants in warm dry ſeaſons, will not be ſufficient to procure plenty of fruit; nor ſhould the ground be much dunged, for that will cauſe the plants to run into ſuckers, and grow luxuriant, and render them leſs fruitful.

The beſt time to remove theſe plants is in October, that they may get new roots before the hard froſt ſets in, which looſens the ground; ſo that if the roots of the plants are not pretty well eſtabliſhed in the ground, the plants are frequently turned out of the ground by the firſt thaw; therefore the ſooner they are planted when the autumnal rains begin, the better will their roots be eſtabliſhed, ſo there will be leſs danger of their miſcarrying, and ſometimes thoſe which are well rooted, will produce a few fruit the firſt year; there are ſome who tranſplant their plants in the ſpring; but where that is done, they muſt be duly ſupplied with water in the dry weather, otherwiſe they will not ſucceed.

The ground in which theſe are planted ſhould be thoroughly cleaned from the roots of Couch, and all other bad weeds; for as the Strawberry plants are to remain three years before they are taken up, ſo if any of the roots of thoſe bad weeds are left in the ground, they will have time to multiply ſo greatly as to fill the ground, and overbear the Strawberry plants. The ground ſhould alſo be well trenched and made level; then the uſual method is to lay it out into beds of four feet broad, with paths two feet or two feet and a half broad between each; theſe paths are neceſſary for the convenience of gathering the fruit, and for weeding and dreſſing of the beds, and alſo for watering the plants; after the beds are marked out, there ſhould be four lines drawn in each, at a foot diſtance, which will leave ſix inches ſpace on each ſide, between the outſide rows and the paths; then the plants ſhould be planted at about a foot diſtance from each other in the rows, in a quincunx order, being careful to cloſe the ground to the roots of the plants when they are planted; and if there ſhould not happen rain ſoon after, the plants ſhould be well watered to ſettle the earth to their roots.

The diſtance here mentioned for the plants to be placed muſt be underſtood for the Wood Strawberries only, for as the other ſorts grow much larger, their diſtances muſt be proportioned to their ſeveral growths; therefore the Scarlets and Hautboys ſhould have but three rows of plants in each bed, which ſhould be at fifteen inches diſtance, and the plants in the rows ſhould be allowed the ſame ſpace from each other, and the Chili Strawberry muſt have but two rows of plants in each bed, which ſhould alſo be two feet apart in the rows; for as theſe grow very ſtrong, if they have not room to ſpread, they will not be very fruitful.

In chuſing proper plants of any of the ſorts, depends the whole ſucceſs; for if they are promiſcuouſly taken from beds without care, great part of the plants will become barren; theſe are generally called blind, which is when there are plenty of flowers, but no fruit produced; if theſe flowers are well examined, they will be found to want the female organs of generation, moſt of them abounding with ſtamina, but there are few, if any ſtyles; ſo that it frequently happens among theſe barren plants, that ſome of them will have a part of an imperfect fruit formed, which will ſometimes ripen; this barrenneſs is not peculiar to Strawberries, but is general to all thoſe plants which have creeping roots, or ſtalks; and the more they increaſe from either, the ſooner they become barren, and this in ſome degree runs through the vegetable kingdom; for trees and ſhrubs which are propagated by cuttings, are generally barren of ſeeds in two generations, that is, when they are propagated by cuttings, which were taken from plants raiſed by cuttings; this I have conſtantly found to hold in great numbers of plants, and in fruit-trees it often happens, that thoſe ſorts which have been long propagated by grafts and buds, have no kernels. But to return to the choice of the Strawberry plants; theſe ſhould never be taken from old neglected beds, where the plants have been ſuffered to ſpread or run into a multitude of ſuckers, nor from any plants which are not very fruitful; and thoſe offſets which ſtand neareſt to the old plants, ſhould always be preferred to thoſe which are produced from the trailing ſtalks at a farther diſtance; and the Wood Strawberry is beſt when the plants are taken freſh from the woods, provided they are taken from fruitful plants, becauſe they are not ſo liable to ramble and ſpread, as thoſe which are taken from plants, which have been long cultivated in gardens; therefore thoſe who are curious in cultivating this fruit, ſhould be very careful in the choice of their plants.

When the plants have taken new root, the next care is if the winter prove ſevere, to lay ſome old tanners bark over the ſurface of the bed between the plants, to keep out the froſt: this care is abſolutely neceſſary to the Chili Strawberry, which is frequently killed in hard winters, where they are expoſed without any covering; therefore where tanners bark cannot eaſily be procured, ſaw-duſt, or ſea-coal aſhes may be uſed; or in want of theſe, if decayed leaves of trees, or the branches of Evergreen-trees with their leaves upon them, are laid over the beds, to prevent the froſt from penetrating deep into the ground, it will ſecure the plants from injury.

The following ſummer the plants ſhould be conſtantly kept clean from weeds, and all the runners ſhould be pulled off as faſt as they are produced; if this is conſtantly practiſed, the plants will become very ſtrong by the following autumn; whereas when this is neglected (as is too frequently ſeen) and all the runners permitted to ſtand during the ſummer ſeaſon, and then pulled off in the autumn, the plants will not be half ſo ſtrong as thoſe where that care has been taken; therefore there will not be near the ſame quantity of fruit upon them the following ſpring, nor will the fruit be near ſo large and fair; and where proper care is taken of the plants the firſt ſummer, there is generally a plentiful crop of fruit the ſecond ſpring; whereas when this is neglected, the crop will be thin and the fruit ſmall.

As this fruit is very common, there are but few perſons who cultivate it with proper care; therefore I ſhall give ſome directions for the doing of it, which, if carefully practiſed, will be attended with ſucceſs.

The old plants of Strawberries are thoſe which produce the fruit, for the ſuckers ſeldom produce any till they have grown a full year; therefore it appears how neceſſary it is to diveſt the old plants of them; for wherever they are ſuffered to remain, they rob the fruitful plants of their nouriſhment in proportion to their number; for each of theſe ſuckers ſend out a quantity of roots, which interfere, and are ſo cloſely matted together, as to draw away the greateſt part of the nouriſhment from the old roots, whereby they are greatly weakened; and theſe ſuckers alſo render each other very weak, ſo that from hence the cauſe of barrenneſs ariſes; for I have known where the old plants have been conſtantly kept clear from ſuckers, they have continued very fruitful four or five years without being tranſplanted; however, it is the beſt way to have a ſucceſſion of beds, that after three years ſtanding they may be taken up; becauſe by that time they will have exhauſted the ground of thoſe vegetable ſalts, neceſſary for the nouriſhment of that ſpecies of plants; for it is always obſerved, that Strawberries planted on freſh land are the moſt fruitful.

The next thing to be obſerved, is in autumn to diveſt the plants of any ſtrings, or runners, which may have been produced, and alſo of all the decayed leaves, and the beds cleared from weeds; then the paths ſhould be dug up, and the weeds buried which were taken from the beds, and ſome earth laid over the ſurface of the beds between the plants; this will ſtrengthen the plants, and prepare them for the following ſpring; and if after this, there is ſome old tanners bark laid over the ſurface of the ground between the plants, it will be of great ſervice to them. In the ſpring, after the danger of hard froſt is over, the ground between the plants in the beds ſhould be forked with a narrow three-pronged fork, to looſen it, and break the clods; and in this operation, the tan which was laid over the ſurface of the ground in autumn will be buried, which will be a good dreſſing to the Strawberries, eſpecially in ſtrong land; then about the end of March, or the beginning of April, if the ſurface of the beds is covered with moſs, it will keep the ground moiſt, and prevent the drying winds from penetrating the ground, and thereby ſecure a good crop of fruit; and the moſs will preſerve the fruit clean, that when heavy rains may fall after the fruit is full grown, there will be no dirt waſhed over them, which frequently happens, ſo that the fruit muſt be waſhed before it is fit for the table, which greatly diminiſhes its flavour; therefore where this method is practiſed, the fruit may be had in perfection.

The ſoil in which the Chili Strawberry is found to ſucceed beſt, is a very ſtrong brick earth, approaching near to clay; in this ſoil I have ſeen them produce a tolerable good crop, and the fruit has been extremely well flavoured; and if ſome care be taken to pull off the runners as they are produced, ſo as to leave only the old plants, I make no doubt but theſe plants may be as fruitful as the common Hautboy: this I mention from one or two experiments, which have been made by my direction, and not from theory.

There are ſome perſons who are ſo fond of Strawberries, as to be at any expence to obtain them early in the year, and to continue them as late in the ſeaſon as poſſible; and ſhould I omit to give ſome directions for both theſe managements, they would ſuppoſe the book very defective; therefore I ſhall mention the practice of ſome few, who have ſucceeded beſt in the management of theſe fruits; I ſhall begin with directions for obtaining theſe fruits early in the ſpring.

Where there are any hot walls erected in gardens for the producing early fruit, it is very common to ſee Strawberries planted in the borders, that the fire which is applied for ripening the fruit againſt the walls, may alſo ſerve the purpoſe of bringing forward the Strawberries; but where this is practiſed, the Strawberry plants ſhould be annually renewed, taking up the plants as ſoon as their fruit is over, and all the earth of the borders ſhould be taken out, at leaſt two feet deep, and freſh earth brought in, which will be equally good for the wall trees; but, as was before obſerved, that the old plants of Strawberries only are thoſe which produce the fruit, there ſhould be a ſufficient number of plants brought up in pots, to ſupply the border annually; and the ſame muſt be done if they are to be raiſed in a common hot-bed, or in ſtoves; therefore I ſhall begin with giving directions for raiſing and preparing plants for thoſe purpoſes.

The ſorts which are the moſt proper for forcing early, are the Scarlet, the Alpine, and the Wood Strawberries, for the Hautboy grows too large for this purpoſe. In the choice of the plants, there ſhould be an eſpecial care taken to have them from the moſt fruitful plants, and thoſe which grow immediately to the old plants; they ſhould be taken off in autumn, and each planted in a ſeparate ſmall pot filled with loamy ſoil, and placed in a ſhady ſituation till they have taken root; after which they may be removed to an open ſituation, where they may remain till the middle or end of November, when the pots ſhould be plunged into the ground up to their rims, to prevent the froſt from penetrating through the ſide of the pots; if theſe are placed near a wall, pale, or hedge, expoſed to an eaſt aſpect, or north-eaſt, they will ſucceed better than in a warm ſituation, becauſe they will not be forced too forward; the only care they require, is to ſecure them from being turned out of the pots after froſt. The ſpring following the plants will be ſo far advanced as to have filled the pots with their roots by the end of April, when they ſhould be turned out of the pots, and their roots pared; then planted into penny pots filled with the like loamy ſoil, and plunged into the ground in a ſhady ſituation, where they ſhould remain the following ſummer; during which time they muſt be duly kept clean from weeds, and all the runners muſt be taken off as faſt as they are produced; likewiſe if there ſhould be any flowers come out, they ſhould alſo be pinched off, and not ſuffered to bear fruit, which would weaken the plants, for there cannot be too much care taken to have the plants as ſtrong as poſſible, that they may produce plenty of fruit, without which they are not worth the trouble of forcing.

About the middle of October, or earlier, if the autumn proves cold, the pots ſhould be removed into a warmer ſituation, to prepare them for forcing; for they ſhould not be ſuddenly removed from a very cold ſituation immediately into the ſtove or hot-bed, but be gradually prepared for it; but where they are deſigned for the borders near a hot wall, they may then be turned out of the pots, and planted into the borders, that they may have time to get freſh rooting, before the fires are made to heat the walls; when theſe are planted, they may be placed very cloſe to each other; for as they are deſigned to remain there no longer than till they have ripened their fruit, they will not require much room, as their roots will find ſufficient nouriſhment below, and alſo from the earth which is filled into the ſpaces between the balls of earth, about their roots; and it is of conſequence to get as much fruit as poſſible in a ſmall ſpace, where there is an expence to force them early. If the fires are lighted about Chriſtmas, the Strawberries in theſe borders will be ripe the end of March; or if the ſeaſon ſhould prove very cold, it may be the middle of April before they will be fit for the table.

In the management of the plants there muſt be care taken to ſupply them with water when they begin to ſhew their flowers, otherwiſe they will fall off without producing any fruit; and, in mild weather, there ſhould be freſh air admitted to them every day; but as fruit-trees againſt the wall muſt be ſo treated, the ſame management will agree with the Strawberries.

If the Strawberries are intended to be forced in a ſtove, where there are Pine-apples, and no room to plunge them in the tan-bed, then the plants ſhould be tranſplanted into larger pots in September, that they may be well rooted before they are removed into the ſtove, which ſhould not be till December; but if they are placed under a frame the beginning of November, where they may be ſcreened from the froſt, it will prepare the plants better for forcing; and thoſe who are deſirous to have them very early, make a hot-bed under frames, upon which they place their plants the latter end of October, which will bring them forward to flower, and then they remove the plants into the ſtove; when theſe plants are removed into the ſtove, they ſhould be placed as near to the glaſſes as poſſible, that they may enjoy the full ſun and air; for when they are placed backward, the plants will draw up weak, and the flowers will drop without producing fruit. As the earth in the pots will dry pretty faſt when they ſtand dry upon the pavement of the hot-houſe, or on ſhelves, ſo the plants muſt be duly watered; but it muſt be done with diſcretion, and not too much given to them, which will be equally hurtful to them; if theſe plants are properly managed, they will produce ripe fruit in February, which is as early as moſt people will chuſe to eat them. When the fruit is all gathered from the plants, they ſhould be turned out of the ſtove; for as they will be of no farther ſervice, they ſhould not remain to take up the room; nor ſhould thoſe plants which are planted in the borders near the hot walls be left there after their fruit is gathered, but immediately taken up, that they may rob the fruit-trees of their nouriſhment as little as poſſible.

Where there is no conveniency of ſtoves, or hot-walls for this purpoſe, the fruit may be ripened upon common hot-beds; and though they may not be quite ſo early as with the other advantages, yet I have ſeen great crops of the fruit ripe in April, which were upon common hot-beds under frames, and executed at a ſmall expence in the following manner.

The plants were prepared in pots after the manner before directed, which were placed in a warm ſituation in the beginning of October, and about Chriſtmas the hot-bed was made in the ſame manner as for Cucumbers, but not ſo ſtrong; and as ſoon as the firſt violent ſteam of the dung was over, ſome old rotten dung laid over the hot-bed to keep down the heat, or where it can be eaſily procured, neats dung is preferable for this purpoſe; then the plants ſhould be turned out of the pots, and placed upon the bed as cloſe together as poſſible, filling up the interſtices between the plants with earth; afterward the plants muſt have air admitted to them every day; and if the heat of the bed is too great, the plants ſhould be raiſed up, to prevent their roots being ſcorched; and if the bed is too cold, the ſides of it ſhould be lined with ſome hot dung: this firſt bed will bring the plants to flower by the latter end of February, or the beginning of March, by which time the heat of the bed will be ſpent, therefore another hot-bed ſhould be prepared to receive the plants, which need not be ſo ſtrong as the firſt; but upon the hot dung ſhould be laid ſome neats dung about two inches thick, which ſhould be equally ſpread and ſmoothed; this will prevent the heat of the bed from injuring the roots of the plants, upon this ſhould be laid two inches of a loamy ſoil; when this has laid two days to warm, the plants ſhould be taken out of the firſt hot-bed, and turned carefully out of the pots, preſerving all the earth to their roots, and placed cloſe together upon this new hot-bed, filling up the vacuities between the balls with loamy earth: the roots of the plants will ſoon ſtrike out into this freſh earth, which will ſtrengthen their flowers, and cauſe their fruit to ſet in plenty; and if proper care is taken to admit freſh air to the plants, and ſupply them properly with water, they will have plenty of ripe fruit in April, which will be full two months before their natural ſeaſon.

The methods practiſed to retard this fruit, is firſt by planting them in the coldeſt part of the garden, where they may be as much in ſhade as poſſible, and the ſoil ſhould be ſtrong and cold; when there are ſuch places in a garden, the fruit will be near a month later than in a warm ſituation; the next is to cut off all the flowers when they firſt appear, and if the ſeaſon proves dry, to water them plentifully, which will cauſe them to put out a freſh crop of flowers; and if they are ſupplied with water, there will be a late crop of fruit, but theſe are not ſo well flavoured as thoſe which ripen in their natural ſeaſon.

But ſince the Alpine Strawberry has been introduced in the Engliſh gardens, there is little occaſion for practiſing this method of retarding the fruit; becauſe this ſort will ſupply the table the whole ſummer, eſpecially if care is taken to pull off the runners; and in dry ſeaſons to water the plants, without which the bloſſoms will fall off, without producing fruit.

There are ſome perſons ſo curious as to raiſe the plants from ſeeds, by which they have greatly improved ſome of the ſorts; and if this was more practiſed, I am certain it would be found of ſingular ſervice, where the faireſt of the fruit of each kind are choſen. The ſeeds ſhould be immediately ſown when the fruit is eaten; the beſt way is to ſow the ſeeds in pots, placing them in the ſhade.

In the ſpring of the year 1724, there was ſcarce any rain from February till about the middle of July, ſo that moſt of the Strawberries and Raſpberries in the gardens near London, were burnt up, and came to no perfection; but upon plenty of rain falling in July, they recovered and put out plenty of flowers, which were ſucceeded by fruit, which ripened in September, when the markets of London were ſupplied with a great plenty of both thoſe fruits at that ſeaſon of the year.

FRANGULA. Tourn. Inſt. R. H. 612. tab. 383. Rhamnus. Lin. Gen. Plant. 235. [is ſo called of frangendo, breaking, becauſe of the brittleneſs of its wood.] Berry-bearing Alder.

The Characters are,

The empalement of the flower is of one leaf, cut at the top into five ſegments, which are erect. The flower hath one petal, which is cut into five acute ſegments; theſe are placed between the ſegments of the empalement, into which they are inſerted, but are ſhorter, and ſtand erect. It hath five ſtamina, which are the length of the petal, terminated by obtuſe ſummits; in the center is ſituated a globular germen, ſupporting a ſlender ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a round berry, incloſing two plain roundiſh ſeeds.

This genus of plants is ranged in the ſecond ſection of Tournefort's twenty-firſt claſs, which includes the trees and ſhrubs with a Roſe flower, whoſe pointal turns to a berry. Dr. Linnæus has joined this genus with the Paliurus, Alaternus, and Ziziphus, to the Rhamnus, making them only ſpecies of one genus; but according to his own ſyſtem, they ſhould be ſeparated to a great diſtance from Rhamnus, and be placed in his twenty-ſecond claſs, becauſe it hath male and female flowers on different plants; whereas it is placed in the firſt ſection of his fifth claſs, from the flower having five ſtamina and but one ſtyle.

The Species are,

1. Frangula (*Alnus*) foliis ovato-lanceolatis glabris. *Frangula with oval, ſpear-ſhaped, ſmooth leaves.* Frangula, ſive alnus, nigra baccifera. Park. Theat. Black Berry-bearing Alder.
2. Frangula (*Latifolia*) foliis lanceolatis rugoſis. *Frangula with rough ſpear-ſhaped leaves.* Frangula rugoſiore & ampliore folio. Tourn. Berry-bearing Alder with a larger and rougher leaf.
3. Frangula (*Rotundifolia*) foliis ovatis nervoſis. *Frangula with oval veined leaves.* Frangula montana pumila ſaxatilis, folio ſubrotundo. Tourn. Low mountain, rocky, berry-bearing Alder, with a round leaf.
4. Frangula (*Americana*) foliis oblongo-ovatis nervoſis, glabris. *Frangula with oblong, oval, ſmooth veined leaves.* Frangula Americana foliis glabris. Dale. *American Berry-bearing Alder with ſmooth leaves.*

The firſt ſort grows naturally in the woods in many parts of England, ſo is ſeldom planted in gardens; this riſes with a woody ſtem to the height of ten or twelve feet, ſending out many irregular branches, which are covered with a dark bark, and garniſhed with oval ſpear-ſhaped leaves, about two inches long, and one inch broad, having ſeveral tranſverſe veins from the midrib to the ſides, and ſtand upon ſhort foot-ſtalks. The flowers are produced in cluſters at the end of the former year's ſhoots, and alſo upon the firſt and ſecond joints of the ſame year's ſhoot, each ſtanding upon a ſhort ſeparate foot-ſtalk, on every ſide the branches; theſe are very ſmall, of an herbaceous colour, and do not expand; they are ſucceeded by ſmall round berries, which turn firſt red, but afterward black when ripe. The flowers appear in June, and the berries ripen in September; this ſtands in the Diſpenſary as a medicinal plant, but is ſeldom uſed.

The ſecond ſort hath larger rough leaves than the firſt. It grows naturally on the Alps and other mountainous parts of Europe, and is preſerved in ſome gardens for the ſake of variety.

The third ſort is of humble growth, ſeldom riſing above two feet high; this grows on the Pyrenean Mountains, and is ſeldom preſerved unleſs in botanic gardens for variety; it may be increaſed by laying down the branches, but muſt have a ſtrong ſoil.

The fourth ſort grows naturally in North America, from whence I received the ſeeds; this is pretty like the firſt ſort, but the leaves are longer and broader; they are ſmooth, of a lucid green, and have many veins. The flowers are very like thoſe of the firſt ſort.

Theſe ſhrubs are eaſily propagated by ſeeds, which ſhould be ſown as ſoon as they are ripe, and then the plants will come up the ſpring following; but if they are kept out of the ground till ſpring, the plants will not come up till the year after. When the plants come up, they muſt be kept clean from weeds till autumn, then they may be taken up and planted in a nurſery in rows, two feet aſunder, and at one foot diſtance in the rows; in this nurſery they may remain two years, and may then be planted where they are to remain; they may alſo be propapated by layers and cuttings, but the ſeedling plants are beſt.

The fruit of the firſt ſort is often brought into the markets of London, and ſold for Buckthorn berries; of which cheat, all ſuch as make ſyrup of Buckthorn ſhould be particularly careful; they may be eaſily diſtinguiſhed by breaking the berries, and obſerving how many ſeeds are contained in each, the berries of this tree having but two, and thoſe of Buckthorn generally four ſeeds in each berry, and the juice of the latter dies paper of a green colour.

FRAXINELLA. See Dictamnus.

FRAXINUS. Lin. Gen. Plant. 1026. Tourn. Inſt. R. H. 577. tab. 343. The Aſh-tree; in French, *Frêne*.

The Characters are,

It hath hermaphrodite and female flowers on the ſame tree, and ſometimes on different trees. The hermaphrodite flowers have no petals, but a ſmall four-pointed empalement, including two erect ſtamina, which are terminated by oblong ſummits, having four furrows. In the center is ſituated an oval compreſſed germen, ſupporting a cylindrical ſtyle, crowned by a bifid ſtigma. The germen afterward becomes a compreſſed bordered fruit, ſhaped like a bird's tongue, having one cell, incloſing a ſeed of the ſame form. The female flowers are the ſame, but have no ſtamina.

This genus of plants is ranged in the ſecond ſection of Linnæus's twenty-third claſs, which includes the plants which have flowers of different ſexes on the ſame or different plants, which are fruitful.

The Species are,

1. Fraxinus (*Excelſior*) foliolis ſerratis, floribus apetalis. Lin. Sp. Plant. 1057. *Aſh-tree whoſe ſmaller leaves are ſerrated, and flowers having no petals.* Fraxinus excelſior. C. B. P. 416. *The common Aſh.*
2. Fraxinus (*Rotundifolia*) foliolis ovato-lanceolatis ſerratis, floribus coloratis. *Aſh-tree whoſe ſmaller leaves are oval, ſpear-ſhaped, and ſawed, and the flowers coloured.* Fraxinus rotundiore folio. C. B. P. 416. *Aſh-tree with a rounder leaf, commonly called Manna Aſh.*
3. Fraxinus (*Ornus*) foliolis ſerratis, floribus coloratis. Lin. Sp. Plant. 1057. *Aſh-tree whoſe ſmaller leaves are ſawed, and flowers having petals.* Fraxinus humilior ſive altera Theophraſti, minore & tenuiore folio. C. B. P. 416. *Dwarf Aſh of Theophraſtus with ſmaller and narrower leaves.*
4. Fraxinus (*Paniculata*) foliolis lanceolatis glabris, floribus paniculatis terminatricibus. *Aſh-tree with ſmooth ſpear-ſhaped leaves, and flowers growing in panicles at the ends of the branches.* Fraxinus florifera botryoides. Mor. Præl. 265. *The flowering Aſh.*
5. Fraxinus (*Nova Anglia*) foliolis integerrimis, petiolis teretibus. Flor. Virg. 122. *Aſh-tree with the ſmall leaves entire, and taper foot-ſtalks.* Fraxinus ex Novâ Angliâ, pinnis foliorum in mucronem productioribus. Rand. Cat. Hort. Chelſ. *New England Aſh with long acute points to the wings of the leaves.*
6. Fraxinus (*Caroliniana*) integerrimis petiolis teretibus fructu latiore. Prod. Leyd. 533. *Aſh-tree with entire leaves and taper foot-ſtalks.* Fraxinus Caroliniana, latiore fructu. Rand. Cat. H. Chelſ. *Carolina Aſh with a broad fruit.*

The firſt ſort is the common Aſh-tree, which grows naturally in moſt parts of England, and is ſo well known as to need no deſcription. The leaves of this ſort have generally five pair of lobes, and are terminated by an odd one; they are of a very dark green, and their edges are ſlightly ſawed. The flowers are produced in looſe ſpikes from the ſide of the branches, which are ſucceeded by flat ſeeds, which ripen in autumn; there is a variety of this with variegated leaves, which is preſerved in ſome gardens.

The ſecond ſort grows naturally in Calabria, and is generally ſuppoſed to be the tree from whence the manna is collected, which is an exſudation from the leaves of the tree. The ſhoots of this tree are much ſhorter, and the joints cloſer together than thoſe of the firſt ſort; the ſmall leaves are ſhorter, and deeper ſawed on their edges, and are of a lighter green. The flowers come out from the ſide of the branches, which are of a purple colour, and appear in the ſpring before the leaves come out. This tree is of humble growth, ſeldom riſing more than fifteen or ſixteen feet high in England.

The third ſort is a low tree, which riſes about the ſame height as the ſecond; the leaves of this ſort are much ſmaller and narrower than thoſe of the firſt, but are ſawed on their edges, and are of the ſame dark colour. The flowers of this ſort have petals, which are wanting in the common Aſh.

The fourth ſort was raiſed by the late Dr. Uvedale at Enfield, from ſeeds which were brought from Italy by Dr. William Sherard, where the trees grow naturally; but it was ſuppoſed to be a different ſort from that mentioned by Dr. Morriſon, in his Præludia Botanica, but by comparing them together they appear to be the ſame.

The leaves of this ſort have but three or four pair of lobes (or ſmall leaves) which are ſhort, broad, and ſmooth, of a lucid green, and irregularly ſawed on the edges; the midrib of the great leaf is jointed, and ſwelling where the leaves come out. The flowers grow in looſe panicles at the end of the branches; theſe are moſt of them male, having two ſtamina in each, but no germen or ſtyle; they are of a white herbaceous colour, and appear in May. As this ſort very rarely produces ſeeds in England, it is propagated by grafting or budding it upon the common Aſh.

The fifth ſort was raiſed from ſeeds, which were ſent from New England in the year 1724, by Mr. Moore. The leaves of this tree have but three, or at moſt but four pair of lobes (or ſmall leaves) which are placed far diſtant from each other, and are terminated by an odd lobe, which runs out into a very long point; they are of a light green and entire, having no ſerratures on their edges: this tree ſhoots into ſtrong irregular branches, but doth not grow to a large ſize in the trunk. It is propagated by grafting it upon the common Aſh.

The ſixth ſort was raiſed from ſeeds which were ſent from Carolina in the year 1724, by Mr. Cateſby. The leaves of this ſort hath ſeldom more than three pair of lobes, the lower being the leaſt, and the upper the largeſt; theſe are about five inches long and two broad, of a light green colour, and ſlightly ſawed on their edges; the foot-ſtalk, or rather the midrib, of the leaves is taper, and has ſhort downy hairs; the ſeeds are broader than thoſe of the common Aſh, and are of a very light colour. As this ſort hath not yet produced ſeeds in England, it is propagated by grafting it upon the common Aſh.

Theſe trees are now propagated in plenty in the nurſeries for ſale, as there has been of late years a great demand for all the hardy ſorts of trees and ſhrubs, which will live in the open air; but all thoſe trees which are grafted upon the common Aſh, are not ſo valuable as thoſe which are raiſed from ſeeds, becauſe the ſtock grows much faſter than the grafts; ſo that the lower part of the trunk, ſo far as the ſtock riſes, will often be twice the ſize of the upper; and if the trees ſtand much expoſed to the wind, the grafts are frequently broken off to the ſtock, after they are grown to a large ſize, which is a great diſappointment to a perſon after having waited ſeveral years, to ſee their trees ſuddenly deſtroyed. Beſide, if the wood of either of the ſorts is valuable, it can be of little uſe when the trees are ſo raiſed.

The fourth ſort is generally planted for ornament, the flowers making a fine appearance when they are in beauty, for almoſt every branch is terminated by a large looſe panicle; ſo that when the trees are large, and covered with flowers, they are diſtinguiſhable at a great diſtance.

All the other ſorts ſerve to make a variety in plantations, but have little beauty to recommend them; and as their wood ſeems to be greatly inferior to that of the common Aſh, ſo there ſhould be few of theſe planted, becauſe they will only fill up the ſpace where better trees might grow.

The common Aſh propagates itſelf in plenty by the ſeeds which ſcatter in the autumn, ſo that where the ſeeds happen to fall in places where cattle do not come, there will be plenty of the plants come up in the ſpring; but where any perſon is deſirous to raiſe a quantity of the trees, the ſeeds ſhould be ſown as ſoon as they are ripe, and then the plants will come up the following ſpring; but if the ſeeds are kept out of the ground till the ſpring, the plants will not come up till the year after, which is the ſame with all the ſorts of Aſh; that when any of their ſeeds are brought from abroad, as they ſeldom arrive here before the ſpring, the plants muſt not be expected to appear till the next year; therefore the ground ſhould be kept clean all the ſummer where they are ſown, and not diſturbed, leſt the ſeeds ſhould be turned out of the ground, or buried too deep to grow; for many perſons are too impatient to wait a year for the growth of ſeeds, ſo that if they do not come up the firſt year, they dig up the ground, and thereby deſtroy the ſeeds.

When the plants come up, they muſt be kept clean from weeds during the ſummer; and if they make good progreſs in the ſeed-bed, they will be fit to tranſplant by the autumn; therefore there ſhould be ſome ground prepared to receive them, and as ſoon as their leaves begin to fall, they may be tranſplanted. In taking them up, there ſhould be care taken not to break or tear off their roots; to prevent which, they ſhould be taken up with a ſpade, and not dranw up, as is frequently practiſed; for as many of the plants which riſe from ſeeds will out-ſtrip the others in their growth, ſo it is frequently practiſed, to draw up the largeſt plants, and leave the ſmaller to grow a year longer before they are tranſplanted; and to avoid hurting thoſe which are left, the others are drawn out by hand, and thereby many of their roots are torn off or broken; therefore it is much the better way to take all up, little or big together, and tranſplant them out, placing the larger ones together in rows, and the ſmaller by themſelves. The rows ſhould be three feet aſunder, and the plants a foot and a half diſtance in the rows; in this nurſery they may remain two years, by which time they will be ſtrong enough to plant where they are to remain; for the younger they are planted out, the larger they will grow; ſo that where they are deſigned to grow large, they ſhould be planted very young; and the ground where the plants are raiſed, ſhould not be better than that where they are deſigned to grow; for when the plants are raiſed in good land, and afterward tranſplanted into worſe, they very rarely thrive; ſo that it is much the beſt method to make the nurſery upon a part of the ſame land, where the trees are deſigned to be planted, and then a ſufficient number of trees may be left ſtanding upon the ground, and theſe will out-ſtrip thoſe which are removed, and will grow to a larger ſize.

Where people live in the neighbourhood of Aſh-trees, they may ſupply themſelves with plenty of ſelf-ſown plants, provided cattle are not ſuffered to graze on the land, for they will eat off the young plants, and not ſuffer them to grow; but where the ſeeds fall in hedges, or where they are protected by buſhes, the plants will come up and thrive; and in theſe hedges the trees frequently are permitted to grow till they have deſtroyed the hedge, for there is ſcarce any tree ſo hurtful to all kinds of vegetables as the Aſh, which robs every plant of its nouriſhment within the reach of its roots, therefore ſhould never be ſuffered to grow in hedge rows; for they not only kill the hedge, but impoveriſh Corn, or whatſoever is ſown near them. Nor ſhould Aſh-trees be permitted to grow near paſture grounds, for if any of the cows eat of the leaves or ſhoots of the Aſh, all the butter which is made of their milk will be rank and of no value; which is always the quality of the butter which is made about Guildford, Godalmin, and ſome other parts of Surry, where there are Aſh-trees growing about all their paſtures, ſo that it is very rare to meet with any butter in thoſe places which is fit to eat; but in all the good dairy countries, they never ſuffer an Aſh-tree to grow.

If a wood of theſe trees is rightly managed, it will turn greatly to the advantage of its owner; for by the under-wood, which will be fit to cut every ſeven or eight years, for poles or hoops, there will be a continual income more than ſufficient to pay the rent of the ground, and all other charges; and ſtill there will be a ſtock preſerved for timber, which in a few years will be worth forty or fifty ſhillings per tree.

This timber is of excellent uſe to the wheelwright and cartwright, for ploughs, axle-trees, wheel-rings, harrows, bulls, oars, blocks for pullies, and many other purpoſes.

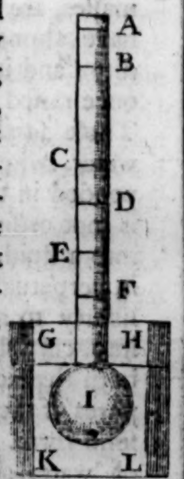
The beſt ſeaſon for felling of theſe trees is from November to February; for if it be done either too early in autumn, or too late in the ſpring, the timber will be ſubject to be infeſted with worms, and other inſects; but for lopping pollards, the ſpring is preferable for all ſoft woods.

FREEZING is the fixing of a fluid, or the depriving it of its natural mobility by the action of cold; or it is the act of converting a fluid ſubſtance into a firm, coherent, rigid one, called ice.

The principal phænomena of freezing are,

1ſt, That Water being dilated or rarefied, and all fluids, oil excepted, i. e. in freezing, take up more ſpace, and are ſpecifically lighter than they were before.

That the bulk and dimenſions of water are increaſed by freezing, is found by many experiments, and it may not be improper here to take notice of the proceſs of nature.



A glaſs veſſel then, I A, full of water to A, being immerged in a veſſel of water mixed with ſalt G H K L, the water preſently riſes from D to C; which ſeems owing to the ſudden conſtriction of the veſſel, haſtily plunged into ſo cold a medium: ſoon after, from the point C, it continually deſcends condenſing, till it arrives at the point F; where, for ſome time, it ſeems to remain at reſt: but it ſoon recovers itſelf, and begins to expand, riſing from F to E, and from thence ſoon after, by one violent leap, mounts to B; and here the water in I is immediately ſeen all thick and cloudy, and, in the very inſtant of this leap, is converted into ice. Add, that while the ice is growing harder, and ſome of the water near the neck of the veſſel I is freezing, the flux of the water is continued above B towards A, and at length runs out at the veſſel.

2dly, That they loſe not only of the ſpecific, but alſo of their abſolute gravity, by freezing; ſo that when they are thawed again, they are found conſiderably lighter than before.

3dly, That frozen water is not quite ſo tranſparent as when it was liquid, and that bodies do not perſpire ſo freely through it.

4thly, That water, when frozen, evaporates almoſt as much as when fluid.

5thly, That water does not freeze in vacuo, but requires the preſence and contiguity of air.

6thly, That water which has been boiled, does not freeze ſo readily as that which has not.

7thly, That water, being covered over with a ſurface of oil of Olives, does not freeze ſo readily as it does without it; and that nut oil abſolutely preſerves it under a ſtrong froſt, when Olive oil will not.

8thly, That ſpirit of wine, nut oil, and oil of turpentine, do not freeze at all.

9thly, That the ſurface of the water, in freezing, appears all wrinkled; the wrinkles being ſometimes in parallel lines, and ſometimes like rays proceeding from a center to the circumference.

The theories of freezing, or the method of accounting for theſe phænomena, are very many.

The chief principles that different authors have gone upon, are, either that ſome foreign matter is introduced within the pores of the fluid, by means of which it is fixed, its bulk increaſed, &c.

Or that ſome matter which was naturally contained in the fluid is now expelled, by reaſon of the abſence of which, the body becomes fixed.

Or that there is ſome alteration produced in the texture or form, either of the particles of the fluid itſelf, or of ſomething that is contained within it.

To ſome one of theſe principles all the ſyſtems of freezing are reducible.

The Carteſians explicate freezing by the receſs or going out of the ethereal matter from the pores of the water, or other liquor; which being once done, the finer parts are too ſmall and flexible to keep the long, ſlender, and eel-like particles of water fluent, or in the form of a liquor.

But the Corpuſcularians, or Gaſſendiſts, aſcribe the freezing of water, with more probability, to the ingreſs of multitudes of cold or frigorific particles, as they call them; which, entering the liquor in ſwarms, and diſperſing themſelves every way through it, croud into the pores of the water, and hinder the wonted agitation of its parts, and wedge it up, as it were, into the hard or conſiſtent body of ice; and from hence proceeds its increaſe of dimenſions, coldneſs, &c.

That ice is ſpecifically lighter than the water out of which it is by freezing made, is certain by its ſwimming in it; and that this lightneſs of ice proceeds from thoſe numerous bubbles which are produced in it by its congelation, is equally plain; but how thoſe bubbles come to be generated in freezing, and what ſubſtance they contain in them, if they are not quite empty, is an inquiry of great importance; and, perhaps, if diſcovered, may contribute much to the underſtanding the nature of cold.

Mr. Hobbes will have it common air, which, intruding into the water in congelation, entangles itſelf with the particles of the fluid, prevents their motion, and produces thoſe numerous bubbles, thus expanding its bulk, and rendering it ſpecifically lighter.

But, in anſwer to this, no ſuch ingreſs of air into water appears in its coagulation; and that it does not get into frozen oil is plain, becauſe that body is condenſed by being frozen.

And Mr. Boyle has alſo ſhewn, by undoubted experiments, that water will freeze in veſſels hermetically ſealed; and in braſs bodies or veſſels cloſely ſtopped, and into which the air can have no ingreſs, hath yet been turned into ice, abounding with theſe bubbles as numerous as thoſe frozen in the open air.

He alſo has proved by experiment, that water kept a while in the exhauſted receiver, till all its bubbles were emerged and gone, being afterwards turned into ice by a freezing mixture, the ice had ſcarce any bubbles in it; whence it is plain, that theſe bubbles are filled with ſome matter which is within the water, if they are filled with any thing. But he proves alſo, by plain experiments, that they have none, or exceedingly little, true elaſtic air contained in them.

Others, and thoſe of the greateſt number, are of opinion, that the freezing matter is a ſalt; and they argue that an exceſs of cold will render water torpid, but never congeal it without ſalt: they ſay that thoſe particles that are the chief cauſe of freezing are ſaline, mixed in a due proportion, congelation bearing a near relation to cryſtallization.

This ſalt is ſuppoſed to be of the nitrous kind, and to be furniſhed by the air, which is generally found to abound in nitre.

It is indeed no difficult matter, to account for the particles of nitre preventing the fluidity of water. Theſe particles are ſuppoſed to be ſo many rigid pointed ſpicula, which are eaſily impelled or driven into the ſtamina or globules of water; which, by this means, becoming variouſly mingled and entangled with it, do, by degrees, weaken and deſtroy the motion of it.

The reaſon that this effect ariſes only in ſevere winter weather, is, that it is then only that the retracting action of the nitrous ſpicula is more than equal to the power or principle by which the fluid is otherwiſe kept in motion, or diſpoſed for motion.

Several experiments of artificial freezing ſupport this opinion.

For if you mix a quantity of common ſaltpetre with ſnow, or ice pulverized, and diſſolve the mixture in the fire, and then immerge a tube full of water in the ſolution; the water, that part of it next the mixture, will freeze preſently, even in a warm air.

Whence they argue, that the ſpicula of the ſalt are driven through the pores of the glaſs, and mixed with the water, by the gravity of the mixture, and of the incumbent air; for that it is evident, that the ſalt has this effect, inaſmuch as it is certainly known, that the particles of water cannot find their way through the pores of the glaſs.

In theſe artificial freezings, in whatever part the mixture is applied, there is preſently a ſkin or lamina of ice produced, whether at the top, bottom, or ſides, by reaſon that there is always a ſtock of ſaline corpuſcles, ſufficient to overpower the particles of fire; but natural congelations are confined to the top of the water, where the laſt moſt abounds.

But this ſyſtem is oppoſed by the author of the Nouvelle Conjecture pour expliquer la Nature de la Glace, who objects, that it does not appear, that the nitre always enters the compoſition of ice; but if it did, it would fall ſhort of accounting for ſome of the principal effects; as,

How ſhould the particles of nitre, by entering the pores of the water, and fixing the parts, cauſe the water to dilate, and render it ſpecifically lighter? They ſhould naturally augment its weight.

This and ſome other difficulties, ſhew the neceſſity of a new theory; and therefore the ingenious author advances this which follows, which ſeems to ſolve the phænomena in a manner that is more eaſy and ſimple, as not depending upon the admiſſion or extruſion of any heterogeneous matter.

The water freezes in the winter only, becauſe its parts, then being more cloſely joined together, mutually embarraſs one another, and loſe all the motion they had; and that the air, or rather an alteration in the ſpring and force of the air, is the cauſe of this cloſer union of water.

It is evident from experiment, that there are an infinite number of particles of groſs air interſperſed among the globules of water; and it is allowed, that each particle of air has the virtue of a ſpring; and hence this author argues, that the ſmall ſprings of groſs air, mixed with water, have more force in cold winter weather, and do then unbend themſelves more, than at other times. Hence thoſe ſprings thus unbending themſelves on one ſide, and the external air continuing to preſs the ſurface of the water on the other, the particles of the water, being thus conſtringed and locked up together, muſt loſe their motion and fluidity, and form a hard, conſiſtent body, till a relaxation of the ſpring of the air, from an increaſe of heat, reduce the particles to their old dimenſions, and leave room for the globules to flow again.

But this ſyſtem ſeems to be built upon a falſe principle, for the ſpring or elaſticity of the air is not increaſed by cold, but diminiſhed; air condenſes by cold, and expands itſelf by heat; and it is demonſtrable in pneumatics, that the elaſtic force of expanded air is to that of the ſame air condenſed, as the bulk when rarefied is to its bulk when condenſed.

Indeed, ſome authors, in order to account for the increaſe of the bulk and dimenſion of the ſpecific gravity of frozen water, have advanced as follows, viz. That the aqueous particles, in their natural ſtate, were nearly cubes, and ſo filled their ſpace without the interpoſition of many pores; but that they are changed from cubes to ſpheres, by congelation; from whence it will neceſſarily follow, that there muſt be a great deal of empty ſpace between them.

But, in oppoſition to this hypotheſis, the nature of fluidity and firmneſs eaſily ſuggeſts, that ſpherical particles are much properer to conſtitute a fluid than cubical ones, and leſs diſpoſed to form a fixed than cubic one.

But after all, in order to come to a conſiſtent theory of freezing, we muſt either have recourſe to the frigorific matter of the Corpuſcularians, conſidered under the new light and advantages of the Newtonian philoſophy, or to the ethereal matter of the Carteſians, under the improvements of Monſ. Gauteron.

The true cauſe of freezing, or the congelation of water into ice, ſay the former, ſeems plainly to be the introduction of the frigorific particles into the pores or interſtices between the particles of the water, and by that means getting ſo near them, as to be juſt within the ſpheres of one another's attracting force, and then they muſt cohere into one ſolid or firm body; but heat afterwards ſeparating them, and putting them into various motions, breaks this union, and ſeparates the particles ſo far from one another, that they get out of the diſtance of the attracting force, and into the verge of the repelling force, and then the water re-aſſumes its fluid form.

Now, that cold and freezing proceed from ſome ſubſtance of a ſaline nature floating in the air, ſeems probable from hence:

That all ſalts, and more eminently ſome particular ones, do prodigiouſly increaſe the force and effects of cold, when mixed with ſnow or ice. It is alſo evident, that all ſaline bodies produce a ſtiffneſs and rigidity in the parts of thoſe bodies into which they enter.

It appears, by microſcopical obſervations upon ſalts, that the figure of ſome ſalts, before they ſhoot into maſſes, are thin, double wedged, like particles which have abundance of ſurface, in reſpect to their ſolidity; and is the reaſon why they ſwim in water, when once raiſed in it, though ſpecifically heavier.

Theſe ſmall points, getting into the pores of the water, whereby they are alſo, in ſome meaſure, ſuſpended in the winter time, when the heat of the ſun is not ordinarily ſtrong enough to diſſolve the ſalts into a fluid, to break their points, and to keep them in perpetual motion, being leſs diſturbed, are at more liberty to approach one another; and, by ſhooting into cryſtals of the form above-mentioned, do, by both their extremities, inſinuate themſelves into the pores of the water, and by that means freeze it into a ſolid form. And it is apparent, that the dimenſions of water are increaſed by freezing, the particles of it being kept at ſome diſtance from one another, by the intervention of the frigorific matter.

But beſides this, there are many little volumes, or ſmall particles of air, included at ſeveral diſtances, both in the pores of the watery particles, and in the interſtices formed by their ſpherical figure. Now, by the inſinuation of the cryſtals, the volumes of air are driven out of the watery particles, and many of them uniting, form larger volumes, which thereby have a greater force to expand themſelves than when they are diſperſed; and ſo both enlarge the dimenſions, and leſſen the ſpecific gravity of water thus congealed into ice.

And hence (ſays Dr. Cheyne, from whom this laſt account is taken) we may gueſs at the manner how water,

ter, impregnated with ſalts, ſulphurs, or earths, which are not eaſily diſſolvable, may form itſelf into metals, minerals, gums, and other foſſils; the parts of theſe mixtures becoming a cement to the particles of water, or getting into their pores, change them into theſe different ſubſtances.

For the ſecond: as an ethereal matter or medium is generally allowed to be the cauſe of the motion of fluids, and as the air itſelf has all its motion from the ſame principle, it follows, that all fluids muſt remain in a ſtate of reſt or fixity, when that matter loſes of its neceſſary force. And conſequently, the air being leſs warmed in the winter time, by reaſon of the obliquity of the ſun's rays, is more denſe and fixed in winter than any other ſeaſon of the year.

But farther: it is evident, from divers experiments, that the air does contain a ſalt which is ſuppoſed to be of the nature of nitre. If this be granted, and the denſity of the air allowed, it will follow, that the particles of this nitre muſt likewiſe be brought nearer together, and thickened by the condenſation of the air; as on the contrary, a rarefaction of the air, and an augmentation of its fluidity, muſt divide and ſeparate them.

And if the ſame happens to all liquors that have imbibed or diſſolved any ſalt, if the warmth of the liquid keep the ſalt exactly divided, and if the coolneſs of a cellar, or of ice, cauſe the particles of the diſſolved ſalt to approach, run into each other, and ſhoot into cryſtals; why ſhould the air, which is allowed to be a fluid, be exempt from the general law of fluids?

It is true, that the nitre of the air, being groſſer in cold weather than in hot, muſt have a leſs velocity; but ſtill the product of its augmented maſs into the velocity that remains, will give it a greater momentum, or quantity of motion. Nor is there any thing farther required to make this ſalt act with greater force againſt the parts of fluids, and this may probably be the cauſe of the great evaporation in froſty weather.

This aereal nitre muſt neceſſarily promote the concretion of liquids; for it is not the air, nor yet the nitre that it contains, which gives the motion to fluids; it is the ethereal medium, therefore a diminution of the motion of reſt ariſes from the diminution of that force.

Now the ethereal matter, which in the winter time is weak enough, muſt ſtill loſe more of its force by its action againſt air condenſed, and loaded with large particles of ſalt. It muſt therefore loſe of its force in cold weather, and become leſs diſpoſed to maintain the motion of the fluids.

In fine, the air, during froſt, may be eſteemed like the ice impregnated with ſalt wherewith liquors are iced in ſummer time. It is very probable that theſe liquors freeze by reaſon of a diminution of the motion of the ethereal medium, by its acting againſt the ice and ſalt together, and the air is not able to prevent its concretion by all its ſcorching heat.

The air (ſays Mr. Boyle) being a fluid as well as water, and impregnated with ſalts of different kinds, it is not improbable, that what happens in water impregnated with ſuch ſalts, may alſo happen in the air. Two proper quantities of different ſalts being diſſolved in hot water, they floated undiſtinguiſhably in it, and retained a capacity to act in conjunction upon ſeveral occaſions; yet when the liquor becomes cold, the ſaline particles of one kind being no longer agitated by a due degree of heat, ſhot into cryſtals; and, loſing their fluidity and motion, viſibly ſeparated themſelves from the other, which ſtill continued fluid in the liquor, and capable of acting ſeparately.

We have divers accounts in the Philoſophical Tranſactions, of a freezing rain which fell in the weſt of England in December 1672. This rain, as ſoon as it touched any thing above the ground, as a bough, or the like, immediately ſettled into ice; and, by multiplying and enlarging the icicles broke all down with its weight; the rain that fell on the ſnow immediately froze into ice, without ſinking into the ſnow at all.

It made an incredible deſtruction of trees beyond any thing in all hiſtory. A certain gentleman weighed a ſprig of an Aſh-tree of juſt three quarters of a pound, the ice which was on it weighed 16 pounds; that ſome perſons were frighted with the noiſe in the air, till they underſtood that it was the clatter of icy boughs daſhed againſt each other.

Dr. Beale remarks, that there was no conſiderable froſt obſerved on the ground during the whole time; whence he concludes, that a froſt may be very fierce and dangerous on the tops of ſome hills and plains, while in other places it keeps at two, three, or four feet diſtance above the ground, rivers, lakes, &c. and may wander about very furious in ſome places, and remiſs in others not far off. The froſt was followed by glowing heats, and a wonderful forwardneſs of flowers and fruits. The effects of freezing vegetables, is farther explained under the article of FROST.

FRITILLARIA. Lin. Gen. Plant. 372. Tourn. Inſt. R. H. 376. tab. 201. Corona Imperialis. Tourn. Inſt. R. H. 372. tab. 197, 198. Fritillary, or Chequered Tulip and Crown Imperial.

The CHARACTERS are,

The flower hath no empalement; it hath ſix oblong petals, is bell-ſhaped, and ſpreading at the baſe; in the hollow, at the baſe of each petal, is ſituated a nectarium; the flower hath ſix ſtamina ſtanding near the ſtyle, which are terminated by oblong four-cornered ſummits. In the center is ſituated an oblong three-cornered germen, ſupporting a ſingle ſtyle which is longer than the ſtamina, crowned by a ſpreading obtuſe ſtigma. The germen afterward becomes an oblong capſule with three lobes having three cells, which are filled with flat ſeeds, ranged in a double order.

The capſule of Fritillaria is oblong and ſmooth, but that of Corona Imperialis hath acute borders, or membranaceous wings.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, which includes the plants which have ſix ſtamina in their flowers, and but one ſtyle.

Theſe two genera of Fritillary and Crown Imperial, have been always ſeparated, till Dr. Linnæus joined them together; indeed by their flowers they may be properly enough placed in the ſame genus; but, if their fruit may be allowed as a characteriſtic note, they ſhould be ſeparate; however, as this new ſyſtem is generally received, I ſhall, in compliance with the preſent taſte, join them together.

The SPECIES are,

1. FRITILLARIA (*Melagris*) foliis linearibus alternis, floribus terminalibus. *Fritillary with narrow leaves placed alternate, and flowers terminating the ſtalk.* Fritillaria præcox, purpurea, variegata. C. B. P. 64. *Early, purple, variegated, chequered Tulip.*
2. FRITILLARIA (*Aquitanica*) foliis infimis oppoſitis. Hort. Cliff. 81. *Fritillary whoſe lower leaves are oppoſite.* Fritillaria Aquitanica, flore luteo obſcuro. Swert. Floril. *Aquitain chequered Tulip, with an obſcure yellow flower.*
3. FRITILLARIA (*Nigra*) floribus adſcendentibus. *Fritillary with flowers growing above each other.* Fritillaria nigra. Lob. Adver. 2. 496. *Black chequered Tulip.*
4. FRITILLARIA (*Lutea*) foliis lanceolatis, caule unifloro maximo. *Fritillary with ſpear-ſhaped leaves, and one large flower on each ſtalk.* Fritillaria lutea maxima Italica. Park. Parad. 43. *Largeſt yellow Italian Fritillary.*
5. FRITILLARIA (*Umbellata*) floribus umbellatis. *Fritillary with flowers growing in umbels.* Fritillaria umbellifera. C. B. P. 64. *Umbellated chequered Tulip.*
6. FRITILLARIA (*Perſica*) racemo nudiuſculo, foliis obliquis. Hort. Upſal. 82. *Fritillary with a naked ſpike of flowers and oblique leaves.* Lilium Perſicum. Dod. Pempt. 220. *The Perſian Lily.*
7. FRITILLARIA (*Racemoſa*) floribus racemoſis. *Fritillary with flowers growing in bunches.* Fritillaria ramoſa, ſeu lilium Perſicum minus. Mor. Hort. Reg. Bleſ. *Branching Fritillary, or ſmaller Perſian Lily.*

8. Fritillaria (*Imperialis*) racemo comoſo infernè nudo, foliis integerrimis. Lin. Hort. Upſal. 82. *Fritillary with a tufted bunch of leaves over the flowers, which is naked below, and entire leaves.* Corona Imperialis. Dod. Pempt. 202. *Crown Imperial.*

9. Fritillaria (*Regia*) racemo comoſo infernè nudo, foliis crenatis. Lin. Sp. Plant. 303. *Fritillary with a tufted bunch of leaves over the flowers, which is naked below, and crenated leaves.* Corona regalis lilii folio crenato. Hort. Elth. 110. *Royal Crown with a crenated Lily leaf.*

10. Fritillaria (*Autumnalis*) racemo infernè nudo, foliis oblongis mucronatis. *Fritillary with a naked ſtalk, and oblong pointed leaves.*

The firſt ſort grows naturally in Italy, and other warm parts of Europe; and from the ſeeds of this there have been great varieties raiſed in the gardens of the floriſts, which differ in the ſize and colour of their flowers; and as there are frequently new varieties produced, ſo it would be to little purpoſe to enumerate thoſe which are at preſent in the Engliſh and Dutch gardens, which amount to a great number in the catalogues of the Dutch floriſts, who are very fond of any little diſtinction, either in the colour or ſhape, to enlarge their liſts.

The ſorts which are here enumerated, I think may be allowed as diſtinct ſpecies, notwithſtanding Dr. Linnæus has reduced them to five; for I have raiſed many of all the ſorts from ſeed, which have conſtantly produced the ſame as the ſeeds were taken from, and have only differed in the colour or ſize of the flowers; for the ſort with broad leaves produced the ſame ſort again, and the umbellated and ſpiked ſorts produced the ſame, though there are ſeveral varieties in the colours of their flowers.

The firſt hath a round compreſſed root, in ſhape like that of Cornflag, but is of a yellowiſh white colour; the ſtalk riſes about fifteen inches high, having three or four narrow long leaves placed alternately, and the top is divided into two ſlender foot-ſtalks which turn downward, each ſuſtaining one bell-ſhaped inverted flower, compoſed of ſix petals, which are chequered with purple and white like a cheſs-board; and in the center is ſituated a germen ſupporting one ſtyle, crowned by a trifid ſtigma; the ſix ſtamina ſtand about the ſtyle, but are ſhorter. At the bottom of each petal there is a cavity, in which is ſituated a nectarium, filled with a ſweet liquor; after the flower is fallen, the germen ſwells to a pretty large three-cornered blunt capſule, and then the foot-ſtalk is turned and ſtands erect; when the ſeeds are ripe, the capſule opens in three parts and lets out the flat ſeeds, which were ranged in a double order. The flowers of this appear the latter end of March or beginning of April, and the ſeeds are ripe in July. There is a variety of this with a double flower.

The ſecond ſort grows naturally in France; the leaves of this are broader, and of a deeper green than the former; the lower leaves are placed oppoſite, but thoſe above are alternate; the ſtalk riſes a foot and a half high, and is terminated by two flowers of an obſcure yellow colour, which ſpread more at the brim than thoſe of the firſt ſort, but are turned downward in the ſame manner. This flowers three weeks after the firſt. There is a variety of this with greeniſh flowers, which grows naturally in ſome parts of England.

The third ſort ſeldom riſes more than a foot high, the leaves are narrow like thoſe of the firſt ſort, but are ſhorter; each ſtalk is terminated by three or four flowers, which ariſe above each other; they are of a very dark purple, chequered with yellowiſh ſpots. This flowers in April, about the ſame time with the ſecond.

The fourth ſort riſes about a foot high, the ſtalk is garniſhed with ſpear-ſhaped leaves four inches long and one broad, of a graſs-green colour; theſe are ſometimes placed oppoſite, but are generally alternate; the ſtalk is terminated by one large bell-ſhaped flower of a yellowiſh colour, chequered with light purple. This ſort flowers about the ſame time as the firſt. There are two or three varieties of this, which differ in the ſize and colour of their flowers and the breadth of their leaves, but retain their ſpecific difference, ſo as to be eaſily diſtinguiſhed from the other ſorts.

The fifth ſort riſes a foot and a half high; the ſtalk is garniſhed with ſhorter and broader leaves than the firſt ſort, which are of a grayiſh colour; the flowers are produced round the ſtalks like thoſe of the Crown Imperial; they are of a dark purple colour, chequered with a yellowiſh green. This flowers about the ſame time with the ſecond ſort.

The ſixth ſort is commonly called the Perſian Lily, and is ſuppoſed to grow naturally in Perſia, but has been long cultivated in the Engliſh gardens; the root of this ſort is round and large, the ſtalk riſes three feet high; the lower part of it is cloſely garniſhed with leaves which are three inches long, and half an inch broad, of a gray colour, ſtanding on every ſide of the ſtalks, but are twiſted obliquely; the flowers grow in a looſe ſpike at the top of the ſtalk, forming a pyramid; they are ſhaped like thoſe of the other ſpecies, but are much ſhorter, and ſpread wider at their brims, and are not bent downward like thoſe. They are of a dark purple colour, and appear in May, but are ſeldom ſucceeded by ſeeds in England, ſo are only propagated by offſets.

The ſeventh ſort hath a much ſhorter ſtalk than the laſt, but is garniſhed with leaves like thoſe, only they are ſmaller; the ſtalks branch out at the top into ſeveral ſmall foot-ſtalks, each ſuſtaining one dark coloured flower. This is commonly called the ſmall Perſian Lily, from its reſemblance to the former ſort.

Theſe plants are propagated either by ſeeds, or offſets from the old roots; by the firſt of which methods new varieties will be obtained, as alſo a larger ſtock of roots in three years, than can be obtained in twenty or thirty years in the latter method: I ſhall therefore firſt treat of their propagation by ſeeds.

Having provided yourſelf with ſome good ſeeds, ſaved from the faireſt flowers, you muſt procure ſome ſhallow pans or boxes, which muſt have ſome holes in their bottoms to let out the moiſture; theſe you ſhould fill with light freſh earth, laying a few potſheards over the holes, to prevent the earth from ſtopping them; then, having laid the earth very level in the boxes, &c. you muſt ſow the ſeeds thereon pretty thick, covering it with fine ſifted earth a quarter of an inch thick. The time for ſowing the ſeed is about the beginning of Auguſt, for if it be kept much longer out of the ground it will not grow; then place the boxes or pans where they may have the morning ſun until eleven o'clock, obſerving, if the ſeaſon proves dry, to water them gently, as alſo to pull up all weeds as ſoon as they appear; for if they are ſuffered to remain until they have taken deep root into the earth, they would draw the ſeeds out of the ground whenever they are pulled up. Toward the latter end of September you ſhould remove the boxes, &c. into a warmer ſituation, placing them cloſe to a hedge or wall expoſed to the ſouth; if they are ſown in pots, theſe ſhould be plunged into the ground, but they are beſt in tubs; theſe ſhould be covered in ſevere froſt. In this ſituation they may remain until the middle of March, by which time the plants will be come up an inch high; you muſt therefore remove the boxes, as the weather increaſes hot, into a more ſhady ſituation; for while the plants are young, they are liable to ſuffer by being too much expoſed to the ſun: and in this ſhady ſituation they may remain during the heat of the ſummer, obſerving to keep them clear from weeds, and to refreſh them now and then with a little moiſture; but be careful not to give them much water after their leaves are decayed, which would rot their roots. About the beginning of Auguſt, if the roots are very thick in the boxes, you ſhould prepare a bed of good light freſh earth, which muſt be levelled very even, upon which you ſhould ſpread the earth in the boxes in which the ſmall roots are contained, equally covering it about one fourth of an inch thick with the ſame freſh earth: this bed ſhould be ſituated in a warm poſition, but not too cloſe to hedges, walls, or pales, which would cauſe their leaves to be long and ſlender, and make the roots weaker than if placed in a more open expoſure.

In this bed they may remain until they flower, which is generally the third year from ſowing; at which time you ſhould put down a mark to the roots of all ſuch as produce fair flowers, that at the time of taking them out of the ground (which ought to be ſoon after their green leaves are decayed) they may be ſelected into a bed amongſt your old roots of this flower, which, for their beauty, are preſerved in the beſt gardens; but the other leſs valuable flowers may be planted in the borders of the parterre-garden for their variety, where, being intermixed with other flowers of different ſeaſons, they will make a good appearance.

The fine ſorts of this flower ſhould remain undiſturbed three years, by which time they will have produced many offſets; and ſhould be taken up when their leaves are decayed, and planted into a freſh bed, taking ſuch of their offſets as are large enough to produce flowers to plant in the flower-garden; but the ſmaller roots may be planted into a nurſery-bed, until they have obtained ſtrength enough to flower; but you muſt never ſuffer theſe roots to lie out of the ground when you remove them, but plant them again immediately, otherwiſe they will periſh.

During theſe three years which I have adviſed the roots to remain in the beds, the ſurface of the earth ſhould be ſtirred every autumn with a trowel, obſerving not to go ſo deep as to bruiſe the root, and at the ſame time lay a thin cover of very rotten dung or tanners bark upon the ſurface of the beds; which, being waſhed into the ground, will cauſe the flowers to be larger, as alſo the roots to make a greater increaſe: you muſt alſo obſerve to keep them conſtantly clear from weeds, and thoſe roots which you would preſerve with care, ſhould not be ſuffered to ſeed.

When a ſtock of good flowers are obtained, they may be preſerved and increaſed in the ſame manner as other bulbous rooted flowers, which is by offſets ſent out from their roots, which ſhould be taken off every other year from the fineſt ſorts; but the ordinary flowers may remain three years undiſturbed, in which time they will have multiplied ſo much, as that each root will have formed a cluſter; ſo that if they are left longer together, the roots will be ſmall, and the flowers very weak; therefore, if theſe are taken up every other year, the roots will be the ſtronger. Theſe roots may be treated in the ſame manner as Tulips, and other bulbous rooted flowers, with this difference only, that the roots will not bear to be kept out of the ground ſo long; therefore, if there ſhould be a neceſſity for keeping them out of the ground any time, it will be beſt to put the roots into ſand to prevent their ſhrinking.

As theſe flowers come out early in the ſpring, they make a pretty appearance in the borders of the pleaſure-garden, where they are planted in ſmall clumps; for when they ſtand ſingle in the borders, they make but a poor figure.

The eighth ſort is the Crown Imperial, which is now very common in the Engliſh gardens. This grows naturally in Perſia, from whence it was firſt brought to Conſtantinople, and about the year 1570, was introduced to theſe parts of Europe; of this flower there are a great variety now preſerved in the gardens of floriſts, but as they have been produced accidentally from ſeeds, they are but one ſpecies; however, for the ſatisfaction of the curious, I ſhall here mention all the varieties which have come to my knowledge.

1. The common Crown Imperial; this is of a dirty red colour.
2. The yellow Crown Imperial; this is of a bright yellow.
3. The bright red Crown Imperial, called Fuſal.
4. The pale yellow Crown Imperial.
5. The yellow ſtriped Crown Imperial.
6. The large flowering Crown Imperial.
7. The broad leaved late red Crown Imperial.
8. The double and triple crowned Imperial Crown.
9. The double red Crown Imperial.
10. The double yellow Crown Imperial.
11. The ſilver ſtriped leaved Crown Imperial.
12. The yellow ſtriped leaved Crown Imperial.

There are ſome few other varieties which are mentioned in the catalogues of the Dutch floriſts, but their diſtinctions are ſo minute, that they are not diſtinguiſhable, ſo I ſhall paſs them over, as thoſe here inſerted are all that I have ſeen growing either in England or Holland, which deſerved any diſtinction.

The Crown Imperial hath a large round ſcaly root of a yellow colour, and a ſtrong odour of a fox; the ſtalk riſes to the height of four feet or upward; it is ſtrong, ſucculent, and garniſhed two-thirds of the length on every ſide, with long narrow leaves ending in points, which are ſmooth and entire; the upper part of the ſtalk is naked, a foot in length; then the flowers come out all round the ſtalk upon ſhort foot-ſtalks, which turn downward, each ſuſtaining one large, ſpreading, bell-ſhaped flower, compoſed of ſix ſpear-ſhaped petals; at the baſe of each petal is a pretty large cavity, in which is ſituated a large white nectarium, filled with a mellous liquor. In the center of the flower is fixed a three-cornered oblong germen, upon which reſts the ſingle ſtyle, which is the length of the petals, and is crowned by a ſpreading obtuſe ſtigma; round the ſtyle there are ſix awl-ſhaped ſtamina which are ſhorter than the ſtyle, and are terminated by oblong four-cornered ſummits. Theſe flowers hang downward, and above them riſes a ſpreading tuft of green leaves, which are erect, and from between theſe come out the foot-ſtalks of the flowers: when the flowers decay, the germen ſwells to a large hexagonal capſule, ſhaped like a water-mill, having ſix cells, which are filled with flat ſeeds. This plant flowers the beginning of April, and the ſeeds are ripe in July.

The ſort with yellow flowers, that with large flowers, and thoſe with double flowers, are the moſt valuable; but that which hath two or three whorls of flowers above each other, makes the fineſt appearance; though this ſeldom produces its flowers after this manner the firſt year after removing, but the ſecond and third year after planting, the ſtalks will be taller, and frequently have three tier of flowers, one above another, which is called the Triple Crown. The ſtalks of this ſort frequently run flat and broad, when they produce a greater number of flowers than uſual; but this is only a luxuriancy of nature, not conſtant; though many of the writers have mentioned it as a particular variety.

As this is one of the earlieſt tall flowers of the ſpring, it makes a fine appearance in the middle of large borders, at a ſeaſon when ſuch flowers are much wanted to decorate the pleaſure-garden: but the rank fox-like odour which they emit, is too ſtrong for moſt people, ſo hath rendered the flowers leſs valuable than they would have been; for there is ſomething very pleaſing in the ſight of them at a diſtance, ſo that were it not for the offenſive ſmell of the leaves and flowers, it would be more frequently ſeen in all gardens for pleaſure.

This may be propagated by ſeeds, or offſets from the root; the firſt is too tedious for moſt of the Engliſh floriſts, becauſe the plants ſo raiſed, are ſix or ſeven years before they flower; but the Dutch and Flemiſh gardeners, who have more patience, frequently raiſe them from ſeeds, ſo get ſome new varieties, which rewards their labour. The method of propagating theſe flowers from ſeeds, being nearly the ſame as for the Tulip, the reader is deſired to turn to that article, where there are full directions for performing it.

The common method of propagating them here, is by offſets ſent out from the old roots, which will flower ſtrong the ſecond year after they are taken from the roots; but in order to have plenty of theſe, the roots ſhould not be tranſplanted oftener than every third year, by which time each root will have put out ſeveral offſets, ſome of which will be large enough to flower the following year, ſo may be planted in the borders of the flower-garden, where they are to remain; and the ſmaller roots may be planted in a nurſery-bed, to grow a year or two according to their ſize; therefore they ſhould be ſorted, and the ſmalleſt roots planted in a bed together, which ſhould remain there two years, and the larger by themſelves to ſtand one year, by which time they will have acquired ſtrength enough to flower, ſo may then be removed into the pleaſure-garden.

The time for taking up theſe roots is in the beginning of July, when their ſtalks will be decayed; and they may be kept out of the ground two months, but they ſhould be laid ſingle in a dry ſhady room, but not in heaps, or in a moiſt place, which will cauſe them to grow mouldy and rot. The offſets ſhould be firſt planted, for as theſe are ſmall, they will be apt to ſhrink if they are kept long out of the ground.

As the roots are large, they muſt not be planted too near other flowers; and when they are planted in beds by themſelves, they ſhould not be nearer than a foot and a half in the rows, and two feet row from row; they ſhould be planted ſix inches deep at leaſt, eſpecially the ſtrong roots: they delight in a light ſoil, not too wet, nor very full of dung; therefore, if any dung is laid upon the borders where they are planted, it ſhould be buried pretty deep, ſo as to be two or three inches below the roots.

The ninth and tenth ſorts grow naturally at the Cape of Good Hope, from whence they were brought into the European gardens. The ninth has been many years an inhabitant, where it has been uſually titled Corona Regalis. This has a tuberoſe root, from which ariſe in the autumn ſix or eight obtuſe leaves, near five inches long and two broad toward the top, growing narrower at their baſe, and are crenated on their borders, lying flat on the ground; theſe continue all the winter: in the ſpring ariſes the flower-ſtalk in the center of the leaves, about ſix inches high, naked at the bottom; but the upper part is ſurrounded by bell-ſhaped flowers, compoſed of ſix greeniſh petals, with an oval germen ſituate at the bottom, ſurrounded by ſix ſtamina, ſupporting a triangular ſtyle, crowned by a trifid ſtigma; the germen afterwards becomes a roundiſh capſule, but rarely perfects ſeeds in England. This flowers in April, and the leaves decay in June.

The ſecond ſort I raiſed from ſeeds, which were ſent me from the Cape of Good Hope: the root of this is like that of the ninth ſort, but the leaves are more than a foot long, broad at their baſe, but are narrowed to the top, where they end in acute points; the flower-ſtalk riſes rather higher than that of the ninth, but the flowers are of the ſame ſhape and colour: this ſeldom flowers till Auguſt. The roots of this ſort were ſtolen out of the Chelſea garden the following ſpring after it had flowered, and were ſold to ſome perſons whoſe love for rare plants exceeded their honeſty.

FRITILLARIA CRASSA. See Asclepias.

FRONDOSE [frondoſus, *Lat.*] full of leaves, or ſhoots.

FROST may be defined to be an exceſſive cold ſtate of the weather; whereby the motion and fluidity of the liquors are ſuſpended; or, it is that ſtate of the air, &c. whereby fluids are converted into ice.

By froſt metals contract, or are ſhortened. Monſ. Auzout found by an experiment, that an iron tube twelve feet long, upon being expoſed to the air in a froſty night, loſt two lines of its length; but this may be ſuppoſed to be wholly the effect of cold.

On the contrary, froſt does not contract fluids, but, on the other hand, ſwells or dilates them near one tenth of their bulk.

Mr. Boyle gives us ſeveral experiments of veſſels made of metals exceeding thick and ſtrong, which being filled with water, cloſe ſtopped, and expoſed to the cold, the water, being expanded by freezing, and not finding either room or vent, burſt the veſſels.

A ſtrong barrel of a gun, with water in it, being ſtopped cloſe, and frozen, was rent the whole length; and a ſmall braſs veſſel, five inches deep, and two in diameter, filled with water, &c. and frozen, lifted up its lid, which was preſſed with a weight of fifty-ſix pounds.

There are alſo related many remarkable effects of froſt on vegetables. Morery, Hiſt. de France, ſays, That trees are frequently ſcorched and burnt up with froſt, as with the moſt exceſſive heat, and that even in ſo warm a climate as Provence.

Mr. Bobart relates, That in the great froſt anno 1683, Oaks, Aſhes, Walnut-trees, &c. were miſerably ſplit and cleſt, ſo as they might be ſeen through; and this too with terrible noiſes like the exploſion of fire arms; that the clifts were not only in the bodies, but continued to the larger boughs, roots, &c. Philoſ. Tranſact. N° 105.

Dr. Derham ſays, That the froſt in 1708, was remarkable through the greateſt part of Europe; and the greateſt in degree, if not the moſt univerſal, in the memory of man; that it extended throughout England, France, Germany, Denmark, Italy, &c. but was ſcarce felt in Scotland and Ireland. All the Orange-trees and Olives in Italy, Provence, &c. and all the Walnut-trees throughout France, with an infinity of other trees, periſhed by the froſt.

Monſ. Gouteron ſays, They had a gangrene on them, which he takes to be the effect of a corroſive ſalt, which corrupted and deſtroyed their texture. He adds, That there is ſo much reſemblance between the gangrene befalling plants through froſt, and that which the parts of animals are liable to, that they muſt have ſome analogous cauſe. Corroſive humours burn the parts of animals, and the aëreal nitre, condenſed, has the ſame effects on the parts of plants. Memoires de l' Academie Royale de Sciences, an. 1709.

Dr. Derham ſays, That the greateſt ſufferers in the animal kingdom were birds and inſects, but vegetables were much the greateſt ſufferers; that few of the tender ſorts of vegetables eſcaped the ſeverity of the froſt; Bays, Laurels, Roſemary, Cypreſs, Alaternuſes, Phillyreas, Arbutuſes, Lauruſtinuſes, and even Furz, with moſt ſort of the fruteſcent herbs, as Lavenders, Abrotanums, Rue, Thyme, &c. were generally deſtroyed. He adds, that the ſap of the finer wall-fruit was ſo congealed and deſtroyed, that it ſtagnated in the limbs and branches, and produced diſorders like to chilblains in human bodies, which would turn to mortifications in many parts of the trees; that the very buds of the finer trees, both in the leaf, buds, and bloſſom buds, were quite killed, and dried into a farinacious matter.

Dr. Derham relates it as a common obſervation, That vegetables ſuffered more from the ſun than from the froſt, in that the ſun-ſhine, melting the ſnow, and opening the ground, left it more expoſed to the rigour of the enſuing night. It was likewiſe obſerved, at a meeting of the Royal Society, That the calamities which befel trees, aroſe not purely from their being frozen, but principally from the winds ſhaking and rocking them when they are frozen, which rent and parted their fibres. Philoſ. Tranſact. N° 324.

Hoar froſt, or white froſt, is the dew frozen, or congealed early in cold mornings, chiefly in autumn. This (as Mr. Regis obſerves) is an aſſemblage of little parcels of ice or cryſtals, which are of various figures, according to the diſpoſition of the vapours which meet and are condenſed by cold.

Dew is, to all appearance, the matter of hoar froſt, though many of the Carteſians ſuppoſe it to be formed of a cloud, and either congealed in the cloud, and ſo let fall, or ready to be congealed as ſoon as it arrives at the earth.

In the year 1728-9, there was a remakable froſt, which continued for ſome months, and deſtroyed a great number of trees and plants in ſeveral parts of Europe, a brief account of which may not be improper to be here inſerted.

The autumn began with cold north and eaſt winds, and early in November the nights were generally froſty, though the froſt did not enter the ground deeper than the ſun thawed the following day; but toward the end of November the winds blew extremely cold from the north, which was ſucceeded by a great ſnow, which fell in ſuch quantities in one night, as to break off large arms, as alſo the tops of many Evergreen-trees, on which it lodged. After the ſnow had fallen, it began to freeze again, the wind continuing to blow from the north; the days were dark and cloudy for ſome time, but afterwards it cleared up, and the ſun appeared almoſt every day, which melted the ſnow where expoſed to it, whereby the froſt penetrated deeper into the ground. It was obſervable, that, during theſe clear days, a great miſt or vapour, appeared in the evenings, floating near the ſurface of the ground until the cold of the night came on, when it was ſuddenly condenſed, and diſappeared. About the 8th of December, the nights were extremely cold; the ſpirits in the thermomoter fell 18 degrees below the freezing point, and on the 10th of the ſame month the froſt was as ſevere as had been known in the memory of man; the ſpirits of the thermometer fell to 20 degrees below the freezing point. At this time vaſt numbers of Lauruſtinuſes, Phillyreas, Alaternuſes, Roſemary, Arbutus, and other Evergreen-trees and ſhrubs began to ſuffer; eſpecially ſuch as had been trimmed up to heads with naked ſtems, or had been clipped late in autumn. At this time alſo there were great numbers of large deciduous trees diſbarked by the froſt, as Pear-trees, Plane-trees, Walnut-trees, with many other ſorts, and it was chiefly on the weſt and ſouth-weſt ſide of the trees, that the bark came off.

About the middle of December the froſt abated of its intenſeneſs, and ſeemed to be at a ſtand till the 23d of the ſame month, when the wind blew extremely ſharp and cold from the eaſt, and the froſt increaſed again, continuing very ſharp till the 28th day, when it began to abate again, and ſeemed to be going off, the wind changing to the ſouth; but it did not continue long in this point, before it changed to the eaſt again, and the froſt returned, though it was not ſo violent as before.

Thus the weather continued for the moſt part froſty, till the middle of March, with a few intervals of mild weather, which brought forward ſome of the early flowers; but the cold returning, ſoon deſtroyed them: ſo that thoſe plants which uſually flower in January and February, did not this year appear till March, and before they were fully blown, were cut off by the froſt; of this number were all the Spring Crocuſes, Hepaticas, Perſian Iriſes, Black Hellebores, Mezereons, with ſome others.

The Cauliflower plants, which were planted out of the beds in the open ground, during the intervals between the froſt, were moſt of them deſtroyed, or ſo much cut, that they loſt moſt of their leaves; the early Beans and Peas were moſt of them killed, and many fruit and foreſt trees, which had been lately removed, were quite deſtroyed. The loſs was very great to ſome curious perſons, who had been many years endeavouring to naturalize great numbers of exotic trees and ſhrubs, abundance of which were either totally killed, or deſtroyed to the ſurface of the ground; amongſt this number there were many ſorts deſtroyed, which had endured the open air many years, without receiving the leaſt injury from the cold, ſuch as Paſſion Flowers, Cork-trees, Ciſtuſes, Roſemary, Stœchas, Sage, Maſtich, and ſome others. In ſome places the young Aſh and Walnut-trees were killed; but when the froſt went off, there appeared to have been much more damage done in the gardens, than there really was, which occaſioned many people to dig up and deſtroy large quantities of trees and ſhrubs, which they ſuppoſed were killed; whereas thoſe who had more patience, and ſuffered them to remain, fared better; for great numbers of them ſhot out again, ſome from their ſtems and branches, and others from their roots, the following ſummer.

Nor was the froſt more ſevere in England, than in other parts of Europe; but, on the contrary, in compariſon, favourable; for in the ſouthern parts of France, the Olives, Myrtles, Ciſtuſes, Alaternuſes, and ſeveral other trees and ſhrubs, which grow there almoſt ſpontaneouſly, were either deſtroyed, or at leaſt were killed to their roots; and about Paris, and the northern parts of France, the buds of their fruit-trees were deſtroyed, although they remained cloſed, ſo that there were very few bloſſoms which opened that ſpring. The Fig-trees were in ſeveral parts of France quite killed, and in England their tender branches were deſtroyed, ſo that there was very little fruit on thoſe trees the following ſummer, except where they were protected from the froſt.

In Holland the Pines and Firs, with ſeveral other trees, which are natives of cold countries, were greatly injured by the cold; and moſt of the trees and ſhrubs, which were brought from Italy, Spain, or the ſouth parts of France, which had been planted in the full ground, in that country, were entirely killed, though many other ſorts, which had been brought from Virginia and Carolina, eſcaped very well in the ſame gardens; but the perſon who ſuffered moſt in that country, was the learned Dr. Boerhaave, who had been ſeveral years endeavouring to naturalize as many exotic trees and ſhrubs as he could poſſibly obtain from the ſeveral parts of the world, great numbers of which were entirely deſtroyed by the froſt this winter.

In ſome parts of Scotland they not only loſt many of their curious flowers, plants, and trees, but great numbers of ſheep, and other cattle, were buried under the ſnow, where they periſhed; and many poor people, who went to look after their cattle, were equal ſufferers with them, being buried in the ſnow, which in ſome places fell eight or nine feet deep in one night.

It has been obſerved by thermometers, when that kind of hovering lambent fog ariſes (either mornings or evenings) which frequently betokens fair weather, that the air, which in the preceding day was much warmer, has, upon the abſence of the ſun become many degrees cooler than the ſurface of the earth, which being near 1500 times denſer than the air, cannot be ſo ſoon affected with the alteration of heat and cold; whence it is probable, that thoſe vapours which are raiſed by the warmth of the earth, are by the cooler air ſoon condenſed into a viſible form. The ſame difference has been obſerved between the coolneſs of the air, and the warmth of water in a pond, by putting a thermometer, which hung all night in the open air in ſummer time, into the water, juſt before the riſing of the ſun, when the like reek, or fog, was riſing on the ſurface of the water.

In the year 1739-40, we had another ſevere winter, which did great miſchief to the gardens, fields, and woods, the effects of which are yet, and will be many years, felt in Europe. Some particulars of theſe depredations, may not, perhaps, be unacceptable to the reader, if they are here mentioned.

The wind ſet in blowing from the north and north-eaſt, about the autumnal equinox, and continued to blow from the ſame quarter, with little variation, upward of ſix months. Early in November, there was a continued ſharp froſt for nine days, in which time the ice upon large ponds, and other ſtanding waters, was frozen ſo hard as to bear perſons who ſkated thereon; but toward the end of November the froſt abated, and there was little more than ſlight morning froſts until Chriſtmas day, when it froze pretty hard that morning, and continued every morning ſo to do; but on the 28th day of December, the wind blew with great ſtrength from the north-eaſt, and brought on ſevere cold; that night the froſt penetrated very deep into the ground, and the next day, viz. the 29th, the wind changed to the ſouthward of the eaſt, and blew with great fury; the thermometer fell this day to twenty-five degrees below froſt; in the morning ſome little ſnow fell, but the violence of the wind carried it off; but cold ſtill increaſing, the waters were all frozen over, and that day it was ſo intenſe, as to freeze the water of the river, which was raiſed by the force of the wind into ice, before it fell down again. The wind continued to blow with the ſame force, and from the ſame quarter, all the 30th day, the cold ſtill increaſing, ſo that at this time the froſt penetrated into moſt of the green-houſes in England, but eſpecially into all thoſe whoſe fronts had the leaſt inclination to the eaſt; and ſuch of them as fronted the ſouth-weſt eſcaped beſt, where the back walls were of a ſufficient thickneſs to keep out the froſt; the ſpirits in the thermometer fell in the night of the 30th day to thirty-two degrees below the freezing point, which was lower than it had been known in England before; the violence of the wind made it very troubleſome for perſons of the moſt robuſt conſtitutions to be abroad, and this alſo cauſed the froſt to penetrate through thick walls, and in the ſpace of two days, the Evergreen-trees and ſhrubs appeared as if they had been ſcorched by fire, ſo that they ſeemed to have no life; the only trees of all the ſorts of Evergreens which retained their verdure at this time, were the Portugal Laurel, Savin, and ſhrubby Hartwood; theſe in the midſt of this ſevere froſt remained unhurt, when all the others were as brown as if they had been dead a year; and it was very late in the ſpring, before any of them reſumed their uſual verdure: during theſe ſevere days there had but little ſnow fallen, ſo that the froſt penetrated deep in the ground, and deſtroyed the roots of great part of the vegetables, where they were not well ſecured; the Artichoke roots were moſt of them killed in all the kitchen-gardens, ſome few only eſcaped, theſe were ſuch as were not intended to be preſerved. A ſingle row of theſe roots, which were growing in a place where a great quantity of dung had been wheeled over them, whereby the ground was rendered as hard as that of a common foot-way, though there was no covering upon theſe roots, yet they ſurvived the froſt and did well; another parcel which was growing near a tan-yard, where, by accident, ſome tan had been thrown, were preſerved, ſo that from ſome of theſe accidents we were ſo lucky as to retrieve the good kind of Artichoke, which the Engliſh gardens were ſo famous for being ſtocked with.

By the ſharp piercing winds the Graſs was almoſt totally burned up, ſo that there was not the leaſt verdure to be ſeen in the fields, and in many places the ſweeteſt and beſt kinds of the herbage were entirely killed, ſo that there remained only the ſtrong rough kinds of graſs, whereby the paſtures were in general much damaged; but on the 31ſt day in the evening, the wind being much abated, the ſeverity of the froſt was not ſo great, and there ſeemed an appearance of a thaw on the firſt and ſecond of January, but on the third in the evening the froſt ſet in again with great violence; and on the fourth of January in the morning, the thermometer was fallen one degree lower than it had been before. The ſame morning there was the greateſt hoary froſt which had been ſeen, the woods, trees, and hedges, appeared as if they had been covered with ſnow; and although there was no wind ſtirring, yet the air was ſo ſharp and penetrating, as to render it difficult to endure the cold, even with great exerciſe.

The timber-trees ſuffered greatly that morning, eſpecially the Oaks, which were ſplit with great violence; and the noiſe in the woods that morning, reſembled that of great branches breaking down in every part of the woods, and when heard at a diſtance, like the firing of guns. This was little attended to at the time, but the timber which has been ſince fallen, ſufficiently proves the great damage which the woods then ſuſtained; nor was it here the calamity ſtopped, for the Oaks in general had received ſo much injury from the froſt, as to occaſion ſuch a weakneſs and diſtemper among them, that the following ſpring they were infeſted with inſects to ſuch a degree, as that their leaves were eaten and entirely deſtroyed by them; ſo that at Midſummer the trees were as naked as if it had been the beginning of April; and this diſtemper continued for two years after, almoſt as bad as at firſt, and has leſſened by degrees, as the trees have recovered their ſtrength; and where the trees were old and weak, they have not yet gotten the better of this diſtemper.

The herbage was alſo ſo much weakened by the ſeverity of the froſt, as not to be able to reſiſt the attack made upon it by inſects, ſo that innumerable quantities of them were diſcovered in the paſtures in many parts of Europe, beginning firſt in the northern countries, and afterward ſpreading to the ſouth; and theſe inſects in many places were ſo numerous, as to deſtroy the ſward of Graſs, and it is to be feared the diſtemper which ſo long raged among the cattle may have been owing to this cauſe; for wherever the diſtemper ſpread, it has been obſerved, that numbers of theſe inſects have harboured about the roots of the Graſs: and as a farther proof of this, it has conſtantly been remarked, that, when theſe grubs are changed into a ſort of beetle, and take their flight (which is commonly about the beginning of May,) the diſtemper ceaſes; and when theſe beetles have depoſited their eggs in autumn, the diſtemper has raged again. Another remark has been made, that theſe beetles always chuſe to depoſit their eggs not at a great diſtance from rivers, or large pieces of water, and in ſuch places the cattle have been moſt attacked. There might be many other circumſtances mentioned in favour of this opinion, as alſo the ſeveral experiments which have been made by ſome of the members of the Academy of Sciences at Paris, which are ſufficient to prove, that the diſtemper was not infectious, nor can be communicated by the cattle, notwithſtanding it has been treated as ſuch in many countries, where has been an immenſe loſs to the public of ſuch numbers of cattle and their hides; but this may require a particular treatiſe, therefore I ſhall not enlarge farther on this head at preſent.

The froſt ſtill continued very hard till toward the end of January, but not ſo violent as at the beginning; for had the wind continued to blow with ſo much force as it had done the three firſt days of the froſt, for any conſiderable time longer, there would have been few vegetables able to have reſiſted the cold, nor would the animal kingdom have fared much better; for the cold was ſo intenſe during thoſe few days, as to kill ſeveral of the weaker ſort of cattle, where they were much expoſed to the wind.

The Walnut-trees, Aſh, and ſeveral other trees, had moſt of their ſhoots of the former year deſtroyed, which cauſed them to be very late before they put out their new ſhoots the following ſpring, and theſe ſhoots were produced from the two and three years branches. The Fig-trees in many places were killed almoſt to the ground, eſpecially thoſe which were growing againſt the beſt aſpected walls, for thoſe on the north and north-weſt aſpects, as alſo the old ſtandard Fig-trees eſcaped better; but all thoſe ſtools and layers of theſe trees, which were growing in the nurſery-gardens, were ſo much injured by the froſt, as not to be recovered under three years, during which time there were ſcarce any of theſe plants to be ſold. The layers of Vines, as alſo of the Oriental Plane-tree, in the nurſeries, were likewiſe killed to the ground, and the old ſtools ſo much injured, that they had better have been dug up and thrown away, than to have continued them; for in ten years after they did not recover their former vigour, making their ſhoots ſo late in the ſummer, that their wood had not time to harden, and the firſt froſt in autumn frequently killed them half way to the ground.

Many other deciduous trees were equal ſufferers by this ſevere froſt, and the Evergreens were more generally injured, and abundance of them killed. The Pine and Pinaſter were ſo much hurt, as to loſe all their verdure, and in ſome places the young plants of the former ſort were entirely killed. The Roſemary, Lavender, Stœchas, Sage, and many other aromatic plants, were in many places quite deſtroyed, ſo that it was two or three years before the markets could be ſupplied with theſe; and in general the eſculent plants in the kitchen-gardens were killed, ſo that for ſome months the markets were not ſupplied with any quantity of garden ſtuff. The flower-gardens alſo were great ſufferers by this winter; for as the ſeaſons for ſome years before had been very temperate, few perſons had made any proviſion for a hard winter; and the cold ſetting in ſo very intenſe at the beginning, the miſchief was done before people could be provided with covering.

The Wheat in many parts of England, but eſpecially in the open common fields, was very much hurt, particularly on the top of the ridges, where, in ſeveral places there were broad naked ſpaces on the middle of the ridges, which in the ſpring appeared like ſo many foot-paths. And as the ſpring following was very dry, and the wind continuing to blow from the north and eaſt; theſe piercing winds entered the ground, which had been looſened by the froſt, and dried up the tender roots of the Corn, to the great prejudice of it; but ſome of the more expert farmers, who rolled their Wheat after the froſt was over, were well repaid by the great crops which their land produced them.

Were I to enter into all the particulars of the damages ſuſtained by this ſevere froſt in the gardens and fields, it would ſwell this work beyond the limits intended; ſo I hope, on the other hand, I ſhall not be condemned for having inſerted thus much, ſince, by the mention of theſe things, perſons may be inſtructed how to ſave many of their valuable plants in future winters, as alſo what ſorts are more liable to danger from froſts than others.

FRUCTIFEROUS [fructifer, *Lat.*] fruit-bearing, fruitful.

FRUCTUS. See Fruit.

FRUIT is the production of a tree or plant, for the propagation or multiplication of its kind; in which ſenſe fruit includes all kinds of ſeeds, with their furniture, &c. botaniſts uſe it to ſignify properly, that part of a plant wherein the ſeed is contained, which the Latins call Fructus, and the Greeks Καρπός.

The fruit of ſome plants are produced ſingly, as are their flowers, and ſometimes they are produced in cluſters, as in moſt fruit-trees, which are alſo fleſhy, but in many plants they are dry.

The word fruit is alſo uſed to ſignify an aſſemblage of ſeeds in a plant; as in a Pea, Bean, Ranunculus, &c. and in its general ſignification, for all kinds of grain, whether naked, or incloſed in cover, capſula, or pod, whether bony, fleſhy, ſkinny, membranous, or the like.

Fruit is the product or reſult of the flower, or that for whoſe production, nutrition, &c. the flower is intended.

The ſtructure and parts of different fruits are different in ſome things, but in all the ſpecies the eſſential parts of the fruit appear to be only continuations or expanſions of thoſe which are ſeen in the other parts of the tree.

Dr. Beale ſuggeſts ſome very good reaſons for a direct communication between the remoteſt parts of the tree and the fruit; ſo that the ſame fibres which conſtitute the root, trunk, and boughs, are extended into the very fruit.

Thus, if you cut open an Apple tranſverſly, you will find it to conſiſt chiefly of four parts, viz. 1ſt, a ſkin, or cortex, which is only a production of the ſkin or outer bark of the tree. 2dly, A parenchyma or pulp, which is an expanſion and intumeſcence of the inner bark of the tree. 3dly, The fibres, or ramifications of the woody part of the tree. 4thly, The core, which is the produce of the pith, or medulla of the plant, indurated or ſtrengthened by twigs of the wood and fibres inoſculated therewith. This ſerves to furniſh a cell, or lodge, for the kernels, filtrates the juice of the parenchyma, and conveys it thus prepared to the kernel.

Of the fibres, authors generally reckon fifteen branches, of which ten penetrate the parenchyma, and incline to the baſis of the flower; the other five aſcend more particularly from the pedicle or ſtalk, and meet with the former at the baſe of the flower, to which branches the capſulæ, or coats of the kernels are faſtened.

Theſe branches being firſt extended through the parenchyma to the flower, furniſh the neceſſary matter for the vegetation of it; but as the fruit increaſes, it intercepts the aliment, and thus the flower is ſtarved, and falls off.

In a Pear there are five parts to be diſtinguiſhed, viz. the ſkin, parenchyma, ramification, kernel, and acetarium.

The three firſt parts are common to the Apple. The kernel, obſerved chiefly in Choke Pears, or Breaking Pears, is a congeries of ſtrong corpuſcles, that are diſperſed throughout the whole parenchyma, but in the greateſt plenty, and cloſeſt together about the center, or acetarium; it is formed of the ſtony or calculous part of the nutritious juice.

The acetarium is a ſubſtance of a tart acid taſte, of a globular figure, incloſed in an aſſemblage of ſeveral of the ſtony parts before-mentioned.

In a Plumb, Cherry, &c. there are four parts, viz. a coat, parenchyma, ramification, and nucleus, or ſtone. The ſtone conſiſts of two very different parts; the external or harder part, called the ſtone, or ſhell, is a concretion of the ſtony, or calculous parts of the nutritious juice, like the kernel in Pears, within it. The inner, called the kernel, is ſoft, tender, and light, being derived from the pith, or medulla of the tree by ſeminal branches, which penetrate the baſe of the kernel.

The nut, or acorn, conſiſts of a ſhell, cortex, and medulla; the ſhell conſiſts of a coat and parenchyma, derived from the bark and wood of a tree.

The cortex conſiſts of an inner and outer part, the firſt is a duplicature of the inner tunic of the ſhell; the ſecond is a moſſy ſubſtance, derived from the ſame ſource as the parenchyma of the ſhell. But authors are not agreed, whether the medulla, or pulp of the kernel does ariſe from the pith of the tree, or the cortical part thereof.

Berries, as the Grape, &c. contain (beſides three general parts, viz. coat, parenchyma, and ramification) grains of a ſtony nature, to do the offices of ſeeds.

Fruits in general are ſerviceable in guarding, preſerving, and feeding the incloſed ſeed, in filtrating the coarſer more earthy, and ſtrong parts of the nutritious juice of the plant, and retaining it to themſelves, ſending none but the moſt pure, elaborated, and ſpirituous parts to the ſeed, for the ſupport and growth of the tender delicate embryo or plantule, which is therein contained.

FRUMENTACEOUS [Frumentaceous, *Lat.*] a term applied by botaniſts to all ſuch plants as have a conformity with Wheat (called in *Latin* Frumentum,) in reſpect either of their fruits, leaves, ears, or the like.

FRUMENTUM INDICUM. See Zea.

FRUTEX, a ſhrub; a vegetable of a genus between a tree and an herb, but of a woody ſubſtance. It is pretty difficult to determine wherein moſt of the writers on gardening and agriculture have made the diſtinction between trees and ſhrubs, or where to fix the difference or boundary, between the trees and ſhrubs, to ſay where one ends, and the other begins, for that cannot be determined by their growth; therefore the beſt definition which can be made of a ſhrub, to diſtinguiſh it from a tree, is its ſending forth many ſtems from the roots, whereas the trees have a ſingle trunk or body.

FRUTEX PAVONIUS. See Poinciana.

FRUTICOSE [Fruticoſus, *Lat.* ſhrubby,] are thoſe plants which are of a hard woody ſubſtance, and do not riſe to the height of trees.

FUCHSIA. Plum. Nov. Gen. 14. Lin. Gen. Plant. 1097. This plant was ſo named by Father Plumier, who diſcovered it in America, in honour of the memory of Leonard Fuchſius, a learned botaniſt.

The CHARACTERS are,

The flower hath no empalement; it hath one petal, with a cloſed tube, which is ſlightly cut into eight parts at the brim, ending in acute points; it hath four ſtamina the length of the tube, which are terminated by obtuſe ſummits. The oval germen is ſituated under the flower, ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes a ſucculent berry with four furrows, having four cells, containing ſeveral ſmall oval ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, the flower having four ſtamina and one ſtyle.

We know but one SPECIES of this genus at preſent, viz.

FUCHSIA (*Triphylla.*) Lin. Sp. Plant. 1191. *Three-leaved Fuchſia.* Fuchſia triphylla, flore coccineo. Plum. Nov. Gen. *Three-leaved Fuchſia with a ſcarlet flower.*

This plant is a native in the warmeſt parts of America; it was diſcovered by Father Plumier, in ſome of the French Iſlands in America, and was ſince found by the late Dr. William Houſtoun, at Carthagena in New Spain, from whence he ſent the ſeeds into England.

This is propagated by ſeeds, which muſt be ſown in pots filled with rich light earth, and plunged into a hot-bed of tanners bark, and treated in the ſame way as other ſeeds from warm countries. In about a month or ſix weeks after the ſeeds are ſown, the plants will begin to appear, when they ſhould be carefully cleared from weeds, and frequently refreſhed with water to promote their growth; and when they are about two inches high, they ſhould be ſhaken out of the pot, and ſeparated carefully; then plant each into a ſmall pot filled with light rich earth, and plunge them again into a hot-bed of tanners bark, being careful to ſcreen them from the ſun until they have taken new root; after which time they muſt have freſh air admitted to them every day in proportion to the warmth of the ſeaſon, and ſhould be frequently watered. As the ſeaſon advances and becomes warm, the glaſſes of the hot-bed ſhould be raiſed higher, to admit a greater ſhare of air to the plants, to prevent their drawing up weak; and when the plants are grown ſo tall as to reach the glaſſes, they ſhould be removed into the bark-ſtove, and plunged into the tan-bed. In winter theſe plants require to be kept very warm, and at that ſeaſon they muſt not have much water, but in ſummer it muſt be often repeated.

Theſe plants are too tender to thrive in the open air in this country, even in the hotteſt part of the year; therefore they ſhould conſtantly remain in the ſtove, obſerving to let in a large ſhare of freſh air in ſummer, but in winter they muſt be kept warm; with this management the plants will produce their flowers, and make a beautiful appearance in the ſtove, amongſt other tender exotic plants.

FUMARIA. Lin. Gen. Plant. 760. Tourn. Inſt. R. H. 421. tab. 237. Fumatory; in French, *Fumeterre.*

The CHARACTERS are,

The empalement of the flower is compoſed of two equal leaves placed oppoſite. The flower is of the ringent kind, approaching near to the butterfly flowers. The upper lip is plain, obtuſe, indented at the top, and reflexed; the nectarium at the baſe of this is obtuſe, and a little prominent. The under lip is like the upper in all its parts, but the baſe is keel-ſhaped; the nectarium at the baſe is leſs prominent. The chaps of the flower is four-cornered, obtuſe, and perfectly bifid; there are ſix equal broad ſtamina in each flower, divided in two bodies, included in the two lips, each being terminated by three ſummits. In the center is ſituated an oblong germen, ſupporting a ſhort ſtyle, crowned by an orbicular compreſſed ſtigma. The germen afterward becomes a ſhort pod with one cell, including roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Hexandria, which includes the plants whoſe flowers have their ſtamina in two bodies, and have ſix ſtamina. To this genus Dr. Linnæus has joined the Capnoides of Tournefort, the Cyſticapnos of Boerhaave, the Corydalis of Dillenius, and the Cucularia of Juſſieu, making them only ſpecies of the ſame genus.

The SPECIES are,

1. FUMARIA (*Officinalis*) pericarpis monoſpermis racemoſis, caule diffuſo. Lin. Sp. Plant. 700. *Fumatory with ſeed-veſſels growing in a racemus, with a ſingle ſeed and a diffuſed ſtalk.* Fumaria officinarum & Dioſcoridis, flore purpureo. C. B. 143. *The common Fumatory with a purple flower.*
2. FUMARIA (*Spicata*) pericarpiis monoſpermiis ſpicatis, caule erecto, foliolis filiformibus. Sauv. Monſp. 263. *Fumatory with ſeed-veſſels growing in a ſpike, with one ſeed, an upright ſtalk, and thread-like leaves.* Fumaria minor tenuifolia. C. B. 143. *Leſſer narrow-leaved Fumatory.*
3. FUMARIA (*Alba*) ſiliquis linearibus tetragonis, caulibus diffuſis acutangulis. Lin. Sp. Plant. 700. *Fumatory with narrow four-cornered pods, and diffuſed ſtalks, having acute angles.* Fumaria ſempervirens & floreas, flore albo. Flor. Bat. *Evergreen Fumatory with a white flower.*
4. FUMARIA (*Capnoides*) ſiliquis teretibus, caulibus diffuſis, angulis obtuſis. *Fumatory with taper pods and diffuſed ſtalks, having obtuſe angles.* Fumaria lutea. C. B. 143. *Yellow Fumatory.*
5. FUMARIA (*Claviculata*) ſiliquis linearibus, foliis cirrhiferis. Lin. Sp. Plant. 701. *Fumatory with narrow pods, and leaves having claſpers.* Fumaria claviculis donata. C. B. P. 143. *Fumatory with tendrils.*
6. FUMARIA (*Capreolata*) pericarpiis monoſpermis racemoſis, foliis ſcandentibus ſubcirrhoſis. Lin. Sp. Plant. 701. *Fumatory with ſeed-veſſels growing in a racemus, with one ſeed, and climbing leaves having ſhort tendrils.* Fumaria major ſcandens, flore pallidiore. Raii Hiſt. 405. *Greater climbing Fumatory with a paler flower.*
7. FUMARIA (*Cava*) caule ſimplici, bracteis longitudine florum. Lin. Sp. Plant. 699. *Fumatory with a ſingle ſtalk, and bracteæ as long as the flowers.* Fumaria bulboſa, radice cavâ, major. C. B. P. 143. *Greater bulbous Fumatory with a hollow root.*
8. FUMARIA (*Bulboſa*) caule ſimplici, bracteis brevioribus multifidis, radice ſolida. *Fumatory with a ſingle ſtalk, ſhorter many pointed bracteæ, and a ſolid root.* Fumaria bulboſa, radice non cavâ, major. C. B. P. 144. *Greater bulbous Fumatory with a ſolid root.*
9. FUMARIA (*Cucularia*) ſcapo nudo. Hort. Cliff. 351. *Fumatory with a naked ſtalk.* Capnorchis Americana. Boerh. Ind. alt. 1. 309. and the Fumaria tuberoſa inſipida. Cornut. 129. *Tuberous inſipid Fumatory.*
10. FUMARIA (*Veſicaria*) ſiliquis globoſis inflatis. Hort. Upſal. 207. *Fumatory with globular inflated pods.* Cyſticapnos Africana ſcandens. Boerh. Ind. alt. 1. 310. *Climbing African Cyſticapnos.*
11. FUMARIA (*Eneaphylla*) foliis triternatis, foliolis cordatis. Lin. Sp. Plant. 700. *Fumatory with leaves compoſed of three trifoliate ſmall leaves, which are heart-ſhaped.* Fumaria enneaphyllos Hiſpanica ſaxatilis. Bocc. Muſ. 2. p. 83. *Five-leaved Rock Fumatory of Spain.*
12. FUMARIA (*Sempervirens*) ſiliquis linearibus paniculatis, caule erecto. Hort. Upſal. 207. *Fumatory with narrow pods growing in panicles, and an upright ſtalk.* Capnoides. Tourn. Inſt. R. H. 423. *Baſtard Fumatory.*

The firſt ſort is the common Fumatory which is uſed in medicine. This grows naturally on arable land in moſt parts of England; it is a low annual plant, and flowers in April, May, and June; and very often from plants which riſe late in the ſummer, there will be a ſecond crop in autumn. The juice of this plant is greatly commended for bilious cholics. It is never cultivated in gardens.

The ſecond ſort grows naturally in the ſouth of France, Spain, and Portugal, but is preſerved in botanic gardens for the ſake of variety. It is an annual plant, which riſes from the ſcattered ſeeds better than when it is ſown with care; the ſtalks of this grow more erect, the leaves are very finely divided, and the flowers grow in a cloſe ſpike; they are of a deep red colour, and flower about the ſame time as the common ſort.

The third ſort grows naturally on the borders of the Mediterranean Sea; it was firſt brought to England from Tangier. This is a perennial plant, which ſends out from the root many branching ſtalks, which riſe about ſix or eight inches high, growing in tufts or bunches; the leaves are very much divided, the ſtalks are angular, and the flowers grow in looſe panicles upon naked foot-ſtalks, which come out from the diviſions of the branches; they are of a whitiſh yellow colour, and there is a ſucceſſion of them moſt part of the year.

The fourth ſort hath an appearance very like the third, and by ſome it is ſuppoſed to be only a variety of that, but is undoubtedly a diſtinct ſpecies; for I have cultivated both more than forty years, and never yet found either of them to vary. The ſtalks of this ſort have blunt angles, whereas thoſe of the third are acute; they are of a purpliſh colour, and the flowers grow in looſer panicles, each having a longer foot-ſtalk than thoſe of the other; they are of a bright yellow colour, and there is a ſucceſſion of them great part of the year.

Theſe two ſorts continue green all the year, and except in very ſevere froſt, are always in flower, which make a pretty appearance; they grow beſt on walls or rocks, and are very proper for the joints of grottos, or any rock-work; where, if a few plants are planted, or the ſeeds ſcattered, they will multiply faſt enough from their ſcattering ſeeds, which are caſt out of the pods by the elaſtic ſpring of the valves when ripe, to a conſiderable diſtance; and as the plants will require no care to cultivate them, they ſhould not be wanting in gardens.

The fifth ſort grows in ſtony and ſandy places in ſome parts of England; it is an annual plant with trailing ſtalks, ſending out claſpers from the leaves, which faſten to any of the neighbouring plants. It flowers in May and June, but is never cultivated in gardens.

The ſixth ſort is an annual plant with many trailing ſtalks, which grow about a foot long, ſending out a few ſhort tendrils, whereby they faſten to any neighbouring ſupport; the flowers come out from the ſide of the ſtalks in looſe bunches; they are of a whitiſh herbaceous colour, with a purple ſpot on the upper lip. This flowers in May and June. It grows in France and Italy, on ſtony places in the ſhade.

The ſeventh ſort grows naturally in the ſouth of France and Italy, and was ſome years paſt preſerved in the Engliſh gardens by way of ornament, but is now rarely to be found here; it was titled Radix cava, or hollow root, from its having a pretty large tuberous root hollowed in the middle. The ſtalk of this ſort riſes about ſix inches high, and does not divide, but is garniſhed toward the bottom with one ramous leaf, ſomewhat like the common Fumatory, but the lobes are broader; the flowers grow in a ſpike at the top of the ſtalk; they are of a pale herbaceous colour, and appear in April. This plant delights in the ſhade, and is multiplied by offſets, for it rarely ripens ſeeds in England.

The eighth ſort is pretty common in many of the old gardens in England; it grows naturally in the ſouth of France, in Germany and Italy. This hath a pretty large round ſolid root of a yellowiſh colour, from which come out branching leaves like thoſe of the laſt ſort, but the lobes are longer; the flowers grow in ſpikes on the top of the ſtalks; they are of a purple colour, and come out early in April. The ſtalks of this ſort are ſingle, and riſe about four or five inches high.

There is a variety of this with green flowers, which is mentioned in moſt of the books; but all the plants of this ſort which I have yet ſeen, are only abortive, having no real flower, only a green bractea, which has been generally taken for the flowers: there is alſo mentioned a larger ſort; but if there is one which is really different from the common ſort, I have not ſeen it in the Engliſh gardens, nor the yellow and white flowering ſorts, which are alſo mentioned in many of the books.

The ninth ſort grows naturally in North America; this hath a ſcaly root about the ſize of a large Hazel Nut, from which come out three or four leaves upon ſlender foot-ſtalks; theſe are divided into three parts, each of theſe parts is compoſed of many ſmaller diviſions, which have narrow lobes, divided into three parts almoſt to the bottom; the flower-ſtalk is naked, and eight or nine inches long; this is terminated by four or five flowers, growing in a looſe ſpike; theſe have two petals, which are reflexed backward, and form a ſort of fork toward the foot-ſtalk, and at their baſe are two horned nectariums, which ſtand horizantal. The flowers are of a dirty white colour and appear in May, but rarely produce ſeeds here.

This is propagated by offſets from the root; it loves a ſhady ſituation and a light ſoil; the beſt time to tranſplant the roots is in autumn, when the leaves are decayed, for it ſhoots pretty early in the ſpring, therefore it would not be ſafe to remove them at that ſeaſon.

The tenth ſort grows naturally at the Cape of Good Hope; this is an annual plant, with trailing ſtalks which are two or three feet long, dividing into many ſmaller, which are garniſhed with ſmall branching leaves ſhaped like thoſe of the common Fumatory, but end with tendrils, which claſp to any neighbouring plants, and thereby the ſtalks are ſupported; the flowers are produced in looſe panicles, which proceed from the ſide of the ſtalks; they are of a whitiſh yellow colour, and are ſucceeded by globular ſwollen pods, in which are contained a row of ſmall ſhining ſeeds.

This is propagated by ſeeds, which ſhould be ſown upon a moderate hot-bed in the ſpring; and when the plants are fit to remove, they muſt be each planted in a ſmall pot filled with light earth, and plunged again into the hot-bed, where they muſt be ſhaded from the ſun till they have taken new root; after which they ſhould have a large ſhare of air admitted to them at all times in mild weather, to prevent their drawing up weak; and as ſoon as the ſeaſon is favourable, they ſhould be inured to bear the open air, to which they may be removed the beginning of June, when they may be ſhaken out of the pots, preſerving all the earth to their roots, and planted in a warm border, where their ſtalks ſhould be ſupported with ſticks to prevent their trailing on the ground; and in July the plants will flower, and continue a ſucceſſion of flowers till the froſt deſtroys the plants; the ſeeds ripen in autumn.

The eleventh ſort grows naturally upon old walls, or rocky places in Spain and Italy; this hath weak trailing ſtalks which are much divided, and are garniſhed with ſmall leaves divided into three parts, each of which hath three heart-ſhaped lobes; the flowers are produced in ſmall looſe panicles from the ſide of the ſtalks, they are of a greeniſh white, and appear moſt of the ſummer months. It is an abiding plant, which propagates itſelf by the ſeeds that ſcatter, and thrives beſt in a ſhady ſituation, and on old walls or buildings.

The twelfth ſort is an annual plant with an upright ſtalk, which grows a foot and a half high, round and very ſmooth, ſending out ſeveral branches upward; theſe are garniſhed with ſmooth branching leaves, of a pale colour, which are divided like the common ſort, but the ſmall leaves are larger and more obtuſe; the flowers are produced in looſe panicles from the ſides of the ſtalks, and at the extremity of the branches; they are of a pale purple colour, with yellow chaps (or lips); theſe are ſucceeded by taper narrow pods an inch and a half long, which contain many ſmall ſhining black ſeeds. This flowers during moſt of the ſummer months, and the ſeeds ripen in July, Auguſt,

guſt, and September. If the ſeeds of this plant are permitted to ſcatter, the plants will come up without any trouble, and require no other care but to thin them where they are too cloſe, and keep them clean from weeds.

Theſe plants may be ſuffered to grow on walls, and in ſome abject part of the garden; for if they are admitted into the borders of the pleaſure-garden, they will ſcatter their ſeeds, and become troubleſome weeds; but they are very proper plants to grow on ruins, or on the ſides of grottos or rock-work, where, by their long continuance in flower, they will have a good effect.

The fifth, ſixth, ſeventh, and eighth ſorts are propagated by offsets, as other bulbous-rooted flowers; theſe produce their flowers in the beginning of April, and are very pretty ornaments to borders in a ſmall flower-garden. They are extreme hardy, but do not increaſe very faſt, ſeldom producing ſeeds with us; and their bulbs do not multiply very much, eſpecially if they are often tranſplanted. They love a light ſandy ſoil, and ſhould be ſuffered to remain three years undiſturbed, in which time they will produce ſeveral offsets. The beſt ſeaſon for tranſplanting them is from May to Auguſt, when the leaves begin to die off; for if they are taken up when their leaves are freſh, it will greatly weaken their roots.

FURZ. See GENISTA.

G.

GALANTHUS. Lin. Gen. Plant. 362. Narciſſo-leucoium. Tourn. Inſt. R. H. 387. tab. 208. The Snow-drop; in French, *Perce-neige*.

The CHARACTERS are,

The ſpatha or ſheath of the flower is oblong, blunt, and compreſſed. This opens ſideways, and becomes a dry ſkin; the flower has three oblong concave petals, which ſpread open, and are equal; in the bottom is ſituated the three-leaved nectarium, which is cylindrical, obtuſe, and indented at the top; under the flower is ſituated the oval germen, ſupporting a ſlender ſtyle, which is longer than the ſtamina, crowned by ſingle ſtigma; this is attended by ſix ſhort hairy ſtamina, terminated by oblong pointed ſummits, which are gathered together. The germen afterward becomes an oval capſule which is obtuſe and three-cornered, opening in three cells, which are filled with roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, which includes the plants whoſe flowers have ſix ſtamina and one ſtyle.

This plant, as alſo the great Snow-drop, was by Dr. Tournefort ranged together under the title of Narciſſo-leucoium; which being a compound name, Dr. Linnæus has altered it to this of Galanthus; and has ſeparated the great Snow-drop from this, and given the ſimple name of Leucoium to that genus.

We know but one SPECIES of this genus, viz.

GALANTHUS (*Nivalis.*) Lin. Hort. Cliff. 134. The common Snow-drop. *Leucoium bulboſum trifolium minus.* C. B. P. The leaſt bulbous Snow-drop with three leaves.

There is a variety of this with double flowers.

Theſe flowers are valued for their early appearance in the ſpring, for they uſually flower in February when the ground is often covered with ſnow. The ſingle ſort comes out the firſt, and though the flowers are but ſmall, yet when they are in bunches, they make a very pretty appearance; therefore theſe roots ſhould not be planted ſingle, as is ſometimes practiſed by way of edging to borders; for when they are ſo diſpoſed, they make very little appearance. But when there are twenty or more roots growing in a cloſe bunch, the flowers have a very good effect; and as theſe flowers thrive well under trees or hedges, they are very proper to plant on the ſides of the wood-walks, and in wilderneſs-quarters; where, if they are ſuffered to remain undiſturbed, the roots will multiply exceedingly. The roots may be taken up the latter end of June, when their leaves decay, and may be kept out of the ground till the end of Auguſt, but they muſt not be removed oftener than every third year.

GALE. See MYRICA.

GALEGA. Lin. Gen. Plant. 770. Tourn. Inſt. R. H. 398. tab. 222. Goat's-rue.

The CHARACTERS are,

The empalement of the flower is ſhort, tubulous, and of one leaf, indented in five parts. The flower is of the butterfly kind; the ſtandard is oval, large, and reflexed; the wings are near the length of the ſtandard; the keel is erect, oblong, and compreſſed; the under ſide toward the point is rounded, but the upper is acute; there are ten ſtamina, which join above their middle, and are terminated by ſmall ſummits. In the center is ſituated a narrow, cylindrical, oblong germen, ſupporting a ſlender ſtyle, crowned by a ſtigma terminated by a puncture. The germen afterward becomes a long pointed pod, incloſing ſeveral oblong kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, which includes thoſe plants whoſe flowers have ten ſtamina joined in two bodies.

The SPECIES are,

1. GALEGA (*Officinalis*) leguminibus ſtrictis erectis, foliolis lanceolatis ſtrictis nudis. Lin. Sp. Plant. 1062. *Goat's-rue with erect cloſe pods, and ſpear-ſhaped naked leaves.* Galega vulgaris, floribus cæruleis. C. B. P. 352. *Common Goat's-rue with blue flowers.*
2. GALEGA (*Africana*) foliolis lanceolatis obtuſis, floribus ſpicatis longioribus, ſiliquis craſſioribus. *Goat's-rue with obtuſe ſpear-ſhaped leaves, flowers growing in longer ſpikes, and thicker pods.* Galega Africana, floribus majoribus ſiliquis craſſioribus. Tourn. Inſt. R. H. 399. *African Goat's-rue, with larger flowers and thicker pods.*
3. GALEGA (*Fruteſcens*) foliis ovatis, floribus paniculatis alaribus, caule fruticoſo. *Goat's-rue with oval leaves, and flowers growing in panicles from the ſides of the ſtalks, which are ſhrubby.* Galega Americana, foliis ſubrotundis, floribus coccineis. Houſt. MSS. *American Goat's-rue with roundiſh leaves and ſcarlet flowers.*
4. GALEGA (*Virginiana*) leguminibus retrofalcatis compreſſis villoſis ſpicatis, calycibus lanatis, foliolis ovali-oblongis acuminatis. Amœn. Acad. 3. p. 18. *Goat's-rue with hairy, compreſſed, ſickle-ſhaped pods, oblong oval-*

oval-pointed leaves, and woolly empalements. Orobus Virginianus, foliis fulva lanugine incanis, foliorum nervo in ſpinam aberunte. Pluk. Mant. 142.

5. GALEGA (*Purpurea*) leguminibus ſtrictis adſcendentibus glabris racemoſis terminalibus, ſtipulis ſubulatis, foliis oblongis glabris. Flor. Zeyl. 301. *Goats-rue with cloſe, ſmooth, aſcending pods, terminating the ſtalks in an oblong bunch, awl-ſhaped ſtipulæ, and oblong ſmooth leaves.* Coronilla Zelanica herbacea, flore purpuraſcente. Burm. Zeyl. 77.

The firſt ſort grows naturally in Italy and Spain, but is propagated in the Engliſh gardens for medicinal uſe. This hath a perennial root, compoſed of many ſtrong fibres, which are frequently jointed, from which ariſe many channelled hollow ſtalks, from two to three feet high, which are garniſhed with winged leaves, compoſed of ſix or ſeven pair of narrow ſpear-ſhaped lobes, terminated by an odd one, which are ſmooth and entire; the flowers terminate the ſtalks growing in ſpikes, they are of the Pea-bloſſom ſhape, and of a pale blue colour, and are diſpoſed in looſe ſpikes. They appear in June, and are ſucceeded by taper pods about one inch and a half in length, having one row of kidney-ſhaped ſeeds, which ripen toward the end of Auguſt.

There is a variety of this with white flowers, and another with variegated flowers, which have accidentally been produced from ſeeds, ſo are not conſtant, therefore are only mentioned here.

The ſecond ſort grows naturally in Africa; this differs from the former, in having larger leaves, which are compoſed of eight or ten pair of lobes, broader and blunter at their ends than thoſe of the common ſort; the flowers are larger, and the ſpikes are longer; the ſeed-pods are alſo much thicker than thoſe of the common ſort, but in other reſpects are very like it.

Theſe plants are propagated by ſeeds, which may be ſown either in the ſpring or autumn, upon a bed of ground in an open ſituation; and when the plants come up, they muſt be kept clean from weeds till they are ſtrong enough to remove; then a ſpot of ground ſhould be prepared, in ſize proportionable to the quantity of plants deſigned; this ſhould be well dug, and cleared from the roots of all noxious weeds; then the plants ſhould be carefully taken up, and planted in rows at a foot and a half diſtance, and in the rows one foot aſunder, obſerving to water them till they have taken new root; after which they will require no farther care to keep them clean from weeds, which may be eaſily done by hoeing of the ground frequently between the plants, and in the ſpring the ground between the rows ſhould be dug, which will encourage their roots, and cauſe them to ſhoot out vigorous ſtalks; and if their ſtalks are cut down before the ſeeds are formed every year, the roots will continue the longer, eſpecially if they grow on a light dry ſoil. The ſeeds of theſe will grow whereever they are permitted to ſcatter, ſo that plenty of the plants will come up without any care, and theſe may be tranſplanted and managed in the ſame manner as is before directed.

The firſt ſort is uſed in medicine; it is accounted cordial, ſudorific, and alexipharmic, ſo very good againſt peſtilential diſtempers, expelling the venom through the pores of the ſkin, and is of uſe in all kinds of fevers. Mr. Boyle, in his treatiſe of the Wholſomeneſs and Unwholſomeneſs of the Air, beſtows three or four pages, in celebrating the virtues of Goats-rue in peſtilential and malignant diſeaſes, from his own obſervation and experience.

The third ſort was diſcovered by the late curious botaniſt Dr. William Houſtoun, at Campeachy, from whence he ſent the ſeeds into Europe. This plant is propagated by ſeeds, which muſt be ſown on a hot-bed early in the ſpring; and when the plants come up, and are fit to tranſplant, they muſt be tranſplanted each into a ſeparate ſmall pot, and plunged into a hot-bed of tanners bark, ſhading them from the ſun till they have taken new root; then they muſt be treated as hath been directed for other tender plants, which are kept in the bark-ſtove. With this management they will flower in July, and in September they will perfect their ſeeds, but the plants may be preſerved through the winter in the bark-ſtove.

The fourth ſort grows naturaly in Virginia and Carolina; this hath a perennial root, and an annual ſtalk which riſes three feet high; the lobes of the leaves are oblong and oval, generally ſeven or nine to each leaf: the whole plant is covered with a ſilvery down. The flowers are of a red colour, and are produced in ſpikes at the end of the branches: theſe are ſucceeded by ſickle-ſhaped compreſſed pods of a ſilvery colour, containing one row of kidney-ſhaped ſeeds.

This plant, although it is tolerable hardy, yet it is with difficulty preſerved in gardens; for the ſeeds rarely ripen in England, and the plants are often deſtroyed by froſt in winter. The only method in which I have been able to keep the plant, has been by potting them, and placing them in a common frame in winter, where they enjoyed the free air in mild weather, but were protected from froſt; in this way I have kept the plant three years, but it has not ripened ſeeds here.

The fifth ſort grows naturally in Ceylon, and in many parts of India, from whence I have received the ſeeds. This ſort was annual here, and decayed before the ſeeds were ripe. It hath an herbaceous ſtalk, which riſes two feet high, garniſhed with winged leaves, compoſed of eight or nine pair of oval lobes, terminated by an odd one; the foot-ſtalks of the flowers come out oppoſite to the leaves; theſe ſuſtain a long looſe ſpike or thyrſe of ſmall purple flowers, which are ſucceeded by ſlender erect pods.

This may be cultivated in the ſame way as the third ſort; and if the plants are brought forward early in the ſpring, if the ſummer proves warm, the ſeeds may ripen.

GALENIA. Lin. Gen. Plant. 443. Sherardia. Ponted. Epiſt. 14.

The title of this genus was given to it by Dr. Linnæus, from the famous phyſician Galen.

The CHARACTERS are,

The flower hath a ſmall quadrifid empalement of one leaf; it hath no petals, but hath eight hairy ſtamina the length of the empalement, terminated by double ſummits. In the center is ſituated a roundiſh germen, ſupporting two reflexed ſtyles, crowned by ſimple ſtigmas. The empalement afterward becomes a roundiſh capſule with two cells, containing two oblong angular ſeeds.

This genus of plants is ranged in the ſecond ſection of Linnæus's eighth claſs, intitled Octandria Digynia, which includes thoſe plants whoſe flowers have eight ſtamina and two ſtyles.

We know but one SPECIES of this genus, viz.

GALENIA (*Africana.*) Hort. Cliff. 150. *Shrubby Galenia.* Sherardia. Ponted. Epiſt. 14. and the Atriplex Africana, lignoſa fruteſcens, roſmarini foliis. Hort. Piſ. 20. *Shrubby African woody Atriplex, with Roſemary leaves.*

This ſhrub grows naturally at the Cape of Good Hope, and in other parts of Africa; it riſes with a ſhrubby ſtalk about four or five feet high, ſending out many weak branches, garniſhed with very narrow leaves, which are placed irregularly on every ſide the branches; they are of a light green, with a furrow running longitudinally through the middle; the flowers are produced in looſe panicles from the ſide and at the end of the branches; they are very ſmall, and have no petals, ſo make little appearance. The flowers come out in July and Auguſt, but are not ſucceeded by ſeeds in England.

This plant will not live through the winter in the open air in England, ſo muſt be placed in the green-houſe, or under a frame, with other hardy exotic plants, where it may have a large ſhare of air in mild weather, for it only requires to be protected from froſt. In the ſummer it may be expoſed in the open air, with other plants of the ſame country, and in dry weather it muſt be frequently watered. This may be propagated by cuttings, which, if planted during any of the ſummer months, and watered frequently, will take root in about five or ſix weeks, and may then be treated as is directed for the old plants.

GALEOPSIS. Lin. Gen. Plant. 637. Tourn. Inſt. R. H. 185. tab. 86. Stinking Dead Nettle.

The Characters are,

The empalement of the flower is tubulous, of one leaf, cut into five ſegments, which end in acute points. The flower is of the lip kind, having a ſhort tube; the chaps are a little broader, but the length of the empalement; from the baſe to the under lip, it is on both ſides ſharply indented; the upper lip is concave, roundiſh, and ſawed at the top; the under lip is trifid, the middle ſegment being the largeſt, which is crenated. It hath four ſtamina incloſed in the upper lip, two being ſhorter than the other, terminated by roundiſh bifid ſummits. In the center is ſituated a quadrifid germen, ſupporting a ſlender ſtyle, crowned by a bifid acute ſtigma. The germen afterward become four naked ſeeds, ſitting in the rigid empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourteenth claſs, intitled Didynamia Gymnoſpermia, which includes thoſe plants whoſe flowers have two long and two ſhort ſtamina, and the ſeeds are naked.

The Species are,

1. Galeopsis (*Ladanum*) internodiis caulinis æqualibus, verticillis omnibus remotis. Lin. Sp. Plant. 579. *Stinking Hedge Nettle, with equal diſtances between the joints, and whorls growing at a diſtance.* Sideritis arvenſis anguſtifolia rubra. C. B. P. 233. *Red narrow-leaved Field Ironwort.*
2. Galeopsis (*Tetrahit*) internodiis ſuperne incraſſatis, verticillis ſummis ſubcontiguis. Lin. Sp. Plant. 579. *Stinking Hedge Nettle, whoſe joints are thicker above, and the whorls at the top growing near each other.* Lamium cannabino folio vulgare. Raii Syn. Ed. 3. p. 240. *Common Dead Nettle with a Hemp leaf.*
3. Galeopsis (*Specioſa*) corollâ flavâ, labio inferiore maculato. Flor Lapp. 193. *Stinking Hedge Nettle with a yellow flower, whoſe under lip is ſpotted.* Lamium cannabinum aculeatum flore luteo ſpecioſo, labiis purpureis. Pluk. Alm. 204. *Prickly Hemp Dead Nettle, with a beautiful yellow flower and purple lips.*
4. Galeopsis (*Galeobdolon*) verticillis ſexfloris, involucro tetraphyllo. Lin. Sp. Plant. 780. *Stinking Hedge Nettle with ſix flowers in each whorl, and a four-leaved involucrum.* Galeopſis ſive urtica iners flore luteo. J. B. 3. 323. *Stinking or Dead Nettle with a yellow flower.*
5. Galeopsis (*Orientale*) verticillis bifloris, foliis oblongo-cordatis. *Stinking Hedge Nettle with two flowers in each whorl, and oblong heart-ſhaped leaves.* Galeopſis Orientalis ocimaſtri folio, flore majore flaveſcente. H. R. Par. *Eaſtern ſtinking Hedge Nettle, with an Ocimaſtrum leaf, and a larger yellowiſh flower.*
6. Galeopsis (*Hiſpanica*) caule piloſo, calycibus labio corollæ ſuperiore longioribus. Lin. Sp. Plant. 580. *Stinking Hedge Nettle with a hairy ſtalk, and the empalement longer than the upper lip of the petal.* Galeopſis annua Hiſpanica, rotundiore folio. Inſt. R. H. 186. *Annual Spaniſh ſtinking Hedge Nettle, with a rounder leaf.*

Theſe are all of them annual plants, except the fourth ſort; the three firſt grow naturally in England. The firſt is found upon arable land in many places; the ſecond grows upon dunghills, and by the ſide of paths, in many parts of England. The third ſort grows chiefly in the northern counties, but I have found it growing wild in Eſſex, within ten miles of London. Theſe plants are ſeldom cultivated in gardens, for if their ſeeds are permitted to ſcatter, the plants will come up as weeds wherever they are allowed a place.

The fourth is a perennial plant with a creeping root; this grows in the woods and under hedges in moſt parts of England. The fifth grows in the Levant; this is a biennial plant, which periſhes ſoon after the ſeeds are ripe. It is preſerved in botanic gardens for the ſake of variety, but hath no great beauty.

GALEOPSIS FRUTESCENS. See Prasium.

GALIUM. Lin. Gen. Plant. 117. Tourn. Inſt. R. H. 114. tab. 39. Ladies Bedſtraw, or Cheeſe-rennet; in French, *Caillelait*.

The Characters are,

The flower hath a ſmall empalement indented in four parts, ſitting upon the germen. It hath one petal, divided into four ſegments almoſt to the bottom; and four awl-ſhaped ſtamina which are ſhorter than the petal, terminated by ſingle ſummits. It hath a twin germen ſituated under the flower, ſupporting a ſlender half bifid ſtyle, crowned by a globular ſtigma. The germen afterward become two dry berries, which are joined together, each incloſing a large kidney-ſhaped ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetrandria Monogynia, which includes thoſe plants whoſe flowers have four ſtamina and one ſtyle.

The Species are,

1. Galium (*Verum*) foliis octonis linearibus ſulcatis, ramis floriferis brevibus. Hort. Cliff. 34. *Ladies Bedſtraw with eight narrow furrowed leaves, and ſhort flowering branches.* Galium luteum. C. B. P. 335. *Yellow Ladies Bedſtraw.*
2. Galium (*Mollugo*) foliis octonis ovato-linearibus ſubſerratis patentiſſimis mucronatis, caule flaccido, ramis patentibus. Lin. Sp. Plant. 107. *Ladies Bedſtraw with eight oval narrow leaves, which are ſpread open, ſawed, and pointed, a weak ſtalk, and ſpreading branches.* Mollugo montana latifolia ramoſa. C. B. P. 333. *Branching broad-leaved Mountain Mollugo.*
3. Galium (*Purpureum*) foliis verticillatis lineari-ſetaceis, pedunculis folio longioribus. Hort. Cliff. 34. *Ladies Bedſtraw with narrow briſtly leaves growing in whorls, and foot-ſtalks of the flowers longer than the leaves.* Galium nigro-purpureum montanum tenuifolium. Col. Ecphr. 1. p. 298. C. B. P. 335. *Narrow-leaved Mountain Ladies Bedſtraw, with a black purple flower.*
4. Galium (*Glaucum*) foliis verticillatis linearibus pedunculis dichotomis, ſummo caule floriferis. Prod. Leyd. 256. *Ladies Bedſtraw with narrow leaves growing in whorls, foot-ſtalks divided by pairs, and flowers growing at the top of the ſtalk.* Galium ſaxatile glauco folio. Bocc. Muſ. 2. p. 172. *Rock Ladies Bedſtraw with a gray leaf.*
5. Galium (*Rubrum*) foliis verticillatis linearibus patulis, pedunculis breviſſimis. Hort. Cliff. 34. *Ladies Bedſtraw with narrow leaves growing in whorls, and ſhort foot-ſtalks.* Galium rubrum. C. B. P. 335. *Red Ladies Bedſtraw.*
6. Galium (*Boreale*) foliis quaternis lanceolatis trinerviis glabris, caule erecto, ſeminibus hiſpidis. Flor. Lappon. 60. *Ladies Bedſtraw with four ſmooth ſpear-ſhaped leaves having three veins, an upright ſtalk, and rough ſeeds.* Rubia pratenſis lævis acuto folio. C. B. P. 333. *Smooth Meadow Madder with an acute leaf.*
7. Galium (*Album*) foliis verticillatis, lineari-lanceolatis, ramis floriferis longioribus. *Ladies Bedſtraw with narrow ſpear-ſhaped leaves growing in whorls, and longer branches of flowers.* Galium album vulgare. Tourn. Inſt. R. H. 113. *Common white Ladies Bedſtraw.*
8. Galium (*Linifolium*) foliis lineari-lanceolatis glabris, caule erecto ramoſiſſimo. *Ladies Bedſtraw with ſeven narrow, ſmooth, ſpear-ſhaped leaves, and an upright branching ſtalk.* Galium album linifolium. Barrel. Obſer. 99. *White Ladies Bedſtraw with a Flax leaf.*
9. Galium (*Paluſtre*) foliis quaternis obovatis inæqualibus, caulibus diffuſis. Flor. Suec. 119. *Ladies Bedſtraw with four unequal oval leaves, and a diffuſed ſtalk.* Galium paluſtre album. C. B. P. 335. *White Marſh Ladies Bedſtraw.*

The firſt of theſe plants (which is the ſort commonly uſed in medicine) is very common in moiſt meadows, and in paſture grounds, in ſeveral parts of England. The other varieties are preſerved in curious botanic gardens, but as they are plants of very little beauty, and are ſubject to ſpread very far, and over-run whatever plants grow near them, they are ſeldom cultivated in other gardens.

Theſe ſorts may any of them be propagated by parting their roots, which ſpread and increaſe very faſt, either in the ſpring or autumn, and will grow almoſt in any ſoil or ſituation, eſpecially the firſt ſort; the other ſorts require a drier ſoil, but will all grow in any ſituation.

GALLERIES, are ornaments made with trees of various kinds, which are very common in all the French gardens, but are ſeldom introduced into the Engliſh gardens, eſpecially ſince the taſte for clipped trees has been exploded; but as there may be ſome who yet fancy theſe obſolete ornaments, I ſhall juſt mention the way of conſtructing them.

In order to make a gallery in a garden with porticoes and arches, a line muſt firſt be drawn of the length you deſign the gallery to be; which being done, it is to be planted with Hornbeam, as directed under the article Hornbeam; which Hornbeam thus planted, is to be the foundation of the gallery.

The management of them is not very difficult; they require only to be digged about, and ſheared a little when there is occaſion.

The chief curioſity required is in the ordering the fore-part of the gallery, and in forming the arches.

Each pillar of the porticoes or arches ought to be four feet diſtant one from the other; the gallery twelve feet high, and ten feet wide, that there may be room for two or three perſons to walk a-breaſt.

When the Hornbeams are grown to the height of three feet, the diſtance of the pillars well regulated, and the ground-work of the gallery finiſhed, the next thing to be done is to form the frontiſpiece: to perform which you muſt ſtop the Hornbeam between two pillars at the height, and run up a trellis made for that purpoſe, which forms the arch.

As it grows up you muſt with your ſhears even thoſe boughs that outſhoot the others; in time they will grow ſtrong, and may be kept in form by the ſhears.

Portico galleries may be covered with Lime-trees.

GARCINIA. Lin. Gen. Plant. 526. The Mangoſteen.

The Characters are,

The flower hath a one-leaved empalement, which is permanent. It hath four roundiſh concave petals, which ſpread open, and are larger than the empalement. It hath ſixteen ſtamina which are erect, and form a cylinder, terminated by roundiſh ſummits. In the center is ſituated an oval germen, with ſcarce any ſtyle, but is crowned by a buckler-ſhaped plain ſtigma divided into eight parts, and is permanent. The germen afterward becomes a thick globular berry with one cell, including eight hairy fleſhy ſeeds, which are convex and angular.

This genus of plants is ranged in the firſt ſection of Linnæus's eleventh claſs, intitled Dodecandria Monogynia, which includes thoſe plants whoſe flowers have twelve ſtamina and one ſtyle.

We have but one Species of this genus, viz.

Garcinia (*Mangoſtana.*) Hort. Cliff. 182. *The Mangoſtan, or Mangoſteen.* Arbor peregrina aurantio ſimili fructu. Cluſ. Exot. 12. *Foreign Tree with a fruit like the Orange.*

This tree grows naturally in the Molucca Iſlands, and alſo in the inland parts of New Spain, from whence I received perfect ſpecimens, which were ſent me by Mr. Robert Millar, who gathered them near Tolu, but did not know the tree. It riſes with an upright ſtem near twenty feet high, ſending out many branches on every ſide, which are placed oppoſite, and ſtand oblique to each other, and not at right angles; the bark of the branches is ſmooth, of a gray colour, but on the tender ſhoots it is green, and that of the trunk is of a darker colour and full of cracks: the leaves are of the ſpear-ſhape, and entire; they are ſeven or eight inches long, and about half ſo much in breadth in the middle, gradually diminiſhing to both ends, of a lucid green on their upper ſide, and of an Olive colour on their under, having a prominent midrib through the middle, with ſeveral ſmall veins running from that to both ſides of the leaf. The flower is like that of a ſingle Roſe, compoſed of four roundiſh petals, which are thick at their baſe, but are thinner toward their ends; they are of a dark red colour. The fruit which ſucceeds the flower is round, the ſize of a middling Orange; the top is covered by a cap, which was the ſtigma on the top of the ſtyle, and remains to the top of the fruit, and is indented in rays to the number of ſix or ſeven, which are obtuſe. The ſhell of the fruit is like that of the Pomegranate, but ſofter, thicker, and fuller of juice; it is green at firſt, but changes to a dark brown with ſome yellowiſh ſpots; the inſide of the fruit is of a Roſe colour, and divided into ſeveral parts by thin partitions, as in Oranges, in which the ſeeds are lodged, ſurrounded by a ſoft juicy pulp of a delicious flavour, partaking of the Strawberry and the Grape, and is eſteemed one of the richeſt fruits in the world; the trees naturally growing in the form of Pyrabolas, whoſe branches are well garniſhed with large ſhining green leaves: they have an elegant appearance, and afford a kindly ſhade in hot countries, therefore are worthy of cultivation, in all thoſe countries where there is warmth enough to ripen the fruit.

As there are but few of the ſeeds in theſe fruit which come to perfection (for the greateſt part of them are abortive) ſo moſt of thoſe which have been brought to Europe have failed; therefore the ſureſt way to obtain the plants, is to ſow their ſeeds in tubs of earth in the country, and when the plants have obtained ſtrength, they may be brought to Europe; but there ſhould be great care taken in their paſſage, to ſcreen them from ſalt water and the ſpray of the ſea, as alſo not to give them much water, eſpecially when they are in a cool or temperate climate, for theſe plants are very impatient of wet. When the plants arrive in Europe, they ſhould be carefully tranſplanted, each into a ſeparate pot, filled with light kitchen-garden earth, and plunged into the tan-bed, obſerving to ſhade them from the ſun till they have taken new root; then they muſt be treated in the ſame manner as other tender plants from hot countries.

GARDENS are diſtinguiſhed into flower-gardens, fruit-gardens, and kitchen-gardens: the firſt, being deſigned for pleaſure and ornament, are to be placed in the moſt conſpicuous parts, i. e. next to, or juſt againſt the back front of the houſe; the two latter being principally intended for uſe and ſervice, are placed leſs in ſight.

Though the fruit and kitchen-gardens are here mentioned as two diſtinct gardens, and have by the French gardeners, as alſo by ſome of our own countrymen been contrived as ſuch, yet they are now uſually in one; and with good reaſon, ſince they both require a good ſoil and expoſure, and will equally require to be placed out of the view of the houſe. And as it will be proper to incloſe the kitchen-garden with walls, and to ſecure the gates, that no perſons may have acceſs to it, who have no buſineſs in it, for the ſake of preſerving the product, ſo theſe walls will anſwer the purpoſes of both. Moreover, in the diſpoſition of the kitchen-garden, when it is properly divided into quarters, the planting of eſpaliers of fruit-trees round each of the quarters, will be of uſe in ſcreening from the view the kitchen-herbs growing in the quarters; and, by that means, give an elegancy to both parts, and ſave beſides a great expence. The only objection which has been made to this of any conſequence is, that the gardeners are too apt to crowd the borders near the walls with kitchen-herbs, whereby the trees are deprived of their nouriſhment; but this is in every gentleman's power to redreſs, by not ſuffering the borders to be thus crowded. But I ſhall treat more fully of this under the article of Kitchen-Garden.

In the choice of a place to plan a garden in, the ſituation and expoſure of the ground are the moſt eſſential points to be regarded; ſince, if a failure be made in that point, all the care and expence will in a manner be loſt.

In a garden for pleaſure, the principal things to be conſidered, are, 1ſt, the ſituation; 2dly, the ſoil, aſpect, or expoſure; 3dly, water; 4thly, proſpect.

1ſt, Situation: this ought to be ſuch an one as is wholſome, in a place that is neither too high nor too low; for if a garden be too high, it will be expoſed to the winds, which are very prejudicial to trees; if it be too low, the dampneſs of the ground, the vermin, and venomous creatures that breed in ponds and marſhy places, add much to their inſalubrity.

A ſituation on a riſing ground, or on the ſide of a hill, is moſt happy, eſpecially if the ground be not too ſteep; if the ſlope be eaſy, and in a manner imperceptible; if a good deal of level may be had near the houſe; and if it abounds with ſprings of water; for, being ſheltered from the fury of the winds, and the violent heat of the ſun, a temperate air will be there enjoyed; and the water that deſcends from the top of the hills, either from ſprings or rain, will not only ſupply fountains, canals, and caſcades, for ornament, but when it has performed its office, will water the adjacent valleys, and render them fertile and wholſome, if it be not ſuffered to ſtagnate in them.

Indeed, if the declivity of the hill be too ſteep, and if the water be too abundant, a garden on the ſide of it may often ſuffer, by having the trees torn up by the torrents and floods; and the earth above tumbling down, the walls may be demoliſhed, and the walks ſpoiled.

It cannot however be denied, that the ſituation on a plain or flat, has ſeveral advantages that the higher ſituation has not: floods and rains make no ſpoil; there is a continued proſpect of champaigns, interſected by rivers, ponds, brooks, meadows and hills, covered with buildings or woods; and the level ſurface is leſs tireſome to walk on, and leſs chargeable, than that on the ſide of a hill; the terrace-walks and ſteps are not neceſſary; but the greateſt diſadvantage of flat gardens is the want of an extenſive proſpect, which riſing grounds afford.

2dly, The ſecond thing to be conſidered in chuſing a plat for a garden, is a good earth or ſoil.

It is ſcarce poſſible to make a fine garden in a bad ſoil; there are indeed ways to meliorate ground, but they are very expenſive; and ſometimes, when the expence has been beſtowed of laying good earth two feet deep over the whole ſurface, which for a large garden is an expence too great for moſt perſons; and after this a whole garden has been ruined, notwithſtanding the expoſure has been ſoutherly and healthful, when the roots of the trees have come to reach the natural bottom.

To judge of the quality of the ſoil, obſerve whether there be any Heath, Thiſtles, or ſuch like weeds, growing ſpontaneouſly in it, for they are certain ſigns that the ground is poor. Likewiſe if there be large trees growing thereabouts, obſerve whether they grow crooked, ill-ſhaped, of a faded green, and full of moſs, or infeſted with vermin; if ſo, the place is to be rejected: but on the contrary, if it be covered with good Graſs fit for paſture, then you may be encouraged to try the depth of the ſoil.

To know this dig holes in ſeveral places, ſix feet wide and four feet deep; if you find three feet of good earth it will do well, but leſs than two will not be ſufficient.

The quality of good ground is neither to be ſtony, nor too hard to work; neither too dry, nor too moiſt; nor too ſandy and light, nor too ſtrong and clayey, which is the worſt of all for gardens.

3dly, The third requiſite is water. The want of this is one of the greateſt inconveniencies that can attend a garden, and will bring a certain mortality upon whatever is planted in it, eſpecially in the greater droughts that often happen in a hot and dry ſituation in ſummer; beſides the uſefulneſs of it in fine gardens, for making jets d'eau, canals, caſcades, &c. which are the greateſt ornaments of a garden.

4thly, The fourth thing required in a good ſituation is, the view and proſpect of a fine country; and though this is not ſo abſolutely neceſſary as water, yet it is one of the moſt agreeable beauties of a fine garden: beſides, if a garden be planted in a low place that is buried, as I may ſay, and has no kind of proſpect, it will be not only diſagreeable but unwholſome, by being too much ſhaded and obſcured; as the trees will rather retain inſalubrious damps, than communicate the refreſhing air, that is ſo purifying to vegetable nature.

In ſhort, a garden neceſſarily requires (beſides the care of the gardener) the ſun, a good ſoil, a full, or at leaſt an open proſpect, and water, the laſt above all; and it would be egregious folly to plant a garden where any of theſe are wanting.

Of the Deſigning or Manner of Laying out a Pleaſure Garden.

The area of a handſome garden may take up thirty or forty acres, not more.

And as for the diſpoſition and diſtribution of this garden, the following directions may be obſerved.

1ſt, There ought always to be a deſcent from the houſe to the garden not fewer than three ſteps, but if there are ſix or ſeven it will be better. This elevation of the building will make it more dry and wholſome, alſo from the head of theſe ſteps there will be a farther proſpect or view of the garden.

In a fine garden, the firſt thing that ſhould preſent itſelf to the ſight, ſhould be an open lawn of Graſs, which, in ſize, ſhould be proportionable to the garden; in a large garden it ſhould not be leſs than ſix or eight acres; but in middling or ſmall gardens, the width of it ſhould be conſiderably more than the front of the houſe; and if the depth be one half more than the width, it will have a better effect. The figure of this lawn need not be regular, and if on the ſides there are trees planted irregularly, by way of open grove, ſome of which may be planted forwarder upon the lawn than the others, whereby the regularity of the lawn will be broken, it will render it more like nature, the beauties of which ſhould always be ſtudied in the laying out and planting of gardens; for the nearer theſe gardens approach to nature, the longer they will pleaſe; for what is a garden, but a natural ſpot of ground dreſſed and properly ornamented? there are thoſe who have erred in copying of what they call nature, as much as thoſe who have drawn a whole garden into ſtrait lines, great alleys, ſtars, &c. by bringing the rougheſt and moſt deformed part of nature into their compoſitions of gardens: as for inſtance, where the ground has been naturally level, they have at great expence, made hollows and raiſed mole-hills; ſo that the turf has been rendered not only more unpleaſant to walk upon, but much worſe to keep: and after all the pains that have been taken to ape nature, the whole is as eaſily diſcovered to be the work of art, as the ſtiffeſt ſlopes and the moſt finiſhed parterres.

The great art in laying out of gardens, is to adapt the ſeveral parts to the natural poſition of the ground, ſo as to have as little earth to remove as poſſible; for this is often one of the greateſt expences in making of gardens; and it may with truth be affirmed, that wherever this has been practiſed, nine times in ten it has proved for the worſe; ſo that if inſtead of levelling hills to form large terraces, ſtiff ſlopes, and even parterres, as have been too often practiſed; or the ſinking of hollows, and raiſing of hills, as hath by others been done; if the ſurface of the ground had only been ſmoothed and well turfed, it would have had a much better effect, and been more generally approved than the greateſt number of theſe gardens, which have been made with an infinite expence both of time and money.

The next thing to be obſerved is, to contrive a dry walk, which ſhould lead quite round the whole garden; for as gardens are deſigned to promote the exerciſe of walking, the greater the extent of this dry walk, the better it will anſwer the intent; ſince in bad weather, or in dewy mornings and evenings, when the fields are unpleaſant or unſafe to walk over, theſe dry walks in gardens become uſeful and pleaſant; and ſuch walks, if laid either with gravel or ſand, may lead through the different plantations, gently winding about in an eaſy natural way, which will be more agreeable than thoſe long ſtrait walks, which are too frequently ſeen in gardens.

But as the taſte of deſigning gardens has of late altered from the former method, there are many perſons who have gone into the oppoſite extreme; and in the forming of what they term ſerpentine walks, have twiſted them about in ſo many ſhort turns, as to render it very diſagreeable to walk on them; and at the ſame time they ſtrike the ſight with as much ſtiffneſs and appearance of art, as any of the methods formerly practiſed. In ſhort, the fewer turns there are in theſe walks, and the more they are concealed, the better they will pleaſe; and yet the turns being eaſy, and at great diſtances, will take off all the appearance of ſtraitneſs. And here let me obſerve, that there can be no better, or more eaſy or natural method of laying out theſe walks, than by tracing the eaſy turns made on a road, where it bends by the track of the coach wheels.

Theſe walks ſhould be ſo contrived, as to lead into ſhade as ſoon as poſſible; as alſo into ſome plantations of ſhrubs, where perſons may walk in private, and be ſheltered from the wind; for no garden can be pleaſing where there is want of ſhade and ſhelter.

Another thing abſolutely neceſſary is, where the boundaries of the garden are fenced with walls or pales, they ſhould be hid by plantations of flowering ſhrubs, intermixed with Laurels, and ſome other Evergreens, which will have a good effect, and at the ſame time conceal the fences, which are diſagreeable, when left naked and expoſed to the ſight.

In ſituations where there is a good ſupply of water, the deſigner has room for adding one of the greateſt beauties to the garden, eſpecially if it will admit of a conſtant ſtream; for in ſuch places, if the water is properly conducted through the garden, it will afford infinite pleaſure; for although theſe ſtreams may not be ſufficient to ſupply a large ſurface, yet if theſe narrow rivulets are judiciouſly led about the garden, they will have a better effect than many of the large ſtagnating ponds or canals, ſo frequently made in large gardens; for where theſe pieces of water are large, if all the boundaries can be ſeen from one point of view, they cannot be eſteemed by perſons of judgment; and frequently theſe ſtanding waters are brought ſo near the houſe, as to render the air damp and unhealthy; and many times they are ſo ſituated, as to occaſion this inconvenience, and at the ſame time are not ſeen to any advantage from the houſe.

Where wilderneſſes are intended, theſe ſhould not be cut into ſtars, and other ridiculous figures, nor formed into mazes or labyrinths, which in a great deſign is trifling, but the walks ſhould be noble, and ſhaded by tall trees; and the ſpaces of the quarters planted with flowering ſhrubs and Evergreens, whereby they will be rendered pleaſant at all ſeaſons of the year; and if there are hardy ſorts of flowers (which will thrive with little care) ſcattered about near the ſides of the walks, they will have a very good effect, in making a variety of natural beauties almoſt through the year.

The ſituation of theſe wilderneſſes ſhould not be too near the houſe, leſt they ſhould occaſion damps; therefore it is much better to contrive ſome open groves, through which there may be a communication under ſhade, from the houſe to theſe wilderneſſes; which are much the beſt when they are planted at the fartheſt part of the garden, provided they do not obſtruct the view of fine objects.

Buildings are alſo very great ornaments to a garden, if they are well deſigned and properly placed; but the modern taſte of crowding gardens with large uſeleſs buildings, I preſume to think is cenſurable, with regard as well to propriety as expence.

Statues and vaſes are alſo very beautiful objects, but theſe ſhould by no means be placed too near each other; for when ſeveral of them appear at once, they fill and confound the eye, and loſe the beautiful effect which they would have, if now and then one properly ſituated engages the ſight.

What an expence might be ſpared, and applied to nobler purpoſes, if nature only were to be imitated, if ſimplicity were ſtudied in this delightful art, rather than oſtentation! for any thing may be ſaid to be more of nature, than what we miſcall grandeur.

Fountains are alſo very ornamental to a garden, if they are magnificently built, and where a conſtant ſupply of water can be obtained; but if they are meanly erected, or have not water to keep them conſtantly running, they ſhould never be introduced into gardens, for nothing can be more ridiculous than to ſee a dry fountain; which, perhaps, at a great expence, may have water forced up, to ſupply it for an hour or two, and no more; and this perhaps not in dry ſeaſons, when there is a general ſcarcity of water.

The ſame may alſo be obſerved of caſcades, and other falls of water, which ought never to be contrived in gardens, where there cannot be a conſtant run of water; but where the ſituation of a garden is ſo happy, as to be naturally ſupplied with water, theſe falls and jet's d'eau, may be rendered very great beauties, eſpecially if they are well deſigned, and not made in the low mean taſte, in which too many of thoſe now in being appear, and where the water is made to fall over a parcel of regular ſteps of ſtone; but the fall ſhould be in one ſheet from top to bottom, where ſhould be placed many large rough ſtones to break and diſperſe the water, and to increaſe the noiſe of the fall.

Where the ground is naturally uneven, and has gentle riſes and falls, theſe may be ſo humoured in the laying out of the ground, as to be rendered very great beauties; but theſe inequalities of the ground muſt by no means be cut into regular ſtiff ſlopes, nor amphitheatres, as has been too much the practice: but if the knolls are properly planted with clumps of trees or ſhrubs, and the ſloping ſides ſmoothed and left in their natural poſition, they will have a much better effect, than can be given them by all the regular angles, lines, and flat ſlopes, which have been till of late, introduced by all the deſigners of gardens.

The taſte in laying out of gardens has greatly altered, and has been as greatly improved in England, in the compaſs of a few years; for, with the revolution, the Dutch taſte of laying out gardens was introduced, which conſiſted of little more than flower-borders laid out in ſeveral ſcrolls of Box-work, clipped Evergreens, and ſuch low expenſive things; as alſo the walling round, and dividing the ſeveral parts of gardens by croſs walls; ſo that a garden conſiſting of eight or ten acres, was generally divided by brick walls, into three or four ſeparate gardens; and theſe were reduced to exact levels, having many gravel-walks, and the borders on each ſide crowded with clipped trees and Evergreen hedges, dividing theſe ſmall incloſures again; ſo that the firſt making and planting of theſe ſmall gardens was attended with a greater expence, as was the keeping of them afterward, than gardens of ſix times the extent, when deſigned after nature.

Whether this taſte ſo univerſally prevailed in England, in complaiſance to his late Majeſty King William, or was owing to the low grovelling taſte of thoſe perſons, who had the deſigning of moſt of the Engliſh gardens, it is difficult to determine; but it is very certain, that the gentlemen, at that time, attended very little themſelves, to the diſpoſition of their gardens, but were contented to leave the whole direction of them to perſons of the meaneſt talents that ever profeſſed the art; ſo that ſoon after, when another taſte prevailed, theſe gardens were almoſt totally demoliſhed, and it would have been well, if a good, that is to ſay, a natural taſte had ſucceeded the other; but this was not the caſe; for though a more open and extenſive way of laying out gardens was introduced, yet this was little more than copying after the French, whoſe taſte was in making long avenues, ſtrait walks, ſtiff regular ſlopes, cabinets, fret-work, tall hedges cut into various ſhapes, jets d'eau, fountains, &c. ſo that there was little of nature ſtudied; but, on the contrary, all the geometrical figures introduced in wilderneſs-work, as alſo in the parterres, and other compartments of the garden: nor is it ſo much to be wondered at, that this taſte prevailed in France, when the deſigns of all the principal gardens were there formed by architects, who were as ſtudious to have the ſymmetry of the oppoſite, or correſponding part of the garden, as exact as the apartments of a habitation; nor has length of time, nor the improvements already made in other countries, amended their taſte, or convinced them of its abſurdity.

As the gardens of Verſailles, Marli, and others, were extolled for their magnificence, ſo the plans of them were almoſt univerſally copied; the deſigners, or imitators rather, only varying the parts according to the ſituation or figure of the ground; and this was practiſed for ſeveral years, at a time, when great ſums of money were expended in gardens, which might have rendered this country the moſt beautiful of any in Europe, had a natural taſte then prevailed in the deſigning of gardens; which is the more to be lamented, as the plantations then made, have been many of them rooted out, to make way for the alterations and improvements which have been ſince introduced.

Many perſons, I am ſenſible, will have it, that, in the deſigns of gardens, the taſte ſhould alter from time to time, as much as the faſhion of apparel; but theſe cannot be perſons of judgment; for whereever there are natural beauties in a country, they will always pleaſe perſons of real knowledge; and frequently it is obſerved, that perſons of but little ſkill in the art of gardening, are ſtruck with theſe beauties without knowing the cauſe; therefore where the beautiful parts of nature are juſtly imitated in gardens, they will always be approved by judicious perſons, let the taſte of gardening alter as it will.

When trees have been long growing in a garden, nothing can be more diſagreeable than to have them deſtroyed, to alter the garden according to the faſhion of the time, becauſe it requires much time to bring up trees to ſuch a height as to afford ſhade and ſhelter; and, as time is precious, ſo, where the diſpoſition of the garden is altered, there ſhould be great attention given to the preſervation of all the good trees, wherever they can be either uſeful or ornamental.

There is another eſſential part of gardening, which cannot be too much conſidered by perſons who deſign gardens, which is that of adapting the ſeveral ſorts of trees and ſhrubs, to the ſituation and ſoil of the garden, as alſo to allow the trees a proper ſhare of room; but, however neceſſary this will appear, yet very few perſons have made this their ſtudy, inſomuch that when one views many modern gardens, and ſees the great number of trees and ſhrubs, which are crowded into them, one would be induced to believe, that private intereſt has had a greater influence than any other motive, with the deſigners. Indeed this fault may often be aſcribed to the maſter, who, perhaps, is too much in haſte for ſhade and ſhelter, ſo will have three or four times the number of trees and ſhrubs planted as ſhould have been, or that can remain long without injury, where the plantations ſucceed; and to this over-haſte are owing the miſerable plantations of large trees, ſo often ſeen in gardens and parks, where trees of all ſorts, and of any age are taken out of woods, hedge-rows, &c. and removed at a great expence to ſtand and decay annually, till they become ſo many dead ſticks, than which nothing can be a more diſagreeable ſight to the owner; who, after an expectation for ſeveral years, attended with an expence of watering, digging, and cleaning, finds himſelf under a neceſſity either of replanting, or giving up the thoughts of having any. Numbers of perſons have indeed amuſed themſelves with the hopes of ſucceſs, by ſeeing theſe new planted trees put out branches for a year or two, which they generally do; but in three or four years after, inſtead of making a progreſs, they begin to decay at the top, and continue to do ſo gradually, until they quite periſh, which, perhaps, may not happen in eight or ten years, eſpecially if no ſevere winter, or very dry ſummer, intervenes, either of which generally proves fatal to theſe plantations; ſo that perſons may be led on with hopes, for ſo many years, in the beſt part of their lives, when there is a certainty of their failing, or at leaſt of their never increaſing in ſize; but of this I ſhall treat more fully in the article of Planting, and ſhall proceed.

In the buſineſs of deſigns, a mean and pitiful manner ſhould be ſtudiouſly avoided, and the aim ſhould be always at that which is noble and great, not to bring too many little things into a garden, nor to make ſmall pieces of water, narrow walks, &c. eſpecially in large gardens; for it is much better to have a few great things, than four times the number of ſmall ones, which are trifling. In ſmall gardens there is more excuſe for this, nor indeed would it be right, to have either large lawns, broad walks, or large pieces of water in ſuch; but yet even in theſe there ought to be a medium, and perſons ſhould never attempt to crowd too many things in theſe, whereby the whole will appear only as a mean and trifling model of a large garden.

Before the deſign of a garden is entered upon, it ought to be conſidered, what it will be in twenty or thirty years time, when the trees and ſhrubs are grown up, and ſpread; for it often happens, that a deſign, which looks handſome when it is firſt planted, and in good proportion, in proceſs of time becomes ſo ſmall and ridiculous, that there is a neceſſity either of altering or totally deſtroying it.

The general diſtribution of a garden, and of its parts, ought to be accommodated to the different ſituations of the ground, for a deſign may be very proper for a garden on a perfect level, which will by no means do for one where there are great inequalities in the ground; ſo that, as I have before intimated, the great art of deſigning is, in properly adapting the deſign to the ſituation, and contriving to ſave the expence of removing earth, to humour the inequalities of the ground, to proportion the number and ſorts of trees and ſhrubs to each part of the garden, and to ſhut out, from the view of the garden, no objects that may become ornamental.

There are, beſides theſe, many other rules relating to the proportions, conformity, and diſpoſition of the different parts and ornaments of gardens, of which more may be ſeen under their ſeveral articles.

GARDENIA. See Jasminum.

GARIDELLA. Tourn. Inſt. R. H. 655. tab. 430. Lin. Gen. Plant. 507. [This plant was ſo named by Dr. Tournefort, in honour of Dr. Garidel, who was profeſſor of phyſic, at Aix, in Provence.]

The Characters are,

The flower hath a ſmall, oblong, erect empalement of five leaves; it hath no petals, but five oblong equal nectariums occupy their place; theſe are bilabiate. The outer part of the under lip is bifid and plain; the interior part of the upper lip is ſhort and ſingle. The flower hath eight or ten awl-ſhaped ſtamina, which are ſhorter than the empalement, and are terminated by obtuſe erect ſummits. In the center is ſituated three germina, which are oblong, compreſſed, and ſharp-pointed, having no ſtyles, but crowned by ſimple ſtigmas; theſe become three oblong compreſſed capſules with two valves, incloſing ſeveral ſmall ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's tenth claſs, which includes thoſe plants whoſe flowers have ten ſtamina and three germen.

We know but one Species of this genus, viz.

Garidella (*Nigellaſtrum.*) Hort. Cliff. 170. Garidella foliis tenuiſſime diviſis. Tourn. *Garidella with very narrow divided leaves*; and the Nigella Cretica folio Fœniculi. C. B. P. 146. *Fennel-flower of Crete with a Fennel leaf.*

This plant is very near akin to the Nigella, or Fennel-flower, to which genus it was placed by the writers on botany before Dr. Tournefort, and was by him ſeparated from it, as differing in the form of the flower.

It grows wild in Candia, and on mount Baldus, in Italy, as alſo in Provence, where it was diſcovered by Dr. Garidel, who ſent the ſeeds to Dr. Tournefort, for the Royal Garden at Paris.

This is an annual plant, which riſes with an upright ſtalk a foot high, dividing into ſeveral ſlender branches, garniſhed at their joints with very ſlender leaves like thoſe of Fennel. The ſtalks are terminated by one ſmall flower, of a pale herbaceous colour, which is ſucceeded by three capſules, each containing two or three ſmall ſeeds. It flowers in June and July, and the ſeeds ripen in September. It is propagated by ſeeds, which ſhould be ſown in autumn, on a bed or border of light freſh earth, where the plants are deſigned to remain (for they ſeldom thrive if they are tranſplanted;) when the plants are come up, they muſt be carefully cleared from weeds, and where they are too cloſe, they muſt be thinned, leaving them about four or five inches apart; this is all the culture the plants require, and if the ſeeds are permitted to ſcatter, the plants will come up without any farther care.

GAULTHERIA.

The Characters are,

It hath a double permanent empalement; the outer has two oval, concave, ſhort leaves; the inner has one bell-ſhaped leaf cut into five ſegments; the flower has one oval petal, cut half-way into five ſegments, which are reflexed; it has ten awl-ſhaped nectarii, which are ſhort, ſurrounding the germen and ſtamina, and ten awl-ſhaped incurved ſtamina inſerted to the receptacle, terminated by bifid horned ſummits, and a roundiſh depreſſed germen, ſupporting a cylindrical ſtyle, crowned by an obtuſe ſtigma; the germen afterward becomes an obtuſe five-cornered capſule, having five cells, faſtened to the interior empalement, which turns to a berry open at the top, filled with hard angular ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's tenth claſs, intitled Decandria Monogynia, the flower having ten ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Gaultheria (*Procumbens.*) Amœn. Acad. 3. p. 14. *Trailing Gaultheria.* Vitis Idæa Canadenſis, pyrolæ folio. Tourn. Inſt. 608. *Canada Wortle-berry with a winter-green leaf.*

This plant grows naturally in ſeveral parts of North America upon ſwampy ground, ſo is with difficulty preſerved in the Engliſh gardens. The branches of this trail upon the ground, and become ligneous, but never riſe upward; they are garniſhed with oval entire leaves, placed alternate; the flowers are produced on the ſide of the branches; they are of an herbaceous colour, ſo make little appearance, and very rarely are ſucceeded by fruit in England.

The only method in which I have ſucceeded to keep this plant, was by planting of it in a pot, filled with looſe undunged earth, placing it in the ſhade, and frequently watering it; with this management I have kept the plant alive three years, and have had flowers but no fruit.

GAURA.

The Characters are,

It hath an empalement of one leaf, which falls off, with a long cylindrical tube, having four oblong glands faſtened to it; the upper part is cut into four oblong ſegments, which are reflexed. The flower hath four oblong riſing petals, which are broad at the top but narrow at their baſe, ſitting upon the tube of the empalement; and eight upright ſlender ſtamina which are ſhorter than the petals, and a nectarious gland between the baſe of each, with oblong moveable ſummits. The oblong germen is ſituated under the flower, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by four oval ſpreading ſtigmas; the flower is ſucceeded by an oval four-cornered compreſſed capſule, containing one oblong angular ſeed.

This genus of plants is ranged in the firſt ſection of Linnæus's eighth claſs, intitled Octandria Monogynia, the flower having eight ſtamina and one ſtyle.

We know but one Species of this genus, viz.

Gaura (*Biennis.*) Amœn. Acad. 3. p. 26. *Gaura.* Lyſimachia chamænerio ſimilis floridana, foliis nigris punctis capſulis carinatis in ramulorum cymis. Pluk. Amalth. 139. tab. 428. f. 1.

This is a biennial plant, which grows naturally in Virginia and Penſylvania: the ſtalk riſes four or five feet high, ſending out ſeveral branches, which are garniſhed with oblong, ſmooth, pale, green leaves, ſitting pretty cloſe. The flowers are produced in cloſe tufts at the end of the branches; they are compoſed of four oblong petals, of a pale Roſe colour, irregularly placed, having eight ſtamina ſurrounding the ſtyle. The flowers appear in September, and when the autumn proves favourable, the ſeeds will ripen toward the end of October.

If the ſeeds of this plant are ſown on open borders ſoon after they are ripe, they will more certainly ſucceed than when they are ſown in the ſpring. When the plants come up, they muſt be kept clean from weeds; and if they are too cloſe, ſome of them ſhould be drawn out, and planted in a bed to allow room for the other to grow; in the autumn they ſhould be all tranſplanted to the place where they are deſigned to ſtand for flowering and perfecting their ſeeds, and will require no other culture but to ſupport their branches to prevent the autumnal winds from breaking them down.

GENERATION is, by naturaliſts, defined to be the act of procreating and producing a thing which before was not; or, according to the ſchoolmen, it is the total change or converſion of a body into a new one, which retains no ſenſible part or mark of its former ſtate.

Thus we ſay, fire is generated, when we perceive it to be where before there was only wood, and other fuel, or when the wood is ſo changed, as to retain no ſenſible character of wood; in the like manner a chick is ſaid to be generated, when we perceive a chick, where before was only an egg, or the egg is changed into the form of a chick.

In generation there is not properly any production of new parts, but only a new modification or manner of exiſtence of the old ones, and thus generation is diſtinguiſhed from creation.

Generation alſo differs from alteration, in that in alteration the ſubject remains apparently the ſame, and is only changed in its accidents or affections, as iron, which before was ſquare, is now made round; or when the ſame body which is well to-day, is ſick to-morrow.

Again: generation is the oppoſite to corruption, which is the utter extinction of a former thing; as, when that which before was an egg, or wood, is no longer either the one or the other; whence it appears, that the generation of one thing is the corruption of another.

The Peripateticks explain generation by a change or paſſage from a privation, or want of a ſubſtantial form, to the having ſuch a form.

The moderns allow of no other change in generation, than what is local; and, according to their notion, it is only a tranſpoſition, or new arrangement of parts; and, in this ſenſe, the ſame matter is capable of undergoing an infinite number of generations.

As for example: A grain of Wheat, being committed to the ground, imbibes the humidity of the ſoil, becomes turgid, and dilates to ſuch a degree, that it becomes a plant; and, by a continual acceſſion of matter, by degrees, ripens into an ear, and at length into a ſeed; this ſeed, when ground in a mill, appears in the form of a flour, which, being mixed up with water, makes a paſte, of which bread is generated by the addition of yeaſt, and undergoing the operation of fire, i. e. by baking; and this bread being cominuted by the teeth, digeſted in the ſtomach, and conveyed through the canals of the body, becomes fleſh, or, in other words, fleſh is generated.

Now the only thing effected in all this ſeries of generation, is a local motion of the parts of the matter, and their ſettling again in a different order; ſo that wherever there is a new arrangement, or compoſition of the elements, there is, in reality, a new generation, and thus generation is reduced to motion.

Generation is more immediately underſtood of animal and vegetable bodies from ſeed, or the coition of others of different ſexes, but of the ſame genus or kind.

Monſ. Perrault, and ſome of the modern naturaliſts after him, maintained, That there is not properly any new generation, that God created all things at firſt, and that what is by us called generation, is no more than an augmentation and expanſion of the minute parts of the body of the ſeed; ſo that the whole ſpecies, which are afterwards produced, were, in reality, all formed at the firſt, and incloſed therein, to be brought forth and expoſed to view in time, and according to a certain order and œconomy.

And accordingly Dr. Garden ſays, It is moſt probable, that the ſtamina of all the plants and animals that have been formed, ab origine mundi, by the Almighty Creator, within the firſt of each reſpective kind; and he who conſiders the nature of viſion, that it does not give us the true magnitude, but only the proportion of things; and that which ſeems to our naked eye but a point, may truly be made up by as many parts as ſeem to be in the whole univerſe, will not think this an abſurd or impoſſible thing.

Dr. Blair, treating of the generation of plants, ſays, That when Almighty God created the world, he ſo ordered and diſpoſed of the materies mundi, that every thing produced from it ſhould continue ſo long as the world ſhould ſtand. Not that the ſame individual ſpecies ſhould always remain; for they were, in proceſs of time, to periſh, decay, and return to the earth, from whence they came; but that every like ſhould produce its like, every ſpecies ſhould produce its own kind, to prevent a final deſtruction of the ſpecies, or the neceſſity of a new creation, in order to continue the ſame ſpecies upon earth, or in the world.

For which end he laid down certain regulations, by which each ſpecies was to be propagated, preſerved, and ſupported, till, in order, or courſe of time, they were to be removed hence; for, without that, thoſe very beings, which were created at firſt, muſt have continued till the final diſſolution of all things, which Almighty God of his infinite wiſdom did not think fit.

But, that he might ſtill the more manifeſt his omnipotence, he ſet all the engines of his providence to work, by which one effect was to produce another by the means of certain laws, or rules laid down for the propagation, maintenance, and ſupport of all created beings; this his divine providence is called nature, and theſe regulations are called the laws, or rules of nature, by which it ever operates in its ordinary courſe, and whatever exceeds from that is ſaid to be preternatural, miraculous, or monſtrous.

Moſes, in his account of the creation, tells us, that plants have their ſeeds in themſelves, in theſe words: And God ſaid, Let the earth bring forth graſs, the herb yielding ſeed, and the fruit-tree yielding fruit, after his kind, whoſe ſeed is in itſelf upon the earth.

The antients, indeed, diſtinguiſhed the generation of animals into two kinds, i. e. into regular, called univocal; and anamolous, called alſo equivocal, or ſpontaneous.

The firſt was effected by parent animals of the ſame kind, as that of men, birds, beaſts, &c. The ſecond they ſuppoſed to be effected by corruption, the ſun, &c. as that of inſects, frogs, &c. but this latter is now generally exploded.

Many, indeed, have eſſayed to treat of the generation of animals, but few have been able to give that ſatisfactory account of it that were to be wiſhed for, and far fewer yet have been able to treat of the generation of plants as it ought to be; for that which ſtill kept them in the dark, was,

Firſt, That though there were two different ſexes in animals, by whoſe mutual aſſiſtance the ſpecies was propagated, yet there was no ſuch thing then known in plants.

Secondly, That though it can now be made appear, that every animal is produced by univocal generation, i. e. from an egg, and not by corruption, &c. as moſt of the antients imagined the inſects were; yet there are ſtill thoſe who maintain, that thoſe which they call imperfect plants, are the product of a certain rottenneſs in the earth.

The generation of plants bears a cloſe analogy to that of ſome animals, eſpecially ſuch as want local motion, as muſcles, and other immoveable ſhell-fiſh, which are hermaphrodite, and contain both the male and female organs of generation.

The flower of a plant is found to be the pudendum, or principal organ of generation; but the uſe of ſo much mechaniſm, and ſo many parts, has been but little known till of late years.

The flower of a Lily conſiſts of ſix petala, or flower-leaves, from the bottom of which, in the middle, ariſes a kind of tube, called by Tournefort, the piſtillum, and by Dr. Linnæus the ſtyle; this reſts upon the germen, which is the female organ of generation; round this are placed pretty fine threads, called the ſtamina, or filaments; theſe ſtamina ariſe likewiſe from the bottom of the flower, and terminate at the top in little ſummits, called by ſome apices, which are replete with a fine duſt, called farina; theſe are the male organs of plants.

This is the general ſtructure of the flowers of plants, although they are infinite ways diverſified, and to ſuch a degree, that ſome have no ſenſible piſtil, and others want the ſtamina; others again have the ſtamina, but want the apices, and ſome plants exceed all others in this, that they have no viſible flowers; but if it be allowed, that this before-mentioned is the moſt common ſtructure of flowers, it will follow, that theſe parts that ſeem wanting are uſually only leſs apparent, or are ſituated in different plants, or in different parts of the ſame plant.

The fruit is uſually at the baſe of the piſtillum, ſo that when the piſtillum falls with the reſt of the flower, the fruit appears in the ſtead of it; but oftentimes the piſtillum is the fruit itſelf, but ſtill they have both the ſame ſituation in the center of the flower, and the petala, or flower-leaves, which are diſpoſed around the little embryo, ſeem to be deſigned only to prepare a fine juice in the little veſſels, for the ſupport of it during the little time that they laſt, and it requires; but ſome ſuppoſe the chief uſe of them to be to defend the piſtillum, &c.

The apices of the ſtamina are ſmall capſulæ, or bags, full of a farina, or duſt, which falls out when the capſula grows ripe, and burſts.

Monſ. Tournefort ſuppoſed this duſt to be only an excrement of the food of the fruit, and the ſtamina to be nothing but excretory ducts, which filtrated this uſeleſs matter, and thus diſcharged the embryo; but Mr. Morland, Mr. Geoffroy, and others, find nobler uſes for this duſt; on their principle the ſtamina, with the apices and farina, make the male part of the plant, and the piſtil, the female.

Mr. Morland ſays, It hath been long ago obſerved, that there is in every particular ſeed a ſeminal plant conveniently lodged between the two lobes, which conſtitute the bulk of the ſeed, and are deſigned for the firſt nouriſhment of the tender plant.

But the admirable Dr. Grew, to whoſe generous induſtry, and happy ſagacity, we are indebted for the beſt improvements of this part of knowledge, is the only author I can find, who hath obſerved that the farina, or fine powder, which is, at its proper ſeaſon, ſhed out of thoſe thecæ, or apices ſeminiformes [i. e. ſeed-forming caſes] which grow at the top of the ſtamina, doth ſome way perform the office of male ſperm. But herein, I think, he falls ſhort, in that he ſuppoſes them only to drop upon the outſide the uterus, or vaſculum ſeminale, and to impregnate the included ſeed by ſome ſpirituous emanations, or energetical impreſs.

That which is now ſubjected to the diſquiſitions and cenſure of ſuch whoſe exquiſite ſkill conſtitutes them judges of ſuch performances, is, Whether it may not be more proper to ſuppoſe, that the ſeeds which are lodged in the proper involucra, are at the firſt unimpregnated ova (or eggs) as of animals; that this farina is a congeries of ſeminal plants, one of which muſt be conveyed into every ovum before it can become prolific; that the ſtylus, in Mr. Ray's language, or the upper part of the piſtillum, in Mr. Tournefort's, is a tube deſigned to convey theſe ſeminal plants into their neſts in the ova; that there is ſo vaſt a proviſion made, becauſe of the odds there are, whether one, of ſo many, ſhall ever find its way into, and through ſo narrow a conveyance.

To make this ſuppoſition the more credible, I ſhall lay down the obſervations I have made upon the ſituation of theſe ſtamina, and the ſtylus, in ſome few ſpecies of plants.

Firſt, In the Corona Imperialis, where the uterus, or vaſculum ſeminale of the plant ſtands upon the center of the flower; and from the top of this ariſeth the ſtylus, the vaſculum ſeminale and ſtylus together repreſenting a piſtillum.

Round this are placed ſix ſtamina; upon the ends of each of theſe are apices, ſo artfully fixed, that they turn every way with the leaſt wind, being in height almoſt equal to the ſtyles about which they play, and which in this plant is manifeſtly open at the top, as it is hollow all the way; to which we muſt add, that upon the top of the ſtylus there is a ſort of tuft, conſiſting of pinguid villi, which I imagined to be placed there to catch and detain the farina, as it flies out of the thecæ; from hence, I ſuppoſe, the wind ſhakes it down the tube, till it reach the vaſculum ſeminale.

In the Caprifolium, or Honeyſuckle, there riſes a ſtylus from the rudiments of a berry, into which it is inſerted to the top of the monopetalous flower; from the middle of which flower are ſent forth ſeveral ſtamina, that ſhed their farina out of the caſes upon the orifice of the ſtylus, which, in this plant, is villous or tufted, upon the ſame account as in the former.

In Allium, or common Garlic, there ariſes a tricoccous uterus, or ſeed-veſſel; in the center of which is inſerted a ſhort ſtylus, not ſo high as the apices, which thus over-topping it, have the opportunity of ſhedding their globules into an orifice more eaſily; for which reaſon, I can diſcern no tuft upon this (as in the former) to inſure their entrance, that being provided for by its ſituation juſt under them.

The reader, I hope, will excuſe me, if I preſent him now with ſome ſuch reaſonings or reflections as the foregoing account doth ſuggeſt, and will ſupport; and I cannot but hope to perſuade thoſe that are candid, that I have aſſigned to the ſeveral parts of the flowers I have mentioned, their true and real uſe.

For nothing can be more natural than to conclude, that where a fine powder is curiouſly prepared, carefully repoſited, and ſhed abroad at a peculiar ſeaſon, where there is a tube ſo placed as to be fit to receive it, and ſuch care in diſpoſing this tube, where it doth not lie directly under the caſes that ſhed the powder, it hath a particular apparatus at the end, to inſure its entrance.

Nothing can be more genuinely deduced from any premiſes, than it may from this, that this powder, or ſome of it, was deſigned to enter this tube. If theſe ſtamina had been only excretory ducts, as has been hitherto ſuppoſed, to ſeparate the groſſer parts, and leave the juice deſigned for the nouriſhment of the ſeed more reſerved, what need was there to lodge theſe excrements in ſuch curious repoſitories? They would have been conveyed any where, rather than where there was ſo much danger of their dropping into the ſeed-veſſel again, as there is here.

Again: the tube, over the mouth of which they are ſhed, and into which they enter, leads always directly into the ſeed-veſſel.

To which we muſt add, that the tube always begins to die when theſe thecæ are emptied of their contents; if they laſt any longer, it is only whilſt the globules, which enter at their orifice, may be ſuppoſed to have finiſhed their paſſage. Now, can we well expect a more convincing proof of theſe tubes being deſigned to convey theſe globules, than that they wither when there are not more globules to convey.

If I could now ſhew, that the ova, or unimpregnated ſeeds, are ever to be obſerved without this ſeminal plant, the proof would ariſe to a demonſtration; but having not been ſo happy as to obſerve this, I ſhall content myſelf at preſent with ſuggeſting, that hence one would conclude, that the petala of the flower were rather deſigned to ſever ſuperfluous juices from what was left to aſcend in the ſtamina, than the ſtamina to perform this office, either for them, or the unimpregnated ſemina, and obſerve the analogy between animal and vegetable generation, as far as was neceſſary there ſhould be an agreement between them. I ſhall recommend the enquiry to thoſe gentlemen who are maſters of the beſt microſcopes, and addreſs in uſing them; though, in the mean time, I have made ſome ſteps toward a proof of this ſort, and have met with ſome ſuch hints, as make me not deſpair of being able, in a ſhort time, to give the world even this ſatisfaction. For, not to inſiſt upon this, that the ſeminal plant always lies in that part of the ſeed which is always neareſt to the inſertion of this ſtylus, or ſome propagation of it into the ſeed-veſſels, I have diſcovered in Beans, Peas, and Kidney-beans, juſt under one end of that we call the eye, a manifeſt perforation, (diſcernible by the groſſer ſort of magnifying glaſſes) which leads directly to the ſeminal plant, and at which I ſuppoſe the ſeminal plant did enter; and, I am apt to think, the Beans or Peas that do not thrive well, may be found deſtitute of it.

But I muſt now proceed to deſcribe ſome other plants, whereby it will appear, that there is a particular care always exerciſed to convey this powder, ſo often mentioned, into a tube, which may convey it to the ova.

Now, in leguminous plants, if we carefully take off the petala of the flower, we ſhall diſcover the pod, or ſiliqua, cloſely covered with an involving membrane, which, about the top, ſeparates into nine ſtamina, each fraught with its quantity of farina; and theſe ſtamina cloſely adhere to the ſtyle, which is obſervable at the end of that tube, which here alſo leads directly to the pod; it ſtands not upright, indeed, but ſo bent, as to make near a right angle with it.

In Roſes there ſtands a column, conſiſting of many tubes cloſely clung together, though eaſily ſeparable, each leading to their particular cell, the ſtamina in a great number placed all round about.

In Tithymalus, or Spurge, there riſes a tricoccous veſſel, that, whilſt it is ſmall, and not eaſily diſcernible, lies at the bottom till it is impregnated, but afterwards grows up, and ſtands ſo high upon a tall pedicle of its own, as would tempt one to think, that there were to be no communication betwixt this and the apices.

In the Strawberries and Raſpberries, the hairs which grow upon the ripe fruit (which, I ſuppoſe, may be ſurpriſing to ſome) are ſo many tubes leading each to their particular ſeed; and therefore we may obſerve, that in the firſt opening of the flower there ſtands a ring of ſtamina, within the petala, and the whole inward area appears like a little wood of theſe hairs or pulp, which, when they have received and conveyed their globules, the ſeeds ſwell, and riſe in a carneous pulp. Thus far Mr. Morland.

We may obſerve a veſſel at the bottom of the piſtil of the Lily, which veſſel we may call the uterus, or womb, in which are three ovaries filled with little eggs, or rudiments of ſeed found in the ovaria, which always decay, and come to nothing, unleſs impregnated with the farina of the ſame plant, or ſome other of the ſame kind; the ſtamina alſo ſerve for the conveyance of the male ſeed of the plant to be perfected in the apices, which, when ripe, burſt forth in little particles like duſt; ſome of them fall into the orifice of the piſtil, and are either conveyed thence into the utricle, to fecundify the female ova, or lodged in the piſtil, where, by their magnetic virtue, they draw the nouriſhment from the other parts of the plant into the embryos of the fruit, making them ſwell, grow, &c.

In flowers that turn down, as the Cyclamen, and the Imperial Crown, the piſtil is much longer than the ſtamina, that their duſt may fall from their apices in ſufficient quantities on the piſtil, for the buſineſs of impregnation.

Mr. Geoffroy aſſures us, That in all the obſervations he had made, the cutting off the piſtil before it could be impregnated by the farina, actually rendered the plant barren for the ſeaſon, and the fruit abortive.

In many kinds of plants, as the Oak, Pine, Willow, &c. the flowers, Mr. Geoffroy obſerves, have their ſtamina and apices, whoſe farina may eaſily impregnate the rudiments of the fruit, which are not far off.

Indeed there is ſome difficulty in reconciling this ſyſtem with a certain ſpecies of plants, which bear flowers without fruit; and another ſpecies of the ſame kind and denomination, which bear fruit without flowers; ſuch are the Palm, Hemp, Hop, Poplar, &c. which are hence diſtinguiſhed into male and female; for how ſhould the farina of the male here, come to impregnate the ova of the female?

This difficulty Mr. Geoffroy ſolves, by ſuppoſing the wind to be the vehicle that conveys the male duſt to the female uterus, which is confirmed by an inſtance of Jovianus Potanus, of a ſingle female Palm-tree growing in a foreſt, which never bore fruit, till, having riſen above the other trees of the foreſt, and being then in a condition to receive the farina of the male by the wind, it began to bear fruit in abundance.

As to the manner wherein the farina fecundifies, Mr. Geoffroy advances two opinions:

Firſt, That the farina being always found of a ſulphureous compoſition, and full of ſubtil and penetrating parts (as appears from its ſprightly odour) which, falling on the piſtils of the flowers, there reſolves, and the ſubtileſt parts of it, penetrating the ſubſtance of the piſtil, excite a fermentation, which putting the latent juices of the young fruit in motion, occaſions the parts to unfold the young plant that is incloſed in the embryo of the ſeed.

In this hypotheſis, the plant in miniature is ſuppoſed to be contained in the ſeed, and to want only a proper juice to unfold its parts, and to make them grow.

The ſecond opinion is, That the farina of the male plant is the firſt germ or ſemen of the new plant, and ſtands in need of nothing to enable it to grow or unfold, but a ſuitable nidus with the juice it finds prepared in the embryo of the ſeed or ovary.

It may be obſerved, that theſe two theories of vegetable generation bear a ſtrict analogy to thoſe two of animal generation, viz. either that the young animal is in the ſemen maſculinum, and only ſtands in need of the juice of the matrix to cheriſh and bring it forth; or that the female ovum contains the animal, and requires only the male ſeed to excite a fermentation.

Mr. Geoffroy rather makes the proper ſeed to be in the farina, inaſmuch as the beſt microſcopes do not diſcover the leaſt appearance of any bud in the little embryos of the grains, when they are examined, before the apices have ſhed their duſt.

In leguminous plants, if the petala and ſtamina be removed, and the piſtil, or that part which becomes the pod, be viewed with the microſcope before the flower be open, thoſe little green tranſparent veſiculæ, which are to become grains, will appear in their natural order, yet ſtill ſhewing nothing elſe but the mere coat, or ſkin of the grain.

If you continue to obſerve the flowers as they advance for ſeveral days ſucceſſively, you will find them to ſwell, and, by degrees, to become replete with a limpid liquor; in which, when the farina comes to be ſhed, and the leaves of the flower to fall, there may be obſerved a little greeniſh ſpeck, or globule, floating about at large.

There is not at firſt any appearance of an organization in this little body; but in time, as it grows, you may begin to diſtinguiſh two little leaves like two ſmall horns; as the little body grows, the liquor diminiſhes inſenſibly, till at length the grain becomes quite opake; and upon opening it, the cavity will be found filled with a young plant in miniature, conſiſting of a little germ, or plantula, a little root, and the lobes of the Bean, or Pea.

The manner wherein this germ of the apex enters the veſicula of the grain, is not very difficult to determine: for, beſides that the cavity of the piſtil reaches from the top to the embryos of the grains, or thoſe veſiculæ, have a little aperture correſponding to the extremity of the cavity of the piſtil, ſo that the ſmall duſt, or farina, may eaſily fall, or find an eaſy paſſage in the aperture in the mouth of the veſſels, which is the embryo of the grain.

The aperture, or cicatricula, is much the ſame in both grains; and it is eaſily obſerved in Peas, Beans, &c. without a microſcope.

Dr. Patrick Blair, treating of the generation of plants, ſays, That a vegetative life is common to them, as well as animals; and that the propagation or production of the ſpecies is the effect of the vegetative, not the ſenſitive life in animals, as well as in plants; and that if there be a neceſſity of the concurrence of two different ſexes in animals, at the beginning or generating of the ſpecies, the ſame neceſſity muſt be in plants too; for as a cow, a mare, a hen, a ſhe-reptile, an inſect, &c. cannot produce an animal without the male, no more can it be ſuppoſed, that a plant can produce fertile ſeed without the concurrence of the male plant, or the male parts of the plant.

Mr. Ray ſays, That he will not deny, that both trees and herbs may produce fruit, and even come to maturity, without the male ſeed being ſprinkled upon them. For though moſt birds do not lay eggs without congreſs of the male, yet the hen often does it without copulating with the cock, but then theſe eggs are barren and wind eggs; juſt ſo, though a female plant may produce ſeed of itſelf, yet that ſeed is never fertile. For,

Firſt, As the work of generation in animals does not proceed from their animal or ſenſitive life but from their vegitative, which being the ſame as in plants, that operation muſt be performed after the ſame manner in both; therefore, as there is a neceſſity of two different ſexes in animals, it muſt be ſo too in plants.

Secondly, As paſſive ſeminal matter in female animals cannot be productive or fertile of itſelf, without being impregnated, animated, or its particles ſet in motion and dilated by the active principles of the male ſeminal matter; neither can the female ſeed in plants be rendered fertile, until it be impregnated by the farina fœcundans from the male parts of the plants.

As to the flowers of plants, if they were not aſſiſting to, or if there were not ſome extraordinary uſe from them in the perfection of the ſeed, they would not be ſo often obſerved upon plants as they are. But ſince there is no fruit or ſeed without a previous flower; and ſince where the one is obvious the other is conſpicuous, and ſince one is ſcarce to be obſerved with the naked eye, neither is the other; this implies a relation between them, that the one of them is not to be expected without the other.

It is true, there may be flowers upon a plant, where the fruit is ſeldom ſeen, eſpecially in theſe northern climates; ſuch as the Pervinca, the Nymphæa alba minima, and ſeveral others; where the plant exhauſts the nutritious juice, in puſhing forth tendrils or creeping roots, which ſo weaken the plants, as not to be able to bring the fruit to perfection; but there is no fruit or ſeed to be ſeen, unleſs a flower has been ſent as a meſſenger before it, to give notice of its approach; though it is not always upon the ſame plant, yet it is ſtill upon ſome other plant of the ſame ſpecies; for the flowers are to be ſeen upon diſtinct plants, different branches, or different parts of the branch from the fruit, in the Abies, Corylus, Nux Juglans, &c. the Mercurialis, Spinachia, &c.

But the fruit never appears, or never begins to increaſe upon theſe plants, till the flower is ſpent and gone; therefore they muſt ſerve for another uſe, than to be merely ornamental; for if that were their principal uſe, they would be always conſpicuous, which they are not for the moſt part in apetalous flowers; and they would always be to be ſeen, and never be hid; which is not ſo in the Aſarum, Hydrocotyle, &c. where, though the flower is large enough in proportion to the fruit, yet it is not to be ſeen, unleſs the leaf be turned up, and both flower and fruit be narrowly ſearched for.

The Frumenta and Gramina have their ſtamineous flowers; yet in ſome of them the flower is ſeldom to be ſeen, unleſs the ſpike be ſhaken; and then the apices will appear.

The Polypodium, and other capillary plants, have regular flowers, which precede the minute capſulæ or ſeed-veſſels, but neither of them are conſpicuous without a microſcope.

From theſe inſtances it appears, that the flowers are not conſtantly a guard to preſerve the tender embryos from the injuries of the air, for then the flowers muſt always have been upon the ſame pedicle with the fruit.

Therefore, ſince the appearance of the flower is the firſt ſtep towards the production of the ſeed, whether both be upon the ſame pedicle or not, it neceſſarily follows, that the one muſt contribute towards the bringing of the other to perfection.

The antients taking notice, that ſeveral plants did produce flowers and had no ſeeds, and that other plants of the ſame ſpecies, and ſown from the ſame ſeed, did produce the ſeed without a previous flower, they were ready to call the one male, and the other female, without any notion that the one was aſſiſting to the other; for they looked upon ſuch flowers to be only barren; and therefore they called thoſe which had flowers female, and thoſe that produced the fruits, male plants. Thus Mercurialis is called Spicata Fœmina, and Teſticulata Mas. That which produces the fruit muſt needs be the female, as the female animal brings forth the fœtus; therefore the teſticulata muſt needs be the female, and the ſpicata the male.

Wherever the plants are annual, theſe with the flowers, and ſuch as have the ſeed, are always near to each other; but where the root is perennial, and where the plant is more frequently propagated by the root than the ſeed, the caſe alters; for there being no need of the ſeed to propagate the plant, there is the leſs need of the flower to be nearer to the plant which produces the ſeed.

So the Spinachia and the Lupulus are frequently ſeen to grow, to produce the ſeed, and the other the ſquamous fruit; when the plants which produce the male flowers of the one or the other, are at ſome diſtance. And this is ſo far from being an objection againſt the neceſſity of two ſexes in plants as well as in animals, that it is an argument to confirm it; for it ſhews the wonderful contrivances in order to preſerve the ſpecies, when the ordinary means of propagating it by the ſeed cannot be ſo conveniently attained.

Theſe, and more that might be produced, being evident proofs of two ſexes in plants, as well as in animals, we ſhall in the next place, give ſome experiments to confirm this in a negative way, as have been already done in a poſitive.

When plants have been deprived of their male flowers, or male parts in the flower, they either produced no ſeed at all, or if they did, they became abortive, dried up, or dwindled away; or though the ſeeds did come to perfection, they were barren, or did not produce.

Experiment 1. Mr. Geoffroy having cut off all the ſtamineous tufts of male flowers from the top of the ſtalk in the Maiz or Turky-wheat, as ſoon as they appeared, and before the ſpike loaded with the embryos of the ſemen had put forth from the alæ of the leaves, ſeveral of theſe embryos decayed and dried up after they were pretty big; but ſome grains upon their pedicles all along the ſpike ſwelled conſiderably, and ſeemed to be full of the bud, and were conſequently fertile, while all the others miſcarried, and there was not one ſpike where the whole ſeeds did not ripen to the full.

This experiment is a ſufficient proof of the uſe of the male flowers of this plant; for whatſoever that is which flows from the racemi of theſe flowers, it ſeems it muſt be conducive not only for the impregnation of the ſeed, but alſo for the growth and impregnation of the fruit.

At preſent we ſhall ſhew, that what nouriſhment is uſually furniſhed by the pedicle to the embryos, does not appear to be capable to dilate or expand itſelf, or contribute to the continual ſupply of nutritious particles, unleſs the embryos were animated or enlivened by the ſpirit which ſhould have flowed from the male flowers; ſo that they were ſo debilitated and weakened, in aſcending from the body of the plant towards the embryos, before they could arrive at them, that they which otherwiſe might have ſerved for the augmentation and increaſe of all the embryos upon the ſpike, could not now do any thing more than contribute to the ripening of a few. And although Mr. Geoffroy might have imagined, that theſe few ſeeds which came to perfection were fertile alſo, becauſe they were full of germs, yet he could not be ſure of that, unleſs he had ſown the ſame ſeeds next ſeaſon, and tried whether they would chit or not.

Gardeners who buy Onion and Leek-ſeed brought from Straſburgh, commonly try the following experiment: they put a few of the ſeeds into a pot of water mixed with earth, and if they find they begin to ſpring, or ſend forth the ſeminal leaf or fibre of the root, after a few days, they judge of the product of it; and notwithſtanding all the ſeeds without this trial may ſeem to be productive, being equally firm, hard, and ſolid, perhaps not more than one third of them will prove fertile.

And this barrenneſs may proceed, either becauſe they had never been impregnated by the male parts of the flower, or that they had been too much expoſed to the air; being ſome time or other too much moiſtened, and not afterwards been carefully dried, or have been kept too long, by which neglect they loſe their ſpirit or life.

Now, if the fulneſs, ſolidity and firmneſs of a ſeed is not a ſure ſign of its fertility, then Mr. Geoffroy might have been miſtaken in his opinion of the fertility of theſe ſeeds in the Maiz, ſince he did not make any trial of it, by committing it to the ground.

In like manner, as to his ſecond experiment of the Mercurialis Dioſcoridis, where he raiſed ſome plants which had the fruit, and others which had the ſtamineous flowers, and removed the floriferous plants before the flowers were blown, every one of the ſeeds upon the fructiferous plants, except five or ſix, miſcarried; which ſeeds were ſo full, that he was perſuaded they were capable of producing new plants, and the like was found by Camerarius in the Cannabis. Yet inaſmuch as neither of them tried the experiment, by ſowing the ſame ſeed the ſecond year, they could not be ſure but that they might have failed in their expectation.

Mr. Bobart, overſeer of the phyſic-garden at Oxford, many years ſince, which was before the doctrine of the different ſexes of plants was well underſtood, being herbarizing, found a plant of the Lychnis ſylveſtris ſimplex, no apices; and taking notice that this was not only in one, but in all the flowers upon the ſame plant, he imagined it might be a new ſpecies; and therefore marked the plant, and took care to have it preſerved till the ſeeds were ripe; and then, they being full, hard, and firm, and to outward appearance full of germ, he ſowed them in a proper place in the garden the next ſeaſon, but not a plant ſprung up from them.

Theſe and other inſtances, ſet the opinion of the different ſexes of plants upon another footing than has been received by moſt of our modern authors; for it imports, that it is not the nouriſhment of the groſs ſubſtance of the ſeed itſelf which is hereby meant, nor the increaſe of the ſeed-veſſel, which is thereby deſigned; for (as is already obſerved) a hen can lay an egg, without having before had congreſs with a cock; and this, when newly laid, ſhall be of the ſame bigneſs, colour, taſte, and ſmell, with another egg which has been cocked (as they call it;) i. e. which has been fecundated by the maſculine ſeminal materies: but the difference will appear, when both are put under the hen, in order to be hatched; for the one ſhall pullulate or chit, and the other ſhall become fetid and rot.

The caſe is juſt the ſame with the ſeed of a plant, it may be augmented and increaſed in its bulk; it may become firm, hard, and ſolid, and have all the tokens of a perfect ripeneſs; the ſeed-veſſels may be enlarged, and the pulp or parenchyma of the fruit may be augmented; and yet the particles of the ſeed may remain crude, indigeſted, and incapable to be explicated and dilated, or ſet in a ſuitable motion, whereby to protrude the fibrilla of the root at one end, and the ſeminal leaves at the other; except it has before received ſome extraneous matter, or ſome active particles from the male parts of the flower, or from the male flower itſelf.

In order to confirm the neceſſity of two ſexes of plants, as well as in animals, this familiar conſideration may be added: that the fertility or barrenneſs of any tree, in the more or leſs fruitful ſeaſons, may be known to ignorant or leſs curious perſons, by the quantity of the flowers which appear in the ſpring time; and that not only in trees alone, where the flower and fruit are upon one and the ſame foot-ſtalk, but alſo in ſuch trees, where the flowers are upon diſtinct trees, or ſeparate places upon the ſame tree; for it is eaſy to determine by the catkins or iuli upon the Walnut, Filbert, or Hazle-trees, whether ſuch or ſuch trees will be fertile or barren for the enſuing ſeaſon, before any of the embryos begin to break, be puſhed forth, or appear.

Having already treated of the male and female parts of flowers, we ſhall next conſider their uſe.

Flowers, in this reſpect, may aptly be divided into that of male flowers, which (as has been before obſerved) were formerly reputed barren; and the plants which produce them were alſo called female plants, becauſe thoſe perſons not having any notion of different ſexes in plants, they were called female, upon account of their weakneſs; or if they had any thought of ſexes in them, it was only illuſive.

The ancients were ignorant of thoſe which are now-a-days called hermaphrodite flowers; and they, not having a true notion of ſexes of plants, could not imagine that the parts of both ſexes ſhould be in one flower, upon one and the ſame foot-ſtalk.

And although hermaphrodite animals bear the leaſt proportion in the animal kingdom, yet hermaphrodites have the greateſt ſhare in the vegetable, though they are not ſo numerous as they have been ſuppoſed to be; for upon a ſtrict examination it will be found, that a great many more plants have diſtinct male and female flowers, than was formerly believed.

The neceſſity of different ſexes in plants having been demonſtrated, and that the female ſeed, though it ſhould ripen to the full, cannot be fertile, except it be impregnated by what it receives from the male parts of flowers, we ſhall next explain the organs of generation in both ſexes.

In the animal œconomy, there are, beſides thoſe veſſels that are deſtinated for nutrition, and the ſecretion of the ſeveral juices in the body, ſpermatic veſſels, which conſiſt of præparantia, deferentia, and continentia ſemen. The præparantia in males, are the blood-veſſels and the teſtes; the one conveys the blood, and the other ſeparates the ſemen from blood, and elaborates it.

So likewiſe in plants there are veſſels that receive the nutritious particles from the earth, and convey it to the extremity of the plant; ſome of which tend directly to the leaf, and others to the flowers.

Thoſe which go to the foot-ſtalk of the flower may not improperly be called ſpermatic-veſſels, for it is from them that the ſeminal particles in male, female, and hermaphrodite flowers are ſeparated; therefore the foot-ſtalks of the hermaphrodite flowers are proportionably larger than thoſe either of the male or female; they have a double office, and contribute ſucceſſively to both.

In thoſe where the calyx becomes the fruit, the greateſt ſupply is furniſhed to it firſt, and diſtributed in its cortical parts, as is viſible in the Roſe; in which the foot-ſtalk is ſo far enlarged at firſt, as to be of an equal bigneſs with the bud.

After the calyx is thus formed, the next diſtribution is to the inner or centrical part of the flower, which Dr. Grew calls attire, and where the piſtillum becomes the fruit; the piſtillum and ſtylus are formed at the ſame time with the ſtamina and apices.

The ſtylus at the very firſt acquires both its due length and bigneſs; for the nutritious particles aſcending in the center never ſtop till the ſtylus is ſtretched out to its full length; and in ſuch as are furniſhed with a peculiar apex, that is formed firſt; the neck of the ſtylus, or that part next to it, is the biggeſt; from thence it gradually decreaſes in its groſſneſs, till it comes to the piſtillum. This is eaſily perceived by thoſe who will take the pains to open the bud of a Lily, Tulip, &c. before they are half blown.

The ſtamen is furniſhed next with an extraordinary ſupply of the nutritious particles before the flower is blown; theſe, whether fewer or more, are at firſt brought to their proportional largeneſs, being round and juicy.

The apex is the third which receives this extraordinary ſupply of the nouriſhment, for after that the ſtylus is formed, that it may lean to it after the veſſels of the ſtamen and ſummit are extended to their full length, and ſo formed, that they can convey ſuch an extraordinary quantity of particles as may fill up the capacity of the apex, it is then more enlarged than ever after; for if the flower of a Lily be opened before it be blown, the apex will be found to be full as long as the ſtamen; for as the one half of the apex covers the ſtamen, fixed to its center, ſo the other half of it is ſo far extended above the ſtamen, as the ſtamen remained uncovered below it, towards the pedicle or foot-ſtalk.

The fourth part of a flower is the petala, which receives this extraordinary ſupply of nouriſhment before the blowing; theſe upon the reverſe, are firſt enlarged towards the pedicle, and are afterwards extended and ſtretched forth in proportion to the enlargement of the attire; at firſt they are all groſſer, and more ſucculent towards the origin, and gradually become thinner and broader. The ſtamina of monopetalous flowers do, for the moſt part, ariſe partly from the petalon itſelf, and partly from the calyx; eſpecially if the ſtamina correſpond in number to the petala, as in the Hexapetalæ, or Polypetalæ Liliaceæ of Tournefort, where every ſtamen ariſes oppoſite to the middle of the petalon.

This obſervation (how and when this more than ordinary ſupply of nouriſhment is carried to the flowers) eaſily demonſtrates wherein the analogy of the organs of generation in plants and animals conſiſts.

In animals, the ſeminal matter is received by proper veſſels from the ſame blood from whence the other ſecretions, fit for the preſervation of the animal œconomy proceed; ſo that the blood in animals being the ſame with the ſap in plants, and both being conveyed after the ſame manner throughout the ſeveral bodies, it neceſſarily follows, that the one as well as the other, muſt have proper veſſels for ſecretion of the ſeminal matter.

Let it then be conſidered, that the ſap or nutritious juice aſcends in common to the pedicle of the flower, as the blood flows by the aorta deſcendens; and that at the calyx or bottom of the flower, ſome ſhare goes to one part of it, and ſome to another; as the aorta ſends one branch to the ſpermatic veſſels, and the remainder of it goes to perform the other functions; and as a part of the ſap is ſeparated by the pedicle of the flower, when the remainder is diſtributed throughout the remaining parts of the plant, ſo the arteria præparans goes directly to the teſtes in the males, and ovarium in the female: and in flowers ſome veſſels tend directly to the calyx (if it becomes the fruit) or to the perianthium (if there be any,) ſome to the petala, ſome to the ſtamina, ſome to the piſtillum or uterus, as it is called by Malpighius.

Theſe things being ſeriouſly reflected on, we muſt of neceſſity conclude,

1. That the ſame due care is taken to elaborate and prepare the more ſubtile and impenetrable particles of the nutritious juice in plants, as of the blood in animals.

2. This ſubſtance ſo prepared, as it muſt be deſigned for ſome extraordinary uſe, ſo this uſe can be no other than that of being the means of fecundating the female ſeed in plants, as the other is of the feminine oval in animals.

If any one ſhall take a flower full blown, and pull one of the ſtamina from the pedicle, he will find a rough viſcid liquor, like to the ſperma, which remains here till its moſt ſubtle parts have aſcended the ſtamen, or perhaps the more groſs particles might have remained there, after the moſt ſubtile had aſcended, before the flower was blown; this is as plain and demonſtrable as can be in the Lilies, particularly in the Orange Lily, and moſt of the Martagon Lilies, there is a contrivance more obvious.

This viſcid liquor aſcending by parallel ducts to the apex, there this ſubtile matter is retained till it is farther elaborated by the evaporations of the more humid and aqueous particles, by the heat of the ſun; and then it becomes a moſt ſubtile, fine, impalpable duſt, which is then ſaid to be ripe, and is called the farina.

Dr. Blair, after having given the ſentiments of ſeven different authors upon the ſubject, proceeds to give his own, without ſubſcribing to the ſentiment of either the one or the other; and endeavours by a ſtrict examination of the flowers themſelves, to find out which of theſe two opinions, ſo diametrically oppoſite to each other, are moſt agreeable to fact.

But before he begins, he lays down this general maxim, which he takes for granted, that nature is uniform in all her operations, and never recedes from thoſe rules laid down by the wiſe Diſpoſer of all things at the creation, by performing the ſame thing after two different and contrary methods; and thence concludes, that if the farina be a congeries of ſeminal plants in one ſpecies, it muſt be ſo in all.

If there be an open and direct paſſage, or though it be not ſo direct, yet if by any direct paſſage, by which it can be demonſtrated, that one ſingle grain of the farina can enter every individual ſeed in one plant, it muſt be ſo in all; but if neither of theſe hold good, and if it can be proved by ocular inſpection, without the aſſiſtance of a microſcope, in thoſe very plants exemplified by Mr. Morland, Mr. Geoffroy, and Mr. Bradley, that the farina in ſubſtance cannot enter the ſeminal veſſel; or if it does, that there is no direct paſſage for it to enter each particular ſeed, after it has ſo got into the capſula or ſiliqua; then he hopes, both their queries, ſuppoſitions, and aſſertions, muſt fall.

As for the Corona Imperialis, the firſt example given by Mr. Morland, the flower of which hangs downwards, though he does not deny but its ſtylus may be hollow all the way, and that it may be open at the extremity, yet by its ſituation, and ſeveral other circumſtances, it does not ſeem to him to favour this opinion.

For firſt, as there is a continual conflux of particles through the ſkin in animal bodies, it is alſo ſo in vegetables: this appears by the immediate fading of flowers, or any other part of the plant, after it has been plucked off; which proceeds from the evaporation of the particles in the little tubes, without any more ſucceeding in their place.

He thinks it as reaſonable to ſuppoſe, that theſe particles flow out by the hollow ſtylus, as by any other part, and alſo more ſenſibly there than elſewhere, becauſe of their being concentrated within ſuch narrow bounds; and that if theſe particles deſcend by the ſtylus hanging downwards, the particles, or rather grains of the farina, can never aſcend the ſame way.

2dly, That if it ſhould be granted, that theſe grains did aſcend by the ſtylus, how do they get into the ſeminal veſſel; that being cloſely ſhut up, as will appear to any one who ſhall obſerve it.

3dly, Whereas Mr. Morland ſuppoſes, that the rain either waſhes it, or the wind ſhakes it down the tube, till it reaches the ſeminal veſſel; Dr. Blair obſerves, that the extremity which is the upper part of the ſtylus in an erect flower, muſt be the lower in a dependent one; ſo that if either the rain or wind have acceſs to it, it muſt neceſſarily either waſh or drive it away from the ſeminal veſſel, which is now the ſtylus.

But here the Doctor takes notice of another contrivance, for anſwering that purpoſe, i. e. a ſort of a pelvis or ciſtern, called by Linnæus nectarium, ſituated at the origin or root of each petalon, filled with a viſcous liquor which continues there, and never exceeds its bounds ſo long as the petalon is in health: for ſince the apices are here ſo artfully fixed, that they turn every way with the leaſt wind, as Mr. Morland rightly obſerves, when they burſt, and the farina is driven to and fro, though it cannot ſo eaſily enter the tube, yet it may conveniently be blown up towards the orifice of the petala ſurrounding the ſtylus, where it is ſtopped or ſtaid by this viſcoſity, till it has performed its office.

To confirm this, he inſtances Mr. Fairchild, who, he ſays, being perſuaded that this viſcous liquor did ſome way or other contribute towards the fructifying of this plant, but not underſtanding how it did ſo, he tried the experiment, by wiping this liquor off as ſoon as it was depoſited in the pelvis, and the flower which he ſo ſerved did not bear any fruit.

And the way the doctor accounts for this is, that the humidity being removed, the farina is no ſooner blown upwards, than it immediately falls down, without producing any effect; and that which he takes to be a confirmation of this is, that both Tulips and Fritillarias have this pelvis or baſon, yet it is for the moſt part dry and empty; becauſe the flowers of the former being erect, they have no ſuch need of this liquor to retain the duſt; for that the rain, having immediate acceſs to them, may waſh the duſt towards the origin of the petala, where it can remain till it has performed its office; whereas the rain having no acceſs to the inner ſurface of the flower of the Corona Imperialis, it is naturally endowed with this humidity, depoſited there by ſeveral excretory ducts, in order to render it fit for the purpoſe: and Malpighius himſelf takes notice of this ſingularity in this flower, though he aſcribes no uſe to it.

The next example propoſed by Mr. Morland, is the Yellow Lily, which, according to his figure, is repreſented as having the apices equally high with the top of the ſtylus, and the petala over-topping each other; whereas he ſays, that by the narroweſt inſpection he ever could make, the top of the apices (they being then perpendicularly ſituated) reaches no higher than the neck of the button upon the top of the ſtylus, and that this is before the apices begin to burſt and ſhed the duſt; but as ſoon as the flower begins to open, they depart from the ſtylus, and force the petala outwards, by a certain elaſticity, and expand themſelves; this being done, they immediately change their poſture from a perpendicular to an oblique or horizontal one; nor do they ever pour out their duſt or farina, till they can conveniently drop it upon the bottom of the flower, and towards the root of the piſtillum.

But taking it for granted that it was ſo, the top of the ſtylus (which the Doctor calls the button, in oppoſition to the apices ſtaminum,) he ſays, is ſo compact, and of ſo firm a ſubſtance, that it is next to impoſſible, that the farina in ſubſtance, or in integral parts, can paſs through it.

If the integral parts, the complete grain, the minute globuli, in which the whole ſeminal plant is contained, cannot then enter, the whole compound muſt be diſſolved, and the minute ſeminal particles in this ſmall grain of duſt muſt be diſunited; and if ſo, how ſhall theſe again come to cement, ſo as to make up one continued body? or how ſhall this little body, ſo united, penetrate a ſecond time the partition-wall betwixt the ſtylus and piſtillum? and again, how ſhall it find out its way to its neſt, in the proper embryo of the ſeed?

The Doctor takes notice of the White Lily, the Orange Lily, the Martagon Lily, &c. as objections to the opinions of Mr. Morland, Bradley, &c. and alſo mentions the Iris, as a moſt pregnant inſtance, that the farina cannot ſo much as come at the piſtillum; for having ſix petals, the three ſtamina with long apices lie hid between the three petala which hang downwards, and three large expanſions of the bifid ſtylus, and the upper part of the down-hanging petalon: the farina can never reach the center of the ſtylus, though it were hollow, which it is not, but muſt deſcend along its outſide, to the top and outſide of the rudiment of the fruit, there to emit its effluvia. Theſe and other inſtances he concludes, are ſufficient proof, that the farina cannot enter the ſtylus, penetrate into the piſtillum, or inner part of the ſeminal veſſel, nor have the leaſt acceſs to the embryo of the ſeed.

As to the objection, that there is not paſſage ſufficient to admit the male ſeed into the uterus, or even into the ovaries, it is thus anſwered:

If it be conſidered how every flower, when it is prepared for the act of receiving the male ſeed, is ſo much under the influence of the ſun, that the petals open at its approach, and ſhut up again at its departure, it very well explains how the piſtillum, or female parts of generation, are relaxed at one time more than another, i. e. that the female parts are more relaxed at the opening of the flower, than when the flower is ſhut up; for the flower-leaves adhering to the bottom of the piſtillum, muſt conſequently, when they bend back, put every part of the piſtillum into a different poſture to that in which it was when the petals were ſhut.

And it is certain, that it is the preſence of the ſun that ripens the male duſt in the apices, and opens the little caſes in which it is contained, giving them a ſpringineſs that flings forth that duſt as ſoon as it is ripe, ſo as to ſcatter it to a conſiderable diſtance. The female parts are at this time dilated by the opening of the flower-leaves, and the apices and chives, concurring at the ſame time in flinging forth their male duſt, anſwer the ſame end in the generation of plants, that the act of copulation does among animals.

Having thus given ſeveral reaſonings and arguments uſed by various authors, who have made it their ſtudy to inveſtigate the mode of generation of vegetables, whether the impregnation of them proceeds from the farina fœcundans, or male duſt, entering the uterus of plants in ſubſtances, or by effluvia, I ſhall not take upon me to determine the diſpute; eſpecially ſince Mr. Boyle has proved, that all effluvia are ſubtile particles of matter; ſo that it matters not how ſmall or minute theſe particles are, ſince a body in its firſt ſtate may be ſo minute as to be ſcarcely perceptible.

I ſhall therefore conclude with mentioning a few experiments of my own, which I communicated to Dr. Patrick Blair, which he improved as a proof of his opinion of effluvia; and Mr. Bradley alſo, as a proof of the farina entering the uterus in ſubſtance, and leave the curious enquirer to determine on that ſide of the queſtion, to which reaſoning and experiment ſhall influence him.

I ſeparated the male plants of a bed of Spinach from the female; and the conſequence was, that the ſeed did ſwell to the uſual bigneſs, but when ſown it did not grow afterwards; and ſearching into the ſeed, I found it wanted the punctum vitæ, or what Geoffroy calls the germen.

I ſet twelve Tulips by themſelves, about ſix or ſeven yards from any other, and as ſoon as they blew, I took out the ſtamina with their ſummits ſo very carefully, that I ſcattered none of the male duſt; and about two days afterwards I ſaw bees working on a bed of Tulips, where I did not take out the ſtamina; and when they came out, they were loaded with the farina or male duſt on their bodies and legs; and I ſaw them fly into the Tulips, where I had taken out the ſtamina, and when they came out, I found they had left behind them ſufficient to impregnate theſe flowers, for they bore good ripe ſeeds which afterward grew.

In a parcel of Savoys, which were planted for ſeed near white and red Cabbages, the ſeeds, when ſown, produced half red, and ſome white Cabbages, and ſome Savoys with red ribs, and ſome neither one ſort nor the other, but a mixture of all ſorts together in one plant, which I ſuppoſe might happen by the effluvia of the different ſorts impregnating the uterus of each other.

In a letter communicated by Paul Dudley, Eſq; to the Royal Society, written from New England, he mentions the interchanging of the colours of the Indian Wheat, if the various colours are planted in rows near each other; but if they are planted ſeparately, they conſtantly keep to their own colour; and this interchanging of colours has been obſerved, when the diſtance between the rows of Corn has been ſeveral yards, though he ſays, if there happens to be a high board fence between the different coloured Corns, the alteration of colours is entirely prevented.

It is from different flowers impregnating each other, that the ſeveral varieties have been produced; and this gives new light to the floriſts, for raiſing a much greater variety of flowers; for by planting the different coloured flowers near each other, ſo that the flowers when fully blown may be intermixed, their farina will impregnate each other, ſo that the ſeeds will produce variegated flowers partaking of both colours. But it muſt be obſerved, that flowers of different genera will not impregnate each other, therefore the plants muſt be of the ſame genus which are placed together.

Cucumbers and Melons always produce male and female flowers upon different parts of the ſame plant; the male flower (which appears upon a ſlender footſtalk, and has a large ſtyle in the middle, covered with an Orange-coloured farina) is by the gardeners commonly called falſe bloſſoms, and are ſometimes by unſkilful perſons pulled off ſoon after they appear, ſuppoſing that they weaken the plants, if ſuffered to remain, which is a very great miſtake; for, in order to try this experiment, I planted four holes of Melons in a place pretty far diſtant from any other; and when the flowers began to appear, I conſtantly pulled off all the male flowers from time to time before they opened; the conſequence was, that all the young fruit dropt off ſoon after they appeared, and not one ſingle fruit remained to grow to any ſize, though the vines were equally ſtrong with thoſe which I had planted in another place, where I ſuffered all the flowers to remain upon them, from which I had a great quantity of fruit. But this doctrine is now ſo well eſtabliſhed among the gardeners, being confirmed by experience, that they now carry the male flowers of the Cucumbers and Melons to the female, if there are none ſituated very near them, and gently ſtrike the farina o the male, into the boſom of the female flowers, and thereby ſet the young fruit, which would otherwiſe drop off.

There are ſome perſons, who ſtill object to this theory of the generation of plants, from having obſerved ſome plants, which were termed female, growing ſingly, and at a very great diſtance from any male plants of the ſame kind, which had for ſome years produced ſeeds which were perfect, and grew when ſown; and indeed I was myſelf a little ſtaggered in my opinion, on having obſerved a female plant of the white Briony, which grew ſingly in a garden, where there were no other plants of the ſame kind; which for ſeveral years produced berries, which grew and flouriſhed perfectly well. This put me upon examining the plant more carefully than I had before done, when I found there were great numbers of male flowers intermixed with the female, on the ſame plant; and ſince then I have frequently found the ſame in many other plants, which are ſometimes male and female in different plants, yet have ſometimes both ſexes on the ſame plant; ſo that the objections which have been made to this doctrine, may not have proper evidence for their ſupport.

It is certain, that the female plants may produce fruit, without the impregnation of the male; but it is not certain, that this fruit or ſeed will, if ſown, produce another plant. What has been ſo often related by travellers and hiſtorians, of the neceſſity of the male Palm-tree being near the female, in order to render it fruitful, hath been fully confirmed by Father Labat, in his account of Africa, where he has treated of the ſeveral ſorts of Palms: he ſays, that he obſerved in Martinico a large Palm-tree, which grew by the ſide of a convent, which produced plenty of fruit, though there was no other Palm-tree growing within two leagues of this; but he alſo obſerved, that none of theſe fruit would grow, though they had made many trials of them; ſo that they were obliged to procure ſome fruit from Barbary, in order to propagate theſe trees. He likewiſe adds, that the fruit which grew on this female tree, never ripened ſo perfectly, nor was ſo well taſted, as thoſe which came from trees which had ſtood near ſome of the male: therefore we may conclude, that the fruit or ſeed may be produced by the female plants of moſt kinds, without the aſſiſtance of the male ſperm, which may appear to ſight perfect, and fit to produce others; but if we examine the ſeeds, we ſhall find that moſt of them have not the germ or little plant incloſed, nor will grow if they are ſown.

From theſe and many other experiments, it is very plain, that there is a neceſſity that the embryo of the female flower ſhould be impregnated by the farina or male duſt, in order to render the fruit perfect; but how, or in what manner it is performed, is what we can only gueſs at, ſince in the generation of animals, our greateſt naturaliſts differ very much in their opinions; nor can any of them aſcertain any particular method how it is performed. I ſhall therefore conclude with quoting the words of the Rev. Dr. Hales, which are a moſt ingenious ſummary of the whole doctrine of the generation of plants.

"If I (ſays he) may be allowed to indulge conjecture " in a caſe in which the moſt diligent enquirers are, " as yet, after all their laudable reſearches, advanced " but little farther than mere conjecture, I would " propoſe it to their conſideration, whether from the " manifeſt proof we have, that ſulphur ſtrongly attracts air, a hint may not be taken, to conſider " whether this may not be the primary uſe of the farina fœcundans, to attract or unite with elaſtic or " other refined active particles. That this farina " abounds with ſulphur, and that a very refined ſort, " is probable from the ſubtile oil which chymiſts obtain from the chives of Saffron; and if this be the " uſe of it, was it poſſible that it could be more aptly " placed for the purpoſe on very moveable apices " fixed on the ſlender points of the ſtamina, whereby " it might eaſily, with the leaſt breath of wind, be " diſperſed in the air, thereby ſurrounding the plant, " as it were, with an atmoſphere of ſublimed ſulphureous pounce? for many trees and plants abound " with it, which uniting with the air particles, may, " perhaps, be inſpired at ſeveral parts of the plant, " and eſpecially at the piſtillum, and be thence conveyed to the capſula ſeminalis, eſpecially towards " evening, and in the night, when the beautiful petala of the flowers are cloſed up, and they, with all " the other parts of the vegetable, are in a ſtrongly " imbibing ſtate. And if to theſe united, ſulphureous " and aereal particles, we ſuppoſe ſome particles of " light to be joined (for Sir Iſaac Newton has found, " that ſulphur attracts light ſtrongly;) then the reſult of theſe three by far the moſt active principles " in nature, will be a punctum ſaliens to invigorate " the ſeminal plant; and thus we are at laſt conducted, by the regular analyſis of vegetable nature, " to the firſt enlivening principle of their minuteſt " origin."

GENISTA. Lin. Gen. Plant. 766. Tourn. Inſt. R. H. 643. tab. 412. Broom; in French, *Genêt*.

The CHARACTERS are,

The empalement of the flower is of one leaf, tubulous, and divided into two lips; the upper lip is deeply cut into two, and the under into three equal parts. The flower is of the butterfly kind; the ſtandard is oval, acute, and remote from the keel, being wholly reflexed; the wings are a little ſhorter than the ſtandard, and are looſe: the keel is erect, and longer than the ſtandard, and is indented at the top. It hath ten ſtamina joined in two bodies, which are ſituated in the keel, terminated by ſingle ſummits. In the center is an oblong germen, ſupporting an aſcending ſtyle, crowned by an acute twiſted ſtigma. The germen afterward becomes a roundiſh turgid pod with one cell, opening with two valves, incloſing kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, which includes the plants with flowers having ten ſtamina, joined in two bodies; and to this he adds ſome of Tournefort's ſpecies of Spartium, and the Geniſtella of Tournefort.

The SPECIES are,

1. GENISTA (*Sagittalis*) ramis ancipitibus articulatis, foliis ovato-lanceolatis. Hort. Cliff. 355. *Jointed Broom, with two-edged branches, and jointed, oval, ſpear-ſhaped leaves.* Chamæ Geniſta ſagittalis. C. B. P. 395. *Dwarf arrow-ſhaped Broom.*
2. GENISTA (*Florida*) foliis lanceolatis, ramis ſtriatis teretibus racemis ſecundis. Hort. Cliff. 355. *Broom with ſpear-ſhaped leaves, and erect taper branches abounding with flowers.* Geniſta tinctoria Hiſpanica. C. B. P. 395. *Spaniſh Dyers Broom.*
3. GENISTA (*Tinctoria*) foliis lanceolatis glabris ramis ſtriatis teretibus erectis. Hort. Cliff. 355. *Broom with ſpear-ſhaped leaves which are acute, and taper channelled branches proceeding from the ſide of the ſtalk.* Geniſta tinctoria Germanica. C. B. P. 395. *Common Dyers Broom, or Wood-waxen.*
4. GENISTA (*Purgans*) ſpinis terminalibus, ramis teretibus ſtriatis, foliis lanceolatis ſimplicibus pubeſcentibus. Lin. Sp. 999. *Broom with taper-ſtreaked branches terminated by ſpines, and ſimple, ſpear-ſhaped, hairy leaves.* Geniſta ſive ſpartium purgans. J. B. 1. p. 404.
5. GENISTA (*Candicans*) foliis ternatis ſubtus villoſis, pedunculis lateralibus ſubquinquefloris foliatis, leguminibus hirſutis. Amœn. Acad. 4. p. 284. *Trifoliate Broom with hairy leaves, foot-ſtalks from the ſide of the branches having five flowers, and hairy pods.* Cytiſus Monſpeſſulanus, medicæ folio, ſiliquis denſe congeſtis & villoſis. Tourn Inſt. 648.
6. GENISTA (*Tridentata*) ramis triquetris ſubarticulatis, foliis tricuſpidatis. Lin. Sp. Plant. 710. *Broom with three-cornered jointed branches, and leaves ending in three points.* Geniſtella fruticoſa Luſitanica. Tourn. Inſt. 646. *Shrubby Portugal Dyers Broom.*
7. GENISTA (*Piloſa*) foliis lanceolatis obtuſis, caule tuberculato decumbente. Hort. Cliff. 355. *Broom with*

obtuſe ſpear-ſhaped leaves, and a declining ſtalk having tubercles. This is the Geniſta ramoſa, foliis Hyperici. C. B. P. 395. *Branching Broom with leaves like St. Johnſwort.*

8. Genista (*Anglica*) ſpinis ſimplicibus, ramis floriferis inermibus, foliis lanceolatis. Hort. Cliff. 355. *Broom with ſingle ſpines, flower-branches without ſpines, and ſpear-ſhaped leaves.* Geniſta ſpartium minus Anglicum. Tourn. Inſt. R. H. 645. *Small Engliſh Broom, called Petty Whin.*

9. Genista (*Hiſpanica*) ſpinis decompoſitis, ramis floriferis, inermibus, foliis lanceolatis. Lin. Sp. Plant. 711. *Broom with decompounded ſpines, flower-branches without ſpines, and narrow hairy leaves.* Geniſta ſpinoſa minor Hiſpanica villoſiſſima. C. B. P. 395. *Moſt hairy, ſmall, Spaniſh, prickly Broom.*

The firſt ſort grows naturally in France, Italy, and Germany. This plant ſends out ſeveral ſtalks from the root, which ſpread flat on the ground, and divide into many flat branches which are jointed, and their two ſides are edged like a broad ſword; theſe are green and herbaceous, but are perennial. At each of the joints is placed one ſmall ſpear-ſhaped leaf, without any foot-ſtalk. The flowers are produced in cloſe ſpikes at the end of the branches; they are yellow, and of the Pea-bloom kind, and are ſucceeded by ſhort hairy pods, which contain three or four kidney-ſhaped ſeeds. The plants flower in June, and the ſeeds ripen in September.

This ſort is propagated by ſeeds, which, if ſown in the autumn, the plants will come up the following ſpring; but when they are ſown in the ſpring, the plants rarely come up the ſame year: when the plants come up, they will require no other culture but to keep them clean from weeds, and thin them where they are too cloſe; at Michaelmas they may be tranſplanted where they are deſigned to remain, and after that they will only require to be kept clean, for they are very hardy, and will live ſeveral years.

The ſecond ſort riſes with ligneous ſtalks about two or three feet high, ſending out many taper channelled branches which grow erect, garniſhed with ſmall ſpear-ſhaped leaves placed alternate, and are terminated by ſeveral ſpikes of yellow flowers, which are of the Pea-bloom kind; theſe are ſucceeded by ſhort pods, which turn black when ripe, and contain four or five kidney-ſhaped ſeeds. It flowers in June and July, and the ſeeds ripen in autumn.

The third ſort grows naturally in England. This hath ſhrubby ſtalks, which riſe about three feet high, garniſhed with ſpear-ſhaped leaves, which are broader, and end in ſharper points than thoſe of the former; the branches come out from the ſide of the ſtalks, almoſt their whole length, and do not grow ſo upright as thoſe of the ſecond; theſe are terminated by looſe ſpikes of yellow flowers, which are ſucceeded by pods like thoſe of the ſecond ſort. It flowers, and the ſeeds are ripe about the ſame time as the former. The branches of the plant are uſed by the dyers, to give a yellow colour, from whence it is called Dyers Broom, Green-wood, Wood-waxen, or Dyers-weed.

The fourth ſort grows naturally about Montpelier. This riſes with ſhrubby, ſtriated, taper ſtalks four feet high, ſending out ſeveral branches which are terminated by ſpines; the leaves are ſpear-ſhaped, ſingle, and hairy; the flowers are produced in ſpikes at the end of the branches, they are larger than thoſe of the other ſorts, and are of a paler yellow colour. They appear in June and July, and are ſucceeded by pods like the former ſorts.

This ſort is tender, and in ſevere froſts is often killed in England, where the plants are not protected.

The fifth ſort grows naturally about Montpelier. This riſes with a woody ſtalk to the height of ſeven or eight feet, ſending out many ſlender branches, garniſhed with trifoliate leaves, hairy on their under ſide; the upper part of theſe branches, for more than a foot in length, ſend out ſmall flowering branches on their ſide, ſupporting five yellow flowers. Theſe appear in June and July, and the ſeeds ripen in autumn.

The ſixth ſort hath a low ſhrubby ſtalk, which ſeldom is more than a foot high, ſending out ſeveral weak branches which are jointed, garniſhed with ſmall leaves ending in three acute parts. The flowers are produced in looſe ſpikes at the top of the branches, they are of a pale yellow colour, and appear the latter end of June and in July, and the ſeeds ripen in September. This plant grows naturally in Portugal.

The ſeventh ſort hath a ſhrubby ſtalk which declines toward the ground, and is ſet over with tubercles; it divides into a few ſmall branches, which are garniſhed with ſmall obtuſe leaves. The flowers are diſpoſed in ſmall looſe ſpikes at the end of the branches; they are ſmall, of a pale yellow colour, and are ſucceeded by ſhort pods filled with kidney-ſhaped ſeeds. It flowers in June, and the ſeeds ripen in autumn. This grows naturally in Germany and France.

The eighth ſort grows naturally upon open heaths in many parts of England. It hath a ſhrubby ſtalk which riſes about two feet high, ſending out many ſlender branches, which are armed with long ſingle ſpines, and garniſhed with very ſmall ſpear-ſhaped leaves, placed alternate on every ſide the branches: the flower-branches have no ſpines; theſe are ſhort, and have five or ſix yellow flowers growing in a cluſter at the end. They come out in April and May, and are ſucceeded by ſhort turgid pods, which contain four or five ſmall kidney-ſhaped ſeeds. Theſe ripen in July.

The ninth ſort grows naturally in Spain. This hath a low ſhrubby ſtalk, which ſends out many ligneous branches, armed with branching thorns, compoſed of ſeveral ſharp thorns, which come out from each other, but the ſhort branches which produce the flowers have no ſpines; theſe are garniſhed with ſmall hairy leaves of different forms, ſome of them being as narrow as hairs, and others are of the ſpear-ſhape; the branches are terminated by cluſters of yellow flowers, which are ſucceeded by ſhort, compreſſed, hairy pods, filled with kidney-ſhaped ſeeds. The whole plant has much the appearance of the common Furz or Gorſe, but is very hairy, and the flower-branches being without thorns, are the moſt obvious diſtinctions.

All theſe ſorts of Brooms are propagated by ſeeds, which, if ſown in the autumn, will ſucceed much better than if ſown in the ſpring, and a year will be thereby ſaved; as theſe plants ſend out long, ſtringy, tough roots, which run deep into the ground, they do not bear tranſplanting well, eſpecially if they are not removed young; therefore the beſt way is to ſow a few ſeeds in thoſe places where the plants are deſigned to remain, and to pull up all except the moſt promiſing plants as ſoon as they are paſt danger; after this the plants will require no other culture, but to keep them clean from weeds: but where this cannot be practiſed, the ſeeds may be ſown thin upon a bed of light earth, and when the plants come up, they muſt be kept clean from weeds till the following autumn, when the plants ſhould be carefully taken up and tranſplanted where they are deſigned to remain.

They are all very hardy plants except the fourth, fifth, and ninth ſorts, which muſt have a warm ſheltered ſituation and dry ſoil, otherwiſe they will not live through the winter, but the others will grow in almoſt any ſoil or ſituation.

GENISTA SPINOSA, the Furz, Whins, or Gorſe. See Ulex.

GENTIANA. Lin. Gen. Plant. 285. Tourn. Inſt. R. H. 80. tab. 40. [takes its name from Gentius, a king of Illyrium, who firſt diſcovered the virtues of this plant.] Gentian, or Fellwort; in French, *Gentiane.*

The Characters are,

It hath a permanent empalement, which is cut into five acute ſegments. The flower hath one petal, which is tubulous, cut into five parts at the top, which are flat. It hath

hath five awl-ſhaped ſtamina, which are ſhorter than the petal, terminated by ſingle ſummits. In the center is ſituated an oblong cylindrical germen, having no ſtyle, but is crowned by two oval ſtigmas. The germen afterward becomes an oblong taper-pointed capſule, with one cell, containing many ſmall ſeeds faſtened to the valves of the capſule.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, which includes the plants whoſe flowers have five ſtamina and two ſtigmas.

The Species are,

1. Gentiana (*Lutea*) corollis quinquefidis rotatis verticillatis, calycibus ſpathaceis. Hall. Helv. 479. *Gentian with quinquefid wheel-ſhaped petals growing in whorls, and hood-like empalements.* Gentiana major lutea. C. B. P. 187. *Greater yellow Gentian.*
2. Gentiana (*Pneumonathe*) corollis quinquefidis campanulatis oppoſitis pedunculatis, foliis linearibus. Lin. Sp. Plant. 228. *Gentian with bell-ſhaped quinquefid petals placed oppoſite upon foot-ſtalks, and very narrow leaves.* Gentiana anguſtifolia autumnalis major. C. B. P. 188. *Greater narrow-leaved autumnal Gentian.*
3. Gentiana (*Aſclepiades*) corollis quinquefidis campanulatis oppoſitis ſeſſilibus, foliis amplexicaulibus. Lin. Sp. Plant. 227. *Gentian with bell-ſhaped quinquefid petals ſitting cloſe to the ſtalk oppoſite, and leaves embracing the ſtalk.* Gentian Aſclepiades folio. C. B. P. 187. *Gentian with a Swallow-wort leaf.*
4. Gentiana (*Acaulis*) corollâ quinquefidâ campanulatâ, caulem excedente. Lin. Sp. Plant. 228. *Gentian with a bell-ſhaped quinquefid petal exceeding the ſtalk.* Gentiana Alpina latifolia, magno flore. C. B. P. 187. *Broad-leaved Alpine Gentian with a large flower, commonly called Gentianella.*
5. Gentiana (*Nivalis*) corollis quinquefidis infundibuliformibus, ramis unifloris alternis. Lin. Sp. Plant. 229. *Gentian with funnel-ſhaped quinquefid petals, and alternate branches having one flower.* Gentiana annua, foliis Centaurii minoris. Tourn. Inſt. 81. *Annual Gentian with leſſer Centaury leaves.*
6. Gentiana (*Cruciata*) corollis quadrifidis imberbibus verticillatis ſeſſilibus. Lin. Sp. Plant. 231. *Gentian with quadrifid petals without beards, growing in whorls cloſe to the ſtalks.* Gentiana cruciata. C. B. P. 188. *Croſſwort Gentian.*
7. Gentiana (*Cilliata*) corollis quadrifidis margine ciliatis. Lin. Sp. Plant. 231. *Gentian with a four-pointed petal, whoſe border is hairy.* Gentianella cærulea oris piloſis. C. B. P. 188. *Blue Gentian with hairy brims.*
8. Gentiana (*Utriculoſa*) corollis quinquefidis hypocrateriformibus, calycibus plicatis alatis. Lin. Sp. Plant. 229. *Gentian with ſalver-ſhaped quinquefid petals, and winged plaited empalements.* Gentiana utriculis ventricoſis. C. B. P. 188. *Gentian with a ventricoſe tube.*
9. Gentiana (*Centaureum*) corollis quinquefidis infundibuliformibus caule dichotomo. Lin. Sp. Plant. 229. *Gentian with a funnel-ſhaped, five-pointed petal, and a forked ſtalk.* Centaurium minus. C. B. P. 278. *Leſſer Centaury.*
10. Gentiana (*Perfoliatum*) corollis octifidis, foliis perfoliatis. Lin, Sp. Plant. 232. *Gentian with an eight-pointed petal, and Thorough-wax leaves.* Centaurium luteum perfoliatum. C. B. P. 278. *Yellow perfoliate Centaury.*
11. Gentiana (*Spicata*) corollis quinquefidis floribus alternis ſeſſilibus. Lin. Sp. Plant. 230. *Gentian with funnel-ſhaped five-pointed petals, flowers growing alternate, and ſitting cloſe to the ſtalks.* Centaurium minus ſpicatum album. C. B. P. 278. *Leſſer Centaury with a white ſpiked flower.*
12. Gentiana (*Exaltata*) corollis quinquefidis coronatis crenatis, pedunculo terminali longiſſimo dichotomo. Lin. Sp. 331. *Gentian with a five-pointed petal, a very long foot-ſtalk, and forked branches.* Centaurium minus maritimum amplo flore cæruleo. Plum. Cat. 3. *Leſſer maritime Centaury with a large blue flower.*

The firſt ſort is the common Gentian of the ſhops, whoſe root is one of the principal ingredients in bitters.

This plant has a large thick root of a yellowiſh brown colour, and a very bitter taſte; the lower leaves are of an oblong oval ſhape, a little pointed at the end, ſtiff, of a yellowiſh green, and have five large veins on the back of each, and are plaited. The ſtalk riſes to the height of three or four feet, which is garniſhed with leaves, growing by pairs at each joint, almoſt embracing the ſtalk at their baſe; theſe are of the ſame form with the lower, but diminiſh gradually in their ſize to the top. The flowers come out in whorls at the joints, toward the upper part of the ſtalks, ſtanding on ſhort foot-ſtalks, whoſe origin is from the wings of the leaves; theſe are of a pale yellow, and have one petal, which is divided almoſt to the bottom, having an oblong cylindrical germen, which afterward ſwells to an oblong taper capſule, which is bifid at the point, and opens in two cells, filled with ſmall ſeeds.

It grows naturally in the paſtures in Switzerland, and in the mountainous parts of Germany, from whence the roots are brought to England for medicinal uſe; there is a compound water, and an extract made of them. The root of the Gentian is alſo one of the principal ingredients in bitters, and is frequently uſed in many diſorders.

But a few years ago, there was a mixture of Henbane roots brought over with Gentian, which was unhappily uſed, and occaſioned great diſorders in the perſons to whom it was adminiſtered; upon which great enquiry was then made to find out what that root could be, ſome ſuſpecting it to be the root of Deadly Nightſhade, and others believing it to be ſome of the poiſonous umbelliferous roots, but on comparing it with ſome dried roots of the Henbane, I found they were the ſame. We have likewiſe an account of the noxious quality of theſe roots, printed in the Synopſis Stirpium Hibernicarum, which was communicated to the author by Dr. Thomas Molyneux, phyſician to the ſtate; it was as follows:

The Dean of Clonfert was making ſome alterations in his garden, and, looking over his workmen, he obſerved them to dig up many roots, which he took for Skirrets, and therefore ordered ſome of them to be carried in and dreſſed for dinner, which was accordingly done; but all thoſe who eat of them were in a ſhort time ſeized with dizzineſs in their head, ſickneſs at the ſtomach, attended with an unuſual heat and drineſs in their throats; and two, who had eaten a larger ſhare than the reſt, loſt the uſe of their reaſon, and became delirious, which continued for ſome days; and as it appeared evident theſe diſorders were occaſioned by the roots, the Dean cauſed ſome of them to be planted, that he might be aſſured what the plant was whoſe roots had this bad quality; and in the ſpring, when they put out their leaves, they proved to be the Henbane, which has been noticed by old writers to be poſſeſſed of theſe qualities. And as the diſorders which were occaſioned by theſe ſuppoſed Gentian roots, were nearly the ſame, as is above related, I thought it might be of uſe to inſert it here, to caution others againſt eating of roots which they are unacquainted with.

This plant delights in a light loamy ſoil and a ſhady ſituation, where it will thrive much better than in a light dry ſoil, or in an open expoſure. It is propagated by ſeeds, which ſhould be ſown in pots ſoon after it is ripe, for if it is kept till the ſpring, it will not ſucceed; theſe pots ſhould be placed in a ſhady ſituation, and kept clean from weeds. In the ſpring the plants will appear, when they muſt be duly watered in dry weather, and kept clean from weeds till the following autumn; then they ſhould be carefully ſhaken out of the pots, ſo as not to break or injure their roots; and a ſhady border of loamy earth ſhould be well dug and prepared to receive them, into which the plants ſhould be planted at about ſix inches diſtance each way, obſerving to let the top of the roots be a little below the ſurface of the ground, then preſs the earth cloſe to the roots; after this they will require no farther care, but to keep them conſtantly clean from weeds; and if the following ſpring ſhould prove dry, they ſhould be duly watered, which will greatly forward their growth. In this border the plants may ſtand two years, by which time they will be fit to tranſplant where they are deſigned to remain; therefore in autumn, ſo ſoon as their leaves decay, they may be removed; but as the roots of theſe plants run deep into the ground, like Carrots, there muſt be great care taken in digging them up, not to cut or break their roots, for that will greatly weaken, if it does not kill them. After the plants are well fixed in their places, they require no other culture, but to dig the ground about them early in the ſpring before they begin to ſhoot, and in the ſummer to keep them clean from weeds. The roots of theſe plants will continue many years, but the ſtalks decay every autumn; the ſame roots do not flower two years together, nor ſeldom oftener than every third year; but when they flower ſtrong, they make a fine appearance; and as theſe delight in ſhady moiſt ground, where but few ornamental plants will thrive, ſo they ſhould not be wanting in good gardens.

The ſecond ſort grows naturally in moiſt paſtures in many parts of England, but particularly in the north; this riſes with an upright ſtalk about a foot high, garniſhed with ſmooth leaves an inch and a half long, and leſs than a quarter of an inch broad; they are placed oppoſite, and have no foot-ſtalks. The flowers are produced on the top of the ſtalk, three or four in number, ſtanding upon foot-ſtalks alternately above each other; they are large, bell-ſhaped, and divided into five points at their brim, and are of a deep blue colour, ſo make a fine appearance; theſe come out the latter end of July in the warm parts of England, but in the north they are full a month later.

It may be propagated by ſeeds in the ſame manner as the firſt ſort, and the plants may be treated in the ſame way; but as this ſort does not ſhoot its roots deep into the ground, it may be tranſplanted with leſs hazard; however, if theſe are removed with a ball of earth to their roots, they will not feel their removal ſo much as when the earth is all taken from them. This ſort ſhould be planted in a ſtrong, moiſt, loamy ſoil, in which the plants will thrive and flower annually, but in a warm dry ſoil they will not thrive or flower.

The third ſort grows naturally upon the Helvetian mountains; this riſes with an upright ſtalk near a foot high, garniſhed with ſmooth leaves about two inches long, and three quarters of an inch broad at their baſe, where they embrace the ſtalk, but they end in acute points; they are placed oppoſite, and are of a fine green, and diminiſh in their ſize as they are nearer the top; they have five longitudinal veins, which join at both ends, but diverge from each other in the middle. The flowers come out by pairs oppoſite, from the bottoms of the leaves, ſtanding on ſhort foot-ſtalks; they are pretty large, bell-ſhaped, and of a fine blue colour, ſo make a fine appearance when they are open. This ſort flowers in June and July.

It may be propagated by ſeeds in the ſame manner as the firſt ſort, and the plants may be treated in the ſame way, but they muſt have a moiſt loamy ſoil, otherwiſe they will not thrive. It may alſo be propagated by offsets, which may be divided from the roots; theſe ſhould be taken off in autumn, which is the beſt ſeaſon for removing all theſe ſorts of plants; but theſe ſhould not be removed, or parted oftener than every third year, where they are expected to produce ſtrong flowers.

The fourth ſort grows naturally on the Alps and Helvetian mountains, but has been long cultivated in moſt of the curious gardens in Europe; this is commonly known by the title of Gentianella. It is a low plant, the ſtalks ſeldom growing more than three or four inches high; they are garniſhed with ſmooth leaves placed oppoſite, which are two inches long, and half an inch broad, ſitting cloſe to the ſtalk. The flowers grow erect on the top of the ſtalk, ſo ſtand quite above them; theſe are often ſingle, but ſometimes, when the plants are ſtrong, there will be four or five at the end of each ſtalk; they are large, bell-ſhaped, and of a deep azure blue, ſo is the fineſt of that colour of any flower yet known. It uſually flowers in May, but ſometimes the plants flower again in autumn.

This is commonly propagated by parting of the roots, in the ſame manner as is before directed for the third ſort, but theſe muſt not be often tranſplanted, or parted, if they are wanted to flower ſtrong; this ſort ſhould have a ſoft loamy ſoil and a ſhady ſituation, where the plants will thrive and flower well every year.

It may alſo be propagated by ſeeds, which, in a good ſoil, the plants will produce in plenty; theſe ſhould be ſown in autumn, in the ſame manner as is before directed for the firſt ſort; and if the plants are planted in a good ſoil, they will be ſtrong enough to flower the ſecond year after they come up, and theſe ſeedling plants will flower much ſtronger than thoſe which are propagated by offsets.

The fifth and eighth ſorts are low annual plants, which grow naturally upon the Alps and other mountainous places in Europe, and are very rarely cultivated in gardens. The fifth ſeldom riſes more than two inches high, branching out from the root into ſeveral ſlender ſtalks, garniſhed with very ſmall leaves placed by pairs, and each ſtalk is terminated by one ſmaller blue flower ſtanding erect. The eighth ſort grows about four inches high, with a ſingle upright ſtalk of a purple colour. The leaves at the root are oval, but thoſe upon the ſtalk are narrow, and ſtand oppoſite. The ſtalk is terminated by one blue flower, with a large bellied empalement, which is plaited, and the petal of the flower riſes but a little above the empalement, ſo does not make much appearance. After the top flower decays, there are frequently two ſmaller flowers which come out from the ſide of the ſtalk, at the two upper joints; theſe flower after each other, the upper one coming firſt, ſo that there is a ſucceſſion of flowers till autumn.

As theſe plants uſually grow upon moiſt ſpongy ground, it is very difficult to cultivate them in gardens; for unleſs they have a ſoil approaching near to that in which they naturally grow, they will not thrive; the only method to obtain them is, either to ſow their ſeeds in pots, or upon a moiſt boggy ground in autumn, but it muſt be in the ſhade; and when the plants come up, they may be thinned, and the ſurface of the ground about them covered with moſs, which ſhould be conſtantly kept moiſt; with this management I have ſeen the plants thrive and flower very well.

The ſixth ſort is a perennial plant, which grows naturally upon the Appenines and the Helvetian mountains; this riſes with an upright ſtalk about ſix inches high, garniſhed with ſmooth ſpear-ſhaped leaves about two inches long, and one broad in the middle, ſitting cloſe to the ſtalk; they are placed oppoſite, and each pair of leaves croſs one another, from whence it is called Croſſwort Gentian. The flowers are produced in whorls round the ſtalks at the upper joints, ſitting very cloſe to the ſtalks, and at the top there is a large cluſter growing in the ſame form; theſe are of a light blue colour, and appear in May. This may be propagated by ſeeds, or offsets, in the ſame manner as the third and fourth ſorts, and the plants muſt be treated in the ſame way.

The ſeventh ſort grows naturally upon the Alps, and other mountainous parts of Europe; this is a low perennial plant, whoſe ſtalks are very ſlender, and rarely riſe more than three or four inches high, garniſhed with ſmall, narrow, acute-pointed leaves, placed in pairs; each ſtalk is terminated by one large blue flower, which is hairy on the inſide at the brim. This flowers in July and Auguſt, and may be propagated and treated in the ſame manner as the third and fourth ſorts.

The ninth ſort is the Leſſer Centaury of the ſhops; this grows naturally upon dry paſtures in moſt parts of England, where it riſes in height proportionable to the goodneſs of the ſoil; for in good land it is frequently a foot high, but in poor ſoils not more than three or four inches. It is an annual plant, with upright branching ſtalks, garniſhed with ſmall leaves placed by pairs. The flowers grow in form of an umbel at the top, and are of a bright purple colour; they come out in July, and the ſeeds ripen in autumn. This plant cannot be cultivated in the gardens.

The tenth ſort grows naturally upon chalky grounds in many parts of England. It is an annual plant, riſing with an upright ſtalk a foot high, garniſhed with oval-pointed leaves, whoſe baſe ſurrounds the ſtalk; they grow by pairs, and are of a gray colour; the ſtalks and leaves are very ſmooth. The flowers grow in form of an umbel on the top of the ſtalk; they are of a bright yellow colour, and are cut into eight parts at the top. Theſe appear in July, and the ſeeds ripen in autumn.

The eleventh ſort is an annual plant, which grows naturally in the ſouth of France and in Italy; this riſes with an upright ſtalk about a foot high, ſending out ſeveral branches toward the top, which are garniſhed by ſmall leaves placed oppoſite. The flowers are produced from the ſide and at the top of the ſtalk, in form of looſe irregular umbels; they are white, and about the ſize of thoſe of the common Centaury.

The twelfth ſort grows naturally in the Weſt-Indies, where it was diſcovered by Father Plumier, and the late Dr. Houſtoun found it growing in plenty at La Vera Cruz, in low moiſt places where the water ſtagnates, but at a remoter diſtance from the ſea. The ſeeds of this plant he ſent to England, which ſucceeded in the Chelſea garden; this riſes with an upright branching ſtalk near two feet high, garniſhed with oblong, ſmooth, acute-pointed leaves, placed oppoſite; the upper part of the ſtalk divides into ſeveral forks, between which are ſix or ſeven long naked foot-ſtalks, each ſuſtaining one large blue flower, divided into five ſegments at the brim. The flowers are ſucceeded by oblong capſules with one cell, filled with ſmall ſeeds.

This is propagated by ſeeds, which muſt be ſown on a hot-bed ſoon after they are ripe, and the plants afterward treated in the ſame manner as other tender annual plants from warm countries, being too tender to thrive in the open air in England. If the ſeeds of this plant are ſown in autumn, in pots placed in the tan-bed of the ſtove, they will ſucceed better than when they are ſown in the ſpring, and the plants will flower early, ſo good ſeeds may be obtained.

GENTIANELLA. See GENTIANA.

GERANIUM. Lin. Gen. Plant. 346. Tourn. Inſt. R. H. 266. tab. 142. [takes its name from Γέρανος, *Gr.* a crane, or ſtork, becauſe its fruit reſembles the bill of a Crane.] *Crane's-bill*; in French, *Bec de Gruë*.

The CHARACTERS are,

The flower hath a permanent empalement, compoſed of five ſmall oval leaves. The flower hath five petals, which are oval, or heart-ſhaped, ſpreading open; theſe are in ſome ſpecies equal, and in others, the upper two are much larger than the three lower. It hath ten ſtamina, which are alternately longer, but are ſhorter than the petals, and are terminated by oblong ſummits. In the bottom of the flower is ſituated a five-cornered germen, ſupporting an awl-ſhaped ſtyle longer than the ſtamina, which is permanent, crowned by five reflexed ſtigmas. The flower is ſucceeded by five ſeeds, each being wrapped up in the huſk of the beak, which is extended the length of the ſtyle, where they are twiſted together at the point, ſo as to form the reſemblance of a ſtork's beak.

This genus of plants is ranged in the ſecond ſection of Linnæus's ſixteenth claſs, which includes thoſe plants whoſe flowers have ten ſtamina, and the male and female organs are joined in one body. Tournefort places it in the ſixth ſection of his ſixth claſs, in which he ranges the herbs with a Roſe flower, whoſe pointal becomes a fruit with ſeveral capſules.

The SPECIES are,

1. GERANIUM (*Pratenſe*) pedunculis bifloris, foliis ſubpeltatis multipartitis pinnato laciniatis rugoſis acutis, petalis integris. Hort. Cliff. 344. *Crane's-bill with two flowers on each foot-ſtalk, target-ſhaped leaves cut into many acute ſegments, and entire petals.* Geranium batrachiodes, Gratia Dei Germanorum. C. B. P. *Crane's-bill with a Crow-foot leaf, and large blue flowers.*
2. GERANIUM (*Macrorrhizum*) pedunculis bifloris, calycibus inflatis, piſtillo longiſſimo. Hort. Cliff. 343. *Crane's-bill with two flowers on each foot-ſtalk, inflated empalements, and a very long pointal to the flower.* Geranium batrachioides, longius radicatum, odoratum. J. B. *Long-rooted ſweet-ſmelling Crane's-bill, with a Crow-foot leaf.*
3. GERANIUM (*Sanguineum*) pedunculis unifloris, foliis quinquepartitis trifidis orbiculatis. Lin. Sp. Plant. 685. *Crane's-bill with one flower on each foot-ſtalk, and orbicular leaves, which are trifid and divided into five parts.* Geranium ſanguineum, maximo flore. H. Ox. *Bloody Crane's-bill with a larger flower.*
4. GERANIUM (*Lancaſtrenſe*) pedunculis unifloris, foliis quinquepartitis laciniis obtuſis brevibus, caulibus decumbentibus. *Crane's-bill with one flower upon each foot-ſtalk, leaves divided into five parts, whoſe ſegments are ſhort, blunt, and declining ſtalks.* Geranium hæmatodes Lancaſtrenſe, flore eleganter ſtriato. Raii Hiſt. *Bloody Crane's-bill with a variegated flower.*
5. GERANIUM (*Nodoſum*) pedunculis bifloris, foliis caulinis trilobis integris ſerratis, ſummis ſubſeſſilibus. Hort. Cliff. 343. *Crane's-bill with two flowers on each foot-ſtalk, the leaves upon the ſtalks having three entire ſawed lobes, the upper leaves ſitting cloſe to the ſtalk.* Geranium 5. nodoſum. Plateau. Cluſ. Hiſt. *Knotty Crane's-bill.*
6. GERANIUM (*Phæum*) pedunculis bifloris, foliiſque alternis, calycibus ſubariſtatis, caule erecto, petalis undulatis. Lin. Sp. Plant. 681. *Crane's-bill with two flowers on each foot-ſtalk, alternate leaves, bearded empalements, an erect ſtalk, and waved petals to the flower.* Geranium phæum ſive fuſcum, petalis reflexis, folio non maculoſo. H. L. *Brown Crane's-bill with reflexed petals, and leaves not ſpotted.*
7. GERANIUM (*Fuſcum*) pedunculis bifloris, foliis quinquelobatis inciſis, petalis reflexis. *Crane's-bill with two flowers upon each foot-ſtalk, leaves divided into five lobes, which are cut, and the petals of the flowers reflexed.* Geranium phæum ſive fuſcum, petalis rectis ſeu planis, folio maculato. H. L. *Brown Crane's-bill with plain petals, and ſpotted leaves.*
8. GERANIUM (*Striatum*) pedunculis bifloris, altero breviore, foliis quinquelobis medio dilatatis, petalis bilobis venoſo reticulatis. Burm. Ger. *Crane's-bill with two flowers upon each foot-ſtalk, one bigger than the other, leaves having five lobes, and flowers with two lobes.* Geranium Romanum, verſicolor ſive ſtriatum. Park. Par. *Roman Crane's-bill with ſtriped flowers.*
9. GERANIUM (*Sylvaticum*) pedunculis bifloris, foliis ſubpeltatis quinquelobis inciſo-ſerratis, caule erecto, petalis emarginatis. Flor. Lapp. 266. *Crane's-bill with two flowers on each foot-ſtalk, target-ſhaped leaves with five lobes deeply ſawed, an erect ſtalk, and indented petals to the flower.* Geranium batrachioides montanum noſtras. Ger. *Mountain Crane's-bill with a Crow-foot leaf.*
10. GERANIUM (*Orientale*) pedunculis bifloris, foliiſque oppoſitis, petalis integris, calycibus brevioribus. *Eaſtern Dove's-foot Crane's-bill, with oppoſite leaves, two flowers on each foot-ſtalk, and a ſhort empalement.* Geranium Orientale columbinum, flore maximo, aſphodeli radice. T. Cor. *Oriental Dove's-foot Crane's-bill, with an Aſphodel root and large flowers.*
11. GERANIUM (*Perenne*) pedunculis bifloris, foliis inferioribus quinque-partito-multifidis rotundis, ſuperioribus trilobis, caule erecto. Hudſ. Flor. Ang. 265. *Crane's-bill with two flowers on each foot-ſtalk, the lower leaves having five many-pointed lobes, the upper three,*

three, and an erect ſtalk. Geranium Columbinum perenne Pyrenaicum maximum. Tourn. Inſt. R. H. 268. *Greateſt perennial Dove's-foot Crane's-bill of the Pyrennes.*

12. Geranium (*Alpinum*) pedunculis longiſſimis multifloris, calycibus ariſtatis, foliis bipinnatis. *Crane's-bill with very long foot-ſtalks ſuſtaining many flowers, bearded empalements, and double wing-pointed leaves.* Geranium Alpinum Coriandri folio, longius radicatum, flore majore purpureo. Michel. *Alpine Crane's-bill with a Coriander leaf, a long root, and a larger purple flower.*

13. Geranium (*Argenteum*) pedunculis bifloris, foliis ſubpeltatis ſeptempartitis trifidis tomentoſo-ſericeis, petalis emarginatis. Amœn. Acad. 4. p. 324. *Crane's-bill with two flowers on each foot-ſtalk, target-ſhaped leaves divided into ſeven parts, which are ſilvery, and the petals of the flower indented.* Geranium argenteum Alpinum. C. B. P. 318. *Silvery Alpine Crane's-bill.*

14. Geranium (*Maculatum*) pedunculis bifloris, caule dichotomo erecto, foliis quinquepartitis inciſis ſummis ſeſſilibus. Flor. Virg. 78. *Crane's-bill with two flowers on each foot-ſtalk, upright ſtalks divided by pairs, and cut leaves divided into five parts, the upper ſitting cloſe to the ſtalk.* Geranium batrachioides Americanum maculatum, floribus obſoletè cæruleis. Hort. Elth. 158. *American ſpotted Crane's-bill with obſolete blue flowers.*

15. Geranium (*Bohemicum*) pedunculis bifloris petalis emarginatis arillis hirtis cotyledonibus trifidis medio truncatis. Burm. Ger. 4. *Crane's-bill with two flowers on each foot-ſtalk, indented petals to the flower, hairy beards, and a trifid leaf.* Geranium annuum minus batrachiodes Bohemicum, purpuro-violaceum. Mor. Hiſt. 2. 511. *Leſſer annual Crane's-bill of Bohemia, with a purple Violet flower.*

16. Geranium (*Sibiricum*) pedunculis ſubunifloris, foliis quinquepartitis acutis foliolis pinnatifidis. Lin. Sp. Plant. 683. *Crane's-bill with one flower on a foot-ſtalk, leaves divided into five acute parts, and the ſmaller leaves wing-pointed.*

17. Geranium (*Moſchatum*) pedunculis multifloris, floribus pentandris foliis pinnatis inciſis cotyledonibus pinnatifidis. Burm. Ger. 22. *Crane's-bill with many flowers on each foot-ſtalk, having five ſtamina to the flowers, and cut winged leaves.* Geranium cicutæ folio, moſchatum. C. B. P. *Muſked Crane's-bill, frequently called Muſcovy.*

18. Geranium (*Gruinum*) pedunculis ſub multifloris, floribus pentandris, foliis ternatis lobatis. Burm. Ger. 32. *Crane's-bill with many flowers on a foot-ſtalk, five ſtamina to the flower, and ternate lobed leaves.* Geranium latifolium annuum, cæruleo flore, acu longiſſimâ. H. Ox. *Broad-leaved annual Crane's-bill with a blue flower, and a very long beak.*

19. Geranium (*Ciconium*) pedunculis multifloris, calycibus pentaphyllis, floribus pentandris, foliis pinnatis acutis ſinuatis. Lin. Sp. Plant. 680. *Crane's-bill with many flowers on each foot-ſtalk, having five-leaved empalements, five ſtamina to the flowers, and acute, ſinuated, winged leaves.* Geranium Cicutæ folio, acu longiſſimâ. C. B. P. 319. *Crane's-bill with a Hemlock leaf, and very long beaks to the ſeed.*

20. Geranium (*Viſcoſum*) pedunculis multifloris, calycibus pentaphyllis, floribus pentandris, foliis bipinnatis multifidis caule erecto. *Crane's-bill with many flowers on each foot-ſtalk, having five-leaved empalements, flowers with five ſtamina, and many-pointed winged leaves.* Geranium cicutæ folio viſcoſum erectum, acu longiſſimâ. Juſſieu. *Erect viſcous Crane's-bill with a Hemlock leaf, and very long beaks to the ſeed.*

21, Geranium (*Cucullatum*) calycibus monophyllis, foliis cuculatis dentatis. Hort. Cliff. 345. *Crane's-bill with an empalement of one leaf, and indented hooded leaves.* Geranium Africanum arboreſcens, ibiſci folio rotundo, carlinæ odore. H. L. *African-tree Crane's-bill with a round Marſhmallow leaf, and ſmell of the Carline Thiſtle.*

22. Geranium (*Anguloſum*) calycibus monophyllis, foliis cuculatis anguloſis, acutè dentatis. *Crane's-bill with a one-leaved empalement, and angular hooded leaves ſharply indented.* Geranium Africanum arboreſcens, ibiſci folio anguloſo, floribus amplis purpureis. Phil. Tranſ. 388. *African-tree Crane's-bill with an angular Marſhmallow leaf, and large purple flowers.*

23. Geranium (*Zonale*) calycibus monophyllis, foliis cordato-orbiculatis inciſis zona notatis. Hort. Upſal. 196. *Crane's-bill with a one-leaved empalement, and round heart-ſhaped leaves, which are cut, and marked with a circle.* Geranium Africanum arboreſcens, alchimillæ hirſuto folio, floribus rubicundis. Com. Præl. *African-tree Crane's-bill with an hairy Ladies Mantle leaf, and red flowers.*

24. Geranium (*Inquinans*) calycibus monophyllis, foliis orbiculato-reniformibus tomentoſis crenatis integriuſculis, caule fruticoſo. Hort. Upſal. 195. *Crane's-bill with a one-leaved empalement, and round kidney-ſhaped leaves which are woolly, crenated, entire, and a ſhrubby ſtalk.* Geranium Africanum arboreſcens, malvæ folio plano lucido, flore elegantiſſimè kermeſino. Di van Leur. Boerh. Ind. *African-tree Crane's-bill, with a plain, ſhining, Mallow leaf, and an elegant ſcarlet flower.*

25. Geranium (*Capitatum*) calycibus monophyllis, foliis lobatis undatis villoſis, caule fruticoſo. Hort. Upſal. 196. *Crane's bill with empalements of one leaf, leaves divided into lobes, which are waved and hairy, and a ſhrubby ſtalk.* Geranium Africanum friteſcens, malvæ folio odorato laciniato. H. L. *African ſhrubby Crane's-bill with a jagged, ſweet-ſmelling, Mallow leaf.*

26. Geranium (*Vitifolium*) calycibus monophyllis, foliis adſcendentibus lobatis pubeſcentibus, caule fruticoſo. Hort. Upſal. 196. *Crane's-bill with one-leaved empalements, aſcending leaves which have lobes, are covered with ſoft hairs, and a ſhrubby ſtalk.* Geranium Africanum fruteſcens, malvæ folio laciniato, odorato inſtar meliſſæ, flore purpuraſcente. Boerh. Ind. *African ſhrubby Crane's-bill, with a jagged Mallow leaf ſmelling like Balm, and a purpliſh coloured flower.*

27. Geranium (*Papileonaceum*) calycibus monophyllus, corollis papilionaceis, alis carinaque minutis, foliis angulatis, caule fruticoſo. Hort. Cliff. 345. *Crane's-bill with an empalement of one leaf, a butterfly flower, whoſe wings and keel are very ſmall, and a ſhrubby ſtalk.* Geranium Africanum arboreſcens, malvæ folio mucronato, petalis florum inferioribus vix conſpicuis. Phil. Tranſ. *African-tree Crane's-bill with a pointed Mallow leaf, and the under petals of the flower ſcarce diſcernible.*

28. Geranium (*Acetoſum*) calycibus monophyllis, foliis glabris obovatis carnoſis crenatis, caule fruticoſo. Hort. Cliff. 345. *Crane's-bill with empalements of one leaf, ſmooth, oval, fleſhy leaves, which are crenated, and a ſhrubby ſtalk.* Geranium Africanum fruteſcens, folio craſſo & glauco, acetoſæ ſapore. Com. Præl. *African ſhrubby Crane's-bill with a thick glacuous leaf, and an acid taſte like Sorrel.*

29. Geranium (*Carnoſum*) calycibus monophyllis, caule fruticoſo, articulis carnoſo gibboſis, foliis pinnatifidis laciniatis, petalis linearibus. Lin. Sp. Plant. 67. *Crane's-bill with an empalement of one leaf, a ſhrubby ſtalk with fleſhy knees, wing-pointed leaves, and very narrow petals to the flower.* Geranium Africanum fruteſcens, chelidonii folio, petalis florum anguſtis albidis, carnoſo caudice. Phil. Tranſ. Geranium Africanum, folio alceæ, flore albo. Boerh. Ind. alt. *African ſhrubby Crane's-bill with a leaf like the Alcea, the petals of the flower white and narrow, and a fleſhy ſtalk.*

30. Geranium (*Gibboſum*) calycibus monophyllis, caule fruticoſo, geniculis carnoſis gibboſis, foliis ſubpinnatis appoſitis. Lin. Sp. Plant. 677. *Crane's-bill with a one-leaved empalement, ſhrubby ſtalk with fleſhy knees, and winged leaves placed oppoſite.* Geranium Africanum noctu olens, tuberoſum & nodoſum, aquilegiæ foliis. H. L. *African Crane's-bill ſmelling ſweet in the night, with knotty tuberous ſtalks, and leaves like Columbine.*

31. Geranium (*Fulgidum*) calycibus monophyllis, foliis tripartitis inciſis, intermedia majore umbellis, geminis, caule fruticoſo carnoſa. Lin. Vir. 67. *Crane's-bill*

bill with one-leaved empalements, leaves cut into three ſegments, the middle one being the largeſt, double foot-ſtalks with flowers growing in umbels, and a ſhrubby fleſhy ſtalk. Geranium Africanum, folio alceæ, flore coccineo fulgidiſſimo. Boerh. Ind. alt. 1. p. 264. *African Crane's-bill with a Vervain Mallow leaf, and a deep ſcarlet flower.*

32. Geranium (*Peltatum*) calycibus monophyllis, folis, quinquelobis integerrimis glabris peltatis, caule fruticoſo. Hort. Cliff. 345. *Crane's-bill with empalements of one leaf, and ſmooth target-ſhaped leaves, having five lobes, which are entire.* Geranium Africanum foliis inferioribus aſari, ſuperioribus ſtaphidiſagriæ, maculatis, ſplendentibus, & acetoſæ ſapore. Com. Præl. *African Crane's-bill with the under leaves like Aſarabacca, and the upper leaves like Staveſacre, ſhining, ſpotted, and taſting like Sorrel.*

33. Geranium (*Alchimilloides*) calycibus monophyllis, foliis orbiculatis palmatis inciſis piloſis, caule herbaceo. Lin. Vir. 67. *Crane's-bill with empalements of one leaf, roundiſh hand-ſhaped leaves, which are divided, hairy, and an herbaceous ſtalk.* Geranium Africanum, alchimillæ hirſuto folio, floribus albidis. H. L. *African Crane's-bill with a hairy Ladies Mantle leaf, and whitiſh flowers.*

34. Geranium (*Odoratiſſimum*) calycibus monophyllis, caule carnoſo breviſſimo, ramis herbaceis longis foliis cordatis. Hort. Cliff. 345. *Crane's-bill with empalements of one leaf, a very ſhort fleſhy ſtalk, long herbaceous branches, and heart-ſhaped leaves.* Geranium Africanum, folio malvæ craſſo molli odoratiſſimo, floſculo pentapetalo albo. Boerh. Ind. alt. *African Crane's-bill with a thick, ſoft, ſweet-ſmelling Mallow leaf, and a ſmall white flower compoſed of five leaves.*

35. Geranium (*Triſte*) calycibus monophyllis, ſeſſilibus ſcapis bifidis monophyllis. Lin. Sp. 950. *Crane's-bill with ſeſſile empalements of one leaf, a bifid ſtalk, and a roundiſh root.* Geranium Americanum, noctu olens, radice tuberoſâ, triſte. Corn. H. Ox. *American tuberous-rooted Crane's-bill, ſmelling ſweet in the night.*

36. Geranium (*Myrrhifolium*) calycibus monophyllis, foliis bipinnatis, inferioribus cordatis lobatis, caule herbaceo, calycibus ſtrigoſis. Burm. Ger. 59. *Crane's-bill with empalements of one leaf, doubly wing-pointed leaves, the lower heart-ſhaped with lobes, and an herbaceous ſtalk.* Geranium Africanum tuberoſum, anemones folio, incarnato flore. Par. Bat. *Tuberous-rooted African Crane's-bill with an Anemony leaf, and a pale, fleſh-coloured flower.*

37. Geranium (*Paſtinacæfolium*) calycibus monophyllis, foliis decompoſitis pinnatifidis, acutis pedunculis longiſſimis. *Crane's-bill with empalements of one leaf, decompounded leaves ending in acute winged points, and very long foot-ſtalks to the flower.* Geranium Africanum noctu olens, radice tuberoſâ, foliis paſtinacæ incanis lanuginoſis latioribus, flore pallide flaveſcente. H. L. B. *Night-ſmelling Crane's-bill with a tuberous root, broad, woolly, hoary, Parſnep leaves, and a pale yellowiſh flower.*

38. Geranium (*Villoſum*) calycibus monophyllis, foliis pinnatifidis villoſis, laciniis linearibus. *Crane's-bill with empalements of one leaf, hairy wing-pointed leaves, having very narrow ſegments.* Geranium Æthiopicum, noctu olens, radice tuberoſâ, foliis myrrhidus anguſtioribus. Breyn. Cent. *Night ſweet-ſmelling Ethiopian Crane's-bill with a tuberous root, and narrow Cicely leaves.*

39. Geranium (*Lobatum*) calycibus monophyllis, caule truncato, ſcapis ſubradicalibus, umbella compoſita. Lin. Sp. 950. *Crane's-bill with empalements of one leaf, a truncated ſtalk, foot-ſtalks ariſing from the root, and a compound umbel of flowers.* Geranium Africanum noctu olens, folio vitis hirſuto, tuberoſum. H. L. *Night ſweet-ſmelling African Crane's-bill with a hairy Vine leaf, and a tuberous root.*

40. Geranium (*Coriandrifolium*) calycibus monophyllis, foliis bipinnatis linearibus ſquarroſis, caule herbaceo læviuſculo. Lin. Sp. 949. *Crane's-bill with a one-leaved empalement, doubly winged rough leaves, and a very ſmooth ſtalk.* Geranium Africanum, folio coriandri, floribus incarnatis, minus. H. L. *Leſſer African Crane's-bill with a Coriander leaf, and a fleſh-coloured flower.*

41. Geranium (*Romanum*) pedunculis multifloris, floribus pentandris, foliis pinnatis inciſis, ſcapis radicalibus. Burm. Ger. 30. *Crane's-bill with many flowers on each foot-ſtalk, cut winged leaves, and foot-ſtalks riſing from the root.* Geranium myrrhinum tenuifolium, amplo flore purpureo. Barrel. rar. 563.

42. Geranium (*Groſſularoides*) calycibus monophyllis, foliis cordatis ſubrotundis lobatis crenatis, caule herbaceo lævi. Burm. Ger. 53. *Crane's-bill with empalements of one leaf, roundiſh heart-ſhaped leaves which are crenated, and herbaceous ſmooth ſtalks.* Geranium Africanum, uvæ criſpæ folio, floribus exiguis rubellis. H. L. *African Crane's-bill with a Gooſeberry leaf, and ſmall reddiſh flowers.*

43. Geranium (*Betulinum*) calycibus monophyllis, foliis ovatis inæqualiter ſerratis planis, caule fruticoſo. Lin. Sp. Plant. 679. *Crane's-bill with one-leaved empalements, and oval plain leaves unequally ſawed, and a ſhrubby ſtalk.* Geranium fruteſcens, folio lato dentato, flore magno rubente. Burm. Afr. 92. tab. 33. *Shrubby Crane's-bill with a broad indented leaf, and large reddiſh flower.*

44. Geranium (*Chium*) pedunculis multifloris, floribus pentandris, foliis cordatis inciſis, ſuperioribus lyratopinnatifidis. Burm. Ger. 35. *Crane's-bill with many flowers on each foot-ſtalk, heart-ſhaped cut leaves at bottom, the upper lyre-ſhaped and winged.* Geranium chium vernum Caryphyllatæ folio. Tourn. Cor. 20.

45. Geranium (*Malacoides*) pedunculis multifloris, floribus pentandris foliis cordatis ſublobatis. Hort. Cliff. 344. *Crane's-bill with many flowers on each ſtalk, and heart-ſhaped lobed leaves.* Geranium folio Althææ. C. B. P. 318.

46. Geranium (*Glaucophyllum*) pedunculis multifloris, floribus pentandris, foliis ovatis ſerratis incanis linearis. Lin. Sp. 952. *Crane's-bill with many flowers on each ſtalk, and oval ſawed leaves.* Geranium Ægyptiacum glaucophyllon, roſtris longiſſimis plumoſis.

47. Geraniun (*Carolinianum*) pedunculis bifloris, calycibus ariſtatis, foliis multifidis, arillis hirſutis. Prod. Leyd. 351. *Crane's-bill with two flowers on each ſtalk, bearded empalements, many pointed leaves, and hairy beaks.* Geranium columbinum Carolinum, capſulis nigris hirſutis. Hort. Elth. 162.

48. Geranium (*Althæoides*) calycibus monophyllis, foliis cordato-ovatis plicatis ſinuatis crenatis, caule herbaceo proſtrato. Hort. Cliff. 354. *Crane's-bill with a one-leaved empalement, oval heart-ſhaped plaited leaves, which are indented, and a proſtrate herbaceous ſtalk.* Geranium folio Althææ. Africanum odore meliſſæ. Boerh. Ind. 1. p. 263.

The firſt ſort grows naturally in moiſt meadows in many parts of England, but is frequently planted in gardens for the beauty of its large blue flowers; of this there is a variety with white flowers, and another with variegated flowers; but theſe are apt to degenerate to the common ſort, if they are raiſed from ſeeds, but by parting of their roots they may be continued. It hath a perennial root, which ſends up many ſtalks, which riſe near three feet high, garniſhed with target-ſhaped leaves, divided into ſix or ſeven lobes; theſe are cut into ſeveral acute ſegments, after the manner of winged leaves, ending in many points. The flowers are produced at the top of the ſtalks, each foot-ſtalk ſuſtaining two flowers, whoſe petals are large and equal; they are of a fine blue colour, and appear in May and June.

The varieties of this may be preſerved by parting of their roots in autumn; they may be planted in almoſt any ſoil or ſituation, and require no other culture but to keep them clean from weeds. They may alſo be propagated by ſeeds, but by this method they are very apt to vary in the colour of their flowers. If the ſeeds of theſe plants are permitted to ſcatter, the plants will come up without any farther care.

The ſecond ſort grows naturally in Germany and Switzerland; this hath a thick, fleſhy, perennial root, from which ariſe ſeveral branching ſtalks, which grow about one foot high, garniſhed with leaves at each joint, which are divided into five lobes; and are divided at the top into many ſhort ſegments, which are crenated on their edges; they are of a light green, and ſmooth. The flowers are produced at the end of the branches, many growing together in a bunch, but each ſhort foot-ſtalk ſuſtains two flowers. The flowers have ſwollen empalements, reſembling inflated bladders. The petals are pretty large, equal, and of a fine bright purple colour, and the ſtamina and ſtyle are much longer than the petals; the whole plant, when rubbed, emits an agreeable odour. This flowers about the ſame time with the firſt ſort, and may be propagated and treated in the ſame manner, the plant being equally hardy.

The third ſort grows naturally in many parts of England, but is often admitted into gardens; this hath pretty thick, fleſhy, fibrous roots, which grow to a large head, from which ariſe many ſtalks, garniſhed with leaves, divided into five lobes, which are again divided almoſt to the midrib. The flowers ſtand upon long hairy foot-ſtalks, which come out from the ſide of the ſtalk, each ſuſtaining one flower, compoſed of five broad regular petals, which are of a deep purple colour. This ſort flowers in June and July; there are two varieties mentioned of this ſort as diſtinct ſpecies, one whoſe ſtalks grow more erect, and the other hath leaves more deeply divided; but the plants which I have raiſed from ſeeds of theſe do not come up the ſame as the parent plants, ſo they are only ſeminal varieties.

This hath a perennial root, which may be parted in autumn, and thereby propagated; or it may be propagated by ſeeds, and the plants treated in the ſame manner as the firſt.

The fourth ſort hath been ſuppoſed by ſome to be only a variety of the third, but it is undoubtedly a diſtinct ſpecies; for I have frequently raiſed the plants from ſeeds, which have always proved to be the ſame. The ſtalks of this plant are ſhorter than thoſe of the third, and ſpread flat on the ground; the leaves are much leſs, and not ſo deeply divided, and the flowers much ſmaller and of a pale colour, marked with purple; it grows naturally in Lancaſhire and Weſtmoreland, where I ſaw it in plenty. This may be propagated and treated in the ſame manner as the others.

The fifth ſort is a perennial plant, of ſmaller growth than either of the former. It riſes with branching ſtalks about ſix inches high, garniſhed with leaves, having three pretty broad lobes, which are undivided, and crenated on their edges: thoſe on the lower part of the ſtalks are placed oppoſite, upon pretty long foot-ſtalks, but the upper leaves ſit cloſe to the ſtalks and are ſingle. The flowers are produced at the end of the ſtalks, ſtanding together upon two ſhort foot-ſtalks; they are of a dirty purple colour, and appear in June. It grows naturally in France. This ſort may be propagated and treated in the ſame manner as the firſt.

The ſixth ſort grows naturally on the Alps and Helvetian mountains, and is found in ſome places in the North of England: this hath a perennial root, from which ariſe ſeveral ſtalks near a foot high, with leaves which are divided into five or ſix lobes, which are laciniated on their edges; thoſe which grow near the root have long foot-ſtalks, but thoſe on the upper part of the ſtalk ſit cloſe; the ſtalk branches out at the top into three or four diviſions, each being terminated by two or three foot-ſtalks, ſuſtaining two flowers of a dark purple colour, with erect petals. This flowers in June, and may be propagated by ſeeds or parting of the roots, in the ſame manner as the firſt ſort.

The ſeventh ſort is very like the ſixth, but the leaves are larger, the lobes ſhorter, broader, and not ſo much cut; they are ſtriped with black; the ſtalks riſe higher, the flowers are larger, and the petals are reflexed. Theſe differences are permanent, ſo are ſufficient to conſtitute a ſpecific difference between them. This may be propagated and treated in the ſame manner as the firſt ſort. It grows naturally on the Alps.

The eighth ſort hath a perennial root, which ſends up many branching ſtalks a foot and a half high, garniſhed with light green leaves; thoſe on the lower part of the ſtalk hath five lobes, and ſtand upon long foot-ſtalks; but thoſe on the upper part have but three lobes, ſit cloſer to the ſtalks, and are ſharply indented on the edges; the flowers ſtand upon long ſlender foot-ſtalks, each ſuſtaining two flowers, compoſed of five obtuſe petals, which are deeply indented at the top; they are of a dull white, with many purple ſtripes running longitudnally thro' them. Theſe appear in June, and in cool ſeaſons there will be a ſucceſſion of flowers a great part of July. This ſort is very hardy, ſo may be propagated by dividing of the roots, or from ſeeds, in the ſame manner as the firſt ſort.

The ninth ſort grows plentifully in the meadows in Lancaſhire and Weſtmoreland; this hath a perennial root, which ſends out three or four upright ſtalks about nine inches high, garniſhed with leaves, having five lobes, which are ſawed on their edges; they are placed oppoſite on the ſtalks; thoſe on the lower part have pretty long foot-ſtalks, but thoſe on the upper part ſit cloſer. The flowers are ſituated on the top of the ſtalks, ſtanding upon ſhort foot-ſtalks, each ſuſtaining two pretty large blue flowers, with entire petals. This flowers in May and June, and may be propagated and treated in the ſame way as the firſt ſort.

The tenth ſort was diſcovered by Dr. Tournefort in the Levant, from whence he ſent the ſeeds to the Royal Garden at Paris; this hath a perennial root, from which ariſe a few weak ſtalks about nine inches long, garniſhed with leaves which are round, and divided into five lobes, which are indented at the top, and placed oppoſite on the ſtalks. The flowers ſtand upon pretty long foot-ſtalks, which come ſingle from the joints of the ſtalks, each ſuſtaining two purpliſh flowers with entire petals, having very ſhort empalements. It flowers in June, and may be propagated either from ſeeds, or by parting of the roots in the ſame manner as the firſt ſort, but the plants require a drier ſoil and a warmer ſituation; for although in common winters it will live in the open air, yet in ſevere froſt theſe plants are ſometimes killed, eſpecially when they are planted in moiſt cold land.

The eleventh ſort grows naturally on the Pyrenean mountains; this hath a perennial root, from which ariſe many branching ſtalks a foot and a half high, garniſhed with round leaves, divided into many obtuſe ſegments at the top, placed oppoſite. The flowers are produced upon ſhort foot-ſtalks, which come out at the diviſions on the ſides, and at the top of the ſtalks; they are in ſome of a pale purple colour, and in others white. The petals of the flowers are bifid, like thoſe of the common Dove's-foot Crane's-bill, to which the whole plant bears ſome reſemblance; but the ſtalks are erect, the leaves and flowers much larger, and the root is perennial; this will propagate itſelf faſt enough by its ſcattered ſeeds where it has once got poſſeſſion, and will thrive in any ſoil or ſituation.

The twelfth ſort grows naturally upon the Alps. The ſeeds of this were ſent me by Sig. Micheli, of Florence; this hath a perennial root, which runs very deep into the ground. The lower leaves of the plant have very long foot-ſtalks, they are doubly winged and ſmooth. The ſtalks riſe a foot and a half high, which are garniſhed with leaves of the ſame form as the lower, but ſmaller, and ſtand oppoſite. The flowers grow many together upon very long foot-ſtalks; they are purple. This flowers in June, but has never ripened any ſeeds in England. The plant is hardy, and lives in the open air, but as the root puts out no offſets, nor perfects ſeeds here, we have not been able to propagate it.

The thirteenth ſort grows naturally on the Alps; this hath a very thick perennial root, from which come out roundiſh leaves, divided into many parts, ſtanding upon pretty long foot-ſtalks; they are very ſilvery, and ſhining like ſilk. The flower-ſtalks riſe about four or five inches high, garniſhed with one or two ſmall leaves like thoſe below, which ſit cloſe to the ſtalk. The ſtalks are terminated by two pretty large pale flowers, whoſe petals are entire, and ſpread open flat. It flowers in June, but rarely ripens ſeeds here; it may be propagated by parting of the roots in the ſame manner as the firſt, and muſt have a ſhady ſituation.

The fourteenth ſort grows naturally in North America, from whence the ſeeds were ſent to England; this hath a perennial root, from which ariſe ſeveral ſtalks about one foot high, which divide by pairs, and from the middle of the diviſions come out the foot-ſtalks of the flowers, which are pretty long and naked, each ſuſtaining two pale purple flowers with entire petals. The leaves are divided into five parts, which are cut on their edges, and are placed oppoſite, the lower having pretty long foot-ſtalks, but the upper ſit cloſe to the ſtalks. It flowers in June, and frequently ripens ſeeds, from which the plant may be propagated; it thrives very well in the open air, and requires no other culture but to keep it clean from weeds.

The fifteenth ſort grows naturally in Bohemia; this is an annual plant, which ſends out many ſtalks, dividing into ſeveral ſmaller, which are garniſhed with leaves divided into five lobes, crenated on their edges; they ſtand upon long foot-ſtalks, and are for the moſt part oppoſite. The flowers ſtand by pairs upon pretty long ſlender foot-ſtalks, which come out from the ſide of the ſtalk; they are of a fine blue colour, and are ſucceeded by ſeeds, whoſe capſules and beaks are black. It flowers moſt part of ſummer, and the ſeeds ripen ſoon after, which, if permitted to ſcatter, there will be a ſupply of plants, which want no other care but to keep them clean from weeds.

The ſixteenth ſort grows naturally in Siberia. The ſeeds of this plant were ſent me by Sir Charles Linnæus, profeſſor of botany at Upſal; this ſort hath a perennial root. The leaves are divided into five acute lobes, which are cut into many ſharp wing-like ſegments on their edges; they are placed oppoſite, and have long ſlender foot-ſtalks. The foot-ſtalks of the flower come out from the wings of the ſtalk; they are pretty long, ſlender, and each ſuſtain one pale purpliſh flower. This ſort flowers in June, and perfects its ſeeds very well, ſo may be eaſily propagated; it will grow on any ſoil, or in any ſituation.

The ſeventeenth ſort is an annual plant, which is ſometimes found growing naturally in England, but is frequently preſerved in gardens for the muſky odour of the leaves, which in dry weather is very ſtrong. The leaves of this are irregularly winged, the lobes grow alternate, and are cut into many obtuſe ſegments on their edges. The ſtalks branch into many diviſions, and frequently decline to the ground. The flowers are produced in umbels upon long foot-ſtalks, which ariſe from the wings of the ſtalks; they are ſmall, blue, and have but five ſtamina in each, their empalements are compoſed of five leaves. It flowers in May, June, and July, and the ſeeds ripen ſoon after; which, if permitted to ſcatter, there will be a ſupply of plants without care, which will require no other culture but to keep them clean from weeds, and thin them where they are too cloſe; it will thrive on any ſoil, or in any ſituation.

The eighteenth ſort grows naturally in Crete; this is an annual plant with very broad leaves, which are cut on their ſides regularly, in form of winged leaves, and are crenated on their borders. The flowers are produced on pretty long foot-ſtalks, which come out from the wings of the ſtalk; they have five-leaved empalements, and are compoſed of five entire blue petals; theſe are ſucceeded by the largeſt and longeſt beaks of any ſpecies of this genus yet known. It flowers in June and July; this ripens ſeeds very well, and if they are permitted to ſcatter, the plants will come up without care; or they may be ſown in the ſpring where they are deſigned to remain, and will require no other culture but to thin them where they are too cloſe, and keep them clean from weeds.

The nineteenth ſort grows naturally in Germany and Italy; this is an annual plant, which hath ſeveral proſtrate ſtalks near a foot long, garniſhed with winged leaves, cut into ſeveral acute parts, placed oppoſite. The flowers come out from the wings of the ſtalk, upon foot-ſtalks about three inches long; ſome of theſe ſuſtain many flowers, but others have no more than two; they are of a pale blue colour, and are ſucceeded by very long beaks, but not ſo long or large as thoſe of the former ſort; but the ſeeds of this are frequently uſed for hygrometers, to ſhew the moiſture of the air: if the ſeeds of this are permitted to ſcatter, the plants will come up and thrive without any other care than to keep them clear from weeds, and the plants which come up in autumn will flower early in May, but thoſe which are ſown in the ſpring ſeldom flower till July. Dr. Linnæus ſuppoſes this and the former ſort to be the ſame, but whoever has ſeen the two plants, cannot doubt of their being diſtinct ſpecies.

The ſeeds of the twentieth ſort were ſent to the Chelſea garden by Dr. Juſſieu, profeſſor of botany at Paris; this is an annual plant, which hath upright ſtalks near two feet high, which are garniſhed with double winged leaves, ending in many points; theſe are very viſcous, and ſtand oppoſite. The flowers are produced on long naked foot-ſtalks, ſtanding many together upon each; they are of a pale blue colour, and have but five ſtamina; their empalements are compoſed of five leaves, which end with awns. It flowers in May, June, and July, according to the times when the ſeeds are ſown, and the ſeeds ripen a month after; this requires no other culture than the two former ſorts.

There are ſeveral other ſorts of annual Geraniums, ſome of which grow naturally in England, and are troubleſome weeds in a garden, others grow naturally in France, Spain, Italy, and Germany, and are preſerved in botanic gardens for the ſake of variety; but as they are plants of little beauty, they are rarely admitted into other gardens, therefore I ſhall not trouble the reader with an enumeration of the ſpecies, which would ſwell this article too much; ſo I ſhall next treat of the African Crane's-bills, which are preſerved in moſt of the curious gardens, where there is conveniency to ſcreen them from the froſt in winter.

The twenty-firſt ſort grows naturally near the Cape of Good Hope; this riſes with a ſhrubby ſtalk eight or ten feet high, ſending out ſeveral irregular branches, garniſhed with roundiſh leaves, whoſe ſides are erect, ſo form a ſort of hood by the hollow cavity made in the leaf. The baſe of the leaves are cut in form of a heart-ſhaped leaf, and from the foot-ſtalk run many nerves ariſing from a point, but diverge toward the ſides; the borders of the leaves are ſharply indented, thoſe on the lower part of the branches have long foot-ſtalks, and are placed without order on every ſide, but thoſe on the upper part have ſhorter foot-ſtalks, and ſtand oppoſite. The flowers are produced in large panicles on the top of the branches; their empalements are of one leaf, deeply cut into five ſegments, and cloſely covered with ſoft hairs. The petals are large, entire, and of a purple blue colour. It flowers in June, July, Auguſt, and September, and the flowers are ſucceeded by ſeeds, having ſhort hairy beaks.

The twenty-ſecond ſort has ſome appearance of the twenty-firſt, but the leaves are of a thicker ſubſtance, divided into many acute angles, having purple edges, which are acutely indented. The ſtalks and leaves are very hairy. The branches are not ſo irregular as thoſe of the former, nor are the bunches of flowers near ſo large; theſe differences are permanent in the plants which are raiſed from ſeeds, ſo it is undoubtedly a diſtinct ſpecies, though Dr. Linnæus ſuppoſes them to be the ſame.

The twenty-third ſort comes from the Cape of Good Hope, but is one of the oldeſt, and the moſt common ſort in the Engliſh gardens; this riſes with a ſhrubby ſtalk four or five feet high, and divides into a great number of irregular branches, ſo as to form a large head, which is often eight or ten feet high. The branches are garniſhed with roundiſh heart-ſhaped leaves, indented on their edges in ſeveral obtuſe ſegments, which are cut into ſhort teeth at their brims; theſe have a purpliſh circle, or mark, like a horſe-ſhoe, through the leaf, going from one ſide of the baſe to the other, correſponding with the border of the leaf; theſe leaves when gently rubbed, have a ſcent like ſcalded Apples. The flowers are produced in pretty cloſe bunches, ſtanding upon foot-ſtalks about five or ſix inches in length, which come out from the wings of the ſtalk, toward the end of the branches; they are of a reddiſh purple colour, and continue in ſucceſſion great part of ſummer; there is a variety of this with fine variegated leaves, which is preſerved in moſt of the Engliſh gardens for the beauty of its leaves; but as this accidentally came from the other, it is not a diſtinct ſpecies, therefore I have not enumerated it.

The twenty-fourth ſort grows naturally at the Cape of Good Hope; this riſes with a ſoft ſhrubby ſtem to the height of eight or ten feet, ſending out ſeveral branches, which are generally erect; theſe are garniſhed with roundiſh kidney-ſhaped leaves, which are of a thick ſubſtance, and of a lucid green, ſtanding on pretty long foot-ſtalks; they are covered with ſoft hairs on their under ſide, and are placed without any order. The flowers grow in looſe bunches upon long ſtiff foot-ſtalks, which come out from the wings of the ſtalk; they are of a bright ſcarlet colour, ſo make a fine appearance, and there is a ſucceſſion of theſe flowers during all the ſummer months.

The twenty-fifth ſort grows naturally at the Cape of Good Hope, but has been many years an inhabitant of the Engliſh gardens; this riſes with a ſhrubby ſtalk four or five feet high, dividing into ſeveral weak irregular branches, garniſhed with leaves divided into three unequal lobes, which are hairy and waved on their edges; they are placed alternate on the branches, and ſtand upon hairy foot-ſtalks. The flowers grow in cloſe roundiſh heads on the top of the foot-ſtalks, forming a ſort of corymbus; they are of a purpliſh blue colour, and continue in ſucceſſion great part of the ſummer. The leaves of this ſort, when rubbed, have an odour like dried Roſes, from whence many have given it the title of Roſe Geranium.

The twenty-ſixth ſort is a native of the Cape of Good Hope; this riſes with an upright ſhrubby ſtalk to the height of ſeven or eight feet, ſending out many pretty ſtrong branches, garniſhed with leaves ſhaped ſomewhat like thoſe of the Vine; thoſe on the lower part ſtand upon long foot-ſtalks, but the upper have ſhort ones; when the leaves of this are rubbed, they have a ſcent of Balm. The flowers grow in compact cluſters on the top of long naked foot-ſtalks, which come out from the wings of the ſtalk, but riſe much higher than the branches; they are ſmall, and of a pale blue colour, ſo make no great figure, but there is a ſucceſſion of them moſt part of the ſummer.

The twenty-ſeventh ſort riſes with an upright ſhrubby ſtalk ſeven or eight feet high, ſending out ſeveral ſide branches, garniſhed with large, angular, rough leaves, ſtanding upon long foot-ſtalks. The flowers are produced in large panicles at the end of the branches; theſe are ſhaped ſomewhat like a Butterfly-flower, the two upper petals, which are pretty large, turn upward like a ſtandard in the leguminous flowers; theſe are finely variegated, but the three under petals are ſo ſmall, as not to appear at a ſmall diſtance; theſe are reflexed downward, ſo are ſcreened from ſight, unleſs the flowers are viewed near. This ſort flowers in May, at which time the plants make a fine appearance, but they are not ſucceeded by any more afterward, as moſt of the other ſorts are; this grows naturally at the Cape of Good Hope.

The twenty-eighth ſort is from the ſame country; this riſes with a ſhrubby ſtalk ſix or ſeven feet high, ſending out ſeveral ſide branches, garniſhed with oblong, oval, fleſhy, ſmooth leaves, of a gray colour, which are crenated on their edges, and have an acid taſte like Sorrel. The flowers ſtand upon pretty long foot-ſtalks, which ariſe from the wings of the ſtalks, each ſuſtaining three or four flowers, whoſe petals are narrow and unequal in ſize; they are of a pale bluſh colour, with ſome ſtripes of a light red; theſe continue in ſucceſſion moſt part of the ſummer. There is a variety of this with ſcarlet flowers, which is ſaid to have been raiſed from the ſeeds of this ſort. The leaves of it are larger, and ſeem to be an intermediate ſpecies between this and the twenty-fourth ſort, for the flowers are larger than thoſe of the twenty-eighth ſort, and are of a pale ſcarlet colour.

The twenty-ninth ſort hath a thick, fleſhy, knotted ſtalk, which riſes about two feet high, ſending out a few ſlender fleſhy branches, garniſhed thinly with double winged leaves, which, on the lower part of the ſtalk, ſtand upon foot-ſtalks, but thoſe above ſit cloſe to the branches. The flowers are produced in ſmall cluſters at the end of the branches; theſe have five narrow white petals, which make no appearance, and continue in ſucceſſion moſt part of the ſummer. It grows naturally at the Cape of Good Hope.

The thirtieth ſort hath a round fleſhy ſtalk with ſwelling knots at the joints, which riſe about three feet high, and ſend out ſeveral irregular branches, which are ſmooth; they are thinly garniſhed with ſmooth, fleſhy, winged leaves, ending in obtuſe points; they are of a gray colour, and ſtand upon ſhort foot-ſtalks. The flowers ſtand four or five upon each foot-ſtalk, which ariſes from the wings of the ſtalk, and are of a dark purple colour. The petals are broader than thoſe of the former ſort, and have a very agreeable ſcent in the evening, after the ſun has left them ſome time; this and the former ſort are ſuppoſed to be one ſpecies by Dr. Linnæus, but they are very different in many particulars, which are permanent in the plants which come up from ſeeds.

The thirty-firſt ſort hath a fleſhy ſtalk which ſeldom riſes a foot high, and puts out very few branches; theſe are garniſhed with ſmooth, light, green leaves, divided into three lobes, the middle ſegment being much larger than the others. The flowers ſtand upon ſhort foot-ſtalks, each ſuſtaining two or three flowers on the top, which are of a very deep ſcarlet colour, and have unequal petals; this ſort is not regular in its ſeaſon of flowering, ſometimes it is in ſpring, at other times in ſummer, and frequently in autumn. The leaves of this ſort fall off, ſo that the ſtalks are frequently deſtitute of them for three or four months in ſummer, and appear as if they were dead, but in autumn they put out freſh leaves again.

The thirty-ſecond ſort hath many weak ſhrubby ſtalks, which require ſupport to prevent their falling on the ground; theſe extend to the length of two or three feet, and are garniſhed with fleſhy leaves, divided into five obtuſe lobes, which are entire; theſe have ſlender foot-ſtalks, which are faſtened to the middle of the leaf like the handle of a target. The leaves are ſmooth, of a lucid green, and have a circular purple mark in their middle; they have an acid flavour, and are placed alternate on their branches. The flowers are produced upon pretty long foot-ſtalks, which come out from the wings of the ſtalk, each foot-ſtalk ſuſtaining four or five purple flowers, compoſed of five unequal petals. This ſort continues a ſucceſſion of flowers moſt of the ſummer months, and frequently ripen ſeeds here.

The thirty-third ſort ſends out ſeveral herbaceous ſtalks about a foot and a half in length; which trail upon the ground if they are not ſupported; theſe are garniſhed with roundiſh hand-ſhaped leaves, which are cut into many parts, and are very hairy. The flowers are of a pale bluſh colour, and ſtand ſeveral together upon very long foot-ſtalks; there is a ſucceſſion of theſe during all the ſummer months, and the ſeeds ripen accordingly about a month after the flowers are fallen: there is a variety of this ſort which has a dark circle in the middle of the leaves, which is mentioned as a diſtinct ſpecies, but I find it is apt to vary from ſeeds.

The thirty-fourth ſort hath a very ſhort fleſhy ſtalk, which divides near the ground into ſeveral heads, each having many leaves, which ariſe on ſeparate foot-ſtalks from the heads; theſe are heart-ſhaped, ſoft, and downy, and have a ſtrong ſcent like Aniſeed; from theſe heads come out ſeveral ſlender ſtalks near a foot in length, which lie proſtrate on the ground, and are garniſhed with rounder leaves than thoſe near the root, but are of the ſame texture, and have the like odour. The flowers are produced from the ſide of theſe ſtalks, three, four, or five ſtanding together upon ſlender foot-ſtalks; they are very ſmall and white, ſo make little appearance, but the plant is preſerved in gardens for the ſcent of its leaves.

The thirty-fifth ſort hath a thick, roundiſh, tuberous root, from which ariſe ſeveral hairy leaves, which are finely divided, almoſt like thoſe of the Garden Carrot; theſe ſpread near the ground, and between theſe come out the ſtalks, which riſe about a foot high, which are garniſhed with two or three leaves of the ſame ſort with thoſe below, but are ſmaller, and ſit cloſer to the ſtalks; from theſe ariſe two or three naked foot-ſtalks, which are terminated by a bunch of yellowiſh flowers, marked with dark purple ſpots, which ſmell very ſweet after the ſun hath left them; theſe are frequently ſucceeded by ſeeds, which ripen in autumn. This is the ſort which has been long cultivated in the gardens, and is known by the title of Geranium noctu olens, *or Night-ſcented Crane's-bill.*

The thirty-ſixth ſort hath a knobbed tuberous root like the laſt, from which come out ſeveral pretty large leaves, compoſed of many lobes, ſet along the mid-rib in the form of a winged leaf; theſe are narrow at their baſe, but are very much enlarged at their ends, which are rounded, and cut all along their ſide and top into many acute points; the ſtalks which ſuſtain the flowers ariſe immediately from the root, and ſometimes have one or two ſmall leaves toward the bottom, where they often divide into two naked foot-ſtalks, each being terminated by a bunch of pale reddiſh flowers, which ſmell ſweet at night.

The thirty-ſeventh ſort hath oblong tuberous roots, from which come out ſeveral decompounded winged leaves, ending in many acute points; the ſegments of theſe leaves are broader than thoſe of the thirty-fifth ſort, and the leaves are very hairy. The ſtalks riſe a foot and a half high, which are garniſhed with a ſingle leaf at the two lower joints; theſe are ſingly winged, and the lobes are narrow, ſtanding at a wider diſtance, and the ſegments are more acute than thoſe of the lower leaves; at the two lower knots or joints, ariſe two long naked foot-ſtalks, each being terminated by a bunch of yellowiſh flowers, which have long tubes, and ſmell ſweet in the evening when the ſun has left them. This grows naturally at the Cape of Good Hope.

The thirty-eighth ſort hath a tuberous root like the former, from which ſpring out many hairy leaves, which are finely divided like thoſe of the Pulſatilla, which have a hoary appearance, and riſe immediately from the root, ſpreading on every ſide near the ground. The foot-ſtalk of the flower is naked, and riſes from the root; this grows about nine inches high, and is terminated by a looſe bunch of flowers, which are of a very dark purple colour, and ſmell ſweet in the evening.

The thirty-ninth ſort hath fleſhy tuberous roots like thoſe of the former ſorts, from which come out three or four broad leaves, divided on their borders into ſeveral lobes, in form of a Vine leaf; theſe ſpread flat on the ground; they are hairy, and crenated on their edges, ſtanding upon ſhort foot-ſtalks. The foot-ſtalks of the flowers ariſe immediately from the root, and grow about a foot high; they are naked, and are terminated by a bunch of dark purple flowers, with long tubes, ſitting cloſe to the foot-ſtalks, which have a very agreeable odour in the evening.

The four firſt ſorts of tuberous-rooted Crane's-bill, are by Linnæus ſuppoſed to be but one ſpecies; but I have propagated them from ſeeds ſeveral times, and have never found either of them vary from their parent plants, ſo I make no doubt of their being diſtinct ſpecies, for their difference of leaves is as great as in any of the other ſpecies.

The fortieth ſort is an annual plant, which grows naturally at the Cape of Good Hope; this riſes with herbaceous branching ſtalks near a foot high, which are garniſhed with doubly-winged leaves at each joint; the lower leaves ſtand upon long foot-ſtalks, but thoſe on the upper part ſit cloſe to the ſtalks. The flowers ſtand upon naked foot-ſtalks, which proceed from the ſide of the ſtalks, on the oppoſite ſide to the leaves; they grow three or four together upon ſhort ſeparate foot-ſtalks; theſe are ſhaped ſomewhat like a papilionaceous flower; the two upper petals, which are large, form a kind of ſtandard, the other three petals are narrow, and reflexed downward; they are of a pale fleſh colour, appearing in July, and the ſeeds ripen in September, ſoon after which the plants decay.

The forty-firſt ſort hath a pretty thick tuberous root, from which is ſent out ſeveral irregular ſtalks, which divide into branches, and grow diffuſed; theſe have ſwelling joints, and are ſomewhat ligneous; they are garniſhed with one double winged leaf at each of the joints, and oppoſite to the leaves come out the foot-ſtalks of the flowers; thoſe which are ſituated on the lower part of the ſtalk, are very long and naked, but thoſe which terminate the branches are ſhorter, and have one or two ſmall leaves ſet at their baſe; theſe foot-ſtalks are terminated by a ſmall bunch of flowers, ſhaped like thoſe of the former ſort, but larger, and of a paler colour; theſe continue in ſucceſſion moſt part of the ſummer: this and the former ſort are ſuppoſed to be the ſame by Dr. Linnæus, but the former is an annual plant in every country, periſhing ſoon after the ſeeds are perfected, and the latter is an abiding plant with ligneous ſtalks.

The forty-ſecond ſort is a biennial plant, which grows naturally at the Cape of Good Hope; this ſends out a great number of very ſlender trailing ſtalks, which are proſtrate on the ground, and extend a foot and a half in length, garniſhed with ſmall, roundiſh, hand-ſhaped leaves, which are crenated on their edges. The flowers ſit upon ſhort ſlender foot-ſtalks, which come out at every joint from the ſide of the ſtalks; they are very ſmall, and of a reddiſh colour; ſometimes they are ſingle, and at other times there are two or three flowers upon a foot-ſtalk. They continue in ſucceſſion all the ſummer, and the ſeeds ripen in about five weeks after the flowers decay.

The forty-third ſort hath a ſhrubby ſtalk, which riſes to the height of four or five feet, ſending out ſeveral branches, which are garniſhed with oblong leaves, indented, and unequally ſawed on their edges; the flowers ſtand upon long foot-ſtalks, which come out from the ſide of their branches; they are large, of a red colour, and the two upper petals are larger than the other; this ſort flowers in June and July.

The forty-fourth ſort grows naturally in the iſle of Chio in the Levant. This is an annual plant, which ſends out ſeveral branches a foot long; the lower leaves are almoſt heart-ſhaped, but thoſe on the branches are formed in the ſhape of an ancient lyre. Theſe are placed alternate on the branches; the foot-ſtalks of flowers are produced on the ſide of the branches, theſe are ſix inches long, ſuſtaining many bright purple flowers at the top, which are ſucceeded each by five ſeeds, having long ſlender beaks; theſe ripen in five or ſix weeks after the flowers fall away, and if they are permitted to ſcatter, the young plants will come up in the autumn; and if the winter is favourable, they will live in the open air, ſo will flower early the following ſpring: but if theſe ſhould be killed in the winter, ſome ſeeds ſhould be ſown in the ſpring, on a border of light ground, and when the plants come up they ſhould be thinned, and kept clear from weeds; theſe will flower in July, and their ſeeds will ripen in Auguſt.

The forty-fifth ſort grows naturally in Portugal and Spain; this is an annual plant, whoſe lower leaves are heart-ſhaped, and divided into three lobes; the foot-ſtalks of the flowers are placed on the ſide of the branches, which extend a foot and a half each way; theſe incline to the ground. The foot-ſtalks ſuſtain many bright red flowers, which are ſucceeded each by five ſeeds, having pretty long beaks. This flowers and ſeeds about the ſame time as the former ſort, and requires the ſame culture.

The forty-ſixth ſort grows naturally in Egypt. This is an annual plant, having oval ſawed leaves of a gray colour; the branches extend a foot in length, adorned with ſmall leaves placed alternate, and toward the end have three or four foot-ſtalks produced from their ſides, ſuſtaining ſeveral pale blue flowers, which are each ſucceeded by five ſeeds, having long feathery beaks.

This ſort is much tenderer than the two former, therefore if the ſeeds are ſown on a moderate hot-bed in the ſpring, and when the weather becomes warm, the plants are carefully tranſplanted on a ſheltered border, there will be greater certainty of their perfecting ſeeds.

The forty-ſeventh ſort grows naturally in Carolina, and is an annual plant, greatly reſembling our common Dove's-foot Crane's-bill, but is ſmaller, and the branches are ſhorter; the flowers are very ſmall, of a pale blue colour; theſe are ſucceeded by five ſeeds, having ſhort erect beaks, which are black. If the ſeeds of this ſort are permitted to ſcatter, the plants will ariſe without farther care; and if thinned and kept clean from weeds, will produce flowers and ſeeds.

The forty-eighth ſort has ſome reſemblance of the forty-fifth, but the leaves are more of an oval heart-ſhape; the flowers are alſo of a bright red colour. This grows naturally at the Cape of Good Hope; the plant is tender, therefore will require the ſame treatment as the forty-ſeventh ſort, with which they will produce flowers and ſeeds, after which the plants decay.

All the ſorts of African Crane's-bill may be propagated by ſeeds; theſe may be ſown upon a bed of light earth toward the end of March, where the plants will appear in a month or five weeks after, and by the beginning of June the plants will be fit to remove; when they ſhould be carefully taken up, and each planted into a ſeparate pot, filled with light kitchen-garden earth, and placed in a ſhady ſituation till the plants have taken new root; then they may be removed into a ſheltered ſituation, and placed among other of the hardier green-houſe plants, where they may remain till autumn, when they muſt be removed into the green-houſe, and treated in the ſame manner as other hardy kinds of green-houſe plants.

But thoſe who are deſirous to have their plants large, and flower ſoon, ſow the ſeeds upon a moderate hot-bed in the ſpring, on which the plants will come up much ſooner, and will be fit to remove long before thoſe which are ſown in the open air; but when theſe plants come up, there muſt be great care taken not to draw them up weak; and when theſe are tranſplanted, the pots ſhould be plunged into another moderate hot-bed, obſerving to ſhade them from the ſun till they have taken new root; then they muſt be gradually inured to bear the open air, into which they ſhould be removed the beginning of June, and placed in a ſheltered ſituation with other exotic plants. If theſe plants are brought forward in the ſpring, moſt of the ſorts will flower the ſame ſummer, and the plants will be very ſtrong before the winter, ſo will make a better appearance in the green-houſe.

The ſhrubby African Geraniums, from the twenty-firſt to the thirty-ſecond incluſive, and alſo the forty-firſt and forty-third ſorts, are commonly propagated by cuttings, which, if planted in a ſhady border in June or July, will take good root in five or ſix weeks, and may then be taken up and planted into ſeparate pots, placing them in the ſhade till they have taken new root; after which they may be removed into a ſheltered ſituation, and treated in the ſame manner as the ſeedling plants. The twenty-ninth, thirtieth, thirty-firſt, and thirty-ſecond ſorts, have more ſucculent ſtalks than either of the other, ſo the cuttings of theſe ſorts ſhould be planted into pots filled with light kitchen-garden earth, and plunged into a very moderate hot-bed, where they ſhould be ſhaded from the ſun in the heat of the day, and ſhould have but little water; for theſe are very apt to rot with much moiſture, ſo they muſt only be gently refreſhed now and then with water. When theſe are well rooted, they may be ſeparated and planted in pots filled with the ſame ſort of earth, and placed in the ſhade till they have taken new root; then they may be removed into a ſheltered ſituation, where they may remain till autumn. Theſe four ſorts ſhould be ſparingly watered at all times, but eſpecially in the winter, for they are apt to take a mouldineſs with moiſture, or in a damp air: they will thrive much better in an airy glaſs-caſe than in a green-houſe, becauſe in the former they will have more ſun and air than in the latter, ſo will not be ſo liable to have a mouldineſs or rot. But all the other ſhrubby ſorts are proper furniture for the green-houſe, where they will only require protection from froſt, but ſhould have a large ſhare of free air when the weather is mild; they will require water every week, in mild weather once or twice, but it ſhould not be given them in too great plenty, eſpecially in froſty weather. Theſe plants ſhould be hardened in the ſpring gradually, and toward the middle or latter end of May, they may be taken out of the green-houſe, and at firſt placed under the ſhelter of trees, where they may remain a fortnight or three weeks to harden; then ſhould be removed into a ſituation where they may be defended from ſtrong winds, and enjoy the morning ſun till eleven o'clock, where they will thrive better than in a warmer ſituation.

As theſe ſhrubby ſorts grow pretty faſt, ſo they ſoon fill the pots with their roots; and if they ſtand long unremoved in ſummer, they frequently put out their roots through the holes at the bottom of the pots into the ground, and then the plants will grow vigorouſly; but when they are ſuffered to grow long in this manner, it will be difficult to remove them, for if their roots are torn off, all the younger branches will decay, and many times the plants are killed. Therefore the pots ſhould be moved once in a fortnight or three weeks, in the ſummer months, and the roots which may be then puſhing through the holes in the pots cut off, to prevent their ſtriking into the ground. Theſe plants will alſo require to be new potted at leaſt twice in the ſummer; the firſt time ſhould be after they have been three weeks or a month out of the green-houſe; the ſecond ſhould be towards the end of Auguſt, or the beginning of September, that the plants may have time to eſtabliſh their new roots before they are removed into the green-houſe.

When theſe are new potted, all the roots on the outſide of the balls of earth ſhould be carefully pared off, and as much of the old earth drawn away from the roots, as can be done with ſafety to the plants; then if they require it, they ſhould be put into pots a ſize larger than thoſe out of which they were taken, putting a quantity of freſh earth into the bottom of the pot; then place the plants upon that, being careful the ball about the roots of the plant is not ſo high as the rim of the pot, that ſome room may be left to contain the water which may be given to the plants. Then the cavity all round the ball ſhould be filled up with freſh earth, which ſhould be gently preſſed down, and the bottom of the pot beaten upon the ground, to ſettle down the earth; then the plant ſhould be well watered, and the ſtem faſtened to a rail, to prevent the wind from diſplacing of the root before they are fixed in the new earth.

The compoſt in which I have always found theſe plants thrive beſt (where there has not been a conveniency of getting ſome good kitchen-garden earth) was freſh hazel loam from a paſture, mixed with a fourth or fifth part of rotten dung; if the earth is inclinable to bind, then a mixture of rotten tan is preferable to dung; but if it is light and warm, then a mixture of neat's-dung is beſt: this compoſt ſhould be mixed three or four months before it is uſed, and ſhould be turned over three or four times, that the parts may be well mixed and incorporated; but where a quantity of good kitchen-garden earth can be had, which has been well worked, and is clean from the roots of bad weeds, there will need no compoſition, for in that they will thrive full as well as in any mixture which can be made for them, eſpecially if the earth has lain in a heap for ſome time, and has been two or three times turned over to break the clods, and make it fine: theſe plants ſhould not be planted in very rich earth, for that will cauſe them to grow very luxuriant, but they will not flower ſo well as in a poorer ſoil.

The thirty-third ſort hath herbaceous ſtalks, ſo is beſt propagated by ſeeds, which the plants produce in great plenty; but the cuttings of this will take root as freely as either of the other, but the ſeedling plants are preferable to thoſe propagated by cuttings; and where the ſeeds of this and many other of the African ſorts are permitted to ſcatter, there will be a ſupply of young plants come up the ſpring following, provided the ſeeds are not buried too deep in the ground.

The thirty-fourth ſort may be propagated by ſeeds, or from heads ſlipped off from the ſhort fleſhy ſtalk; theſe heads ſhould have their lower leaves ſtripped off, that the ſtalk which is to be planted may be clear of leaves; then they may be planted ſingle into a ſmall pot, or if the heads are ſmall, there may be two or three put into one ſmall pot; then they may be plunged into a very moderate hot-bed, which will forward their putting out roots, and if they are ſhaded from the ſun and gently refreſhed with water, they will take root in a month or five weeks, when they muſt be hardened gradually, and removed into the open air, where they may remain till autumn, when they muſt be removed into ſhelter for the winter ſeaſon.

The thirty-fifth, thirty-ſixth, thirty-ſeventh, thirty-eighth and thirty-ninth ſorts are generally propagated by parting of their roots; the beſt time for doing this is in Auguſt, that the young roots may be eſtabliſhed before the cold comes on. Every tuber of theſe roots will grow, provided they have a bud or eye to them; they may be planted in the ſame ſort of earth as was before directed, and if the pots are plunged into an old tan-bed, under a good frame in winter, the plants will thrive better than in a green-houſe; the glaſſes of the frame may be drawn off every day in mild weather, whereby the plants will enjoy the free air; and if in hard froſt the glaſſes are well covered to prevent the cold penetrating to the plants, it is all the ſhelter they will require; but in this ſituation they ſhould have but little wet in winter, therefore the glaſſes ſhould be kept over them in heavy rains to keep them dry; but in mild weather the glaſſes may be raiſed on the upper ſide to admit the freſh air to the plants, which will give them greater ſlope to carry off the wet. With this management the roots will thrive and flower very ſtrong every year. Theſe ſorts may alſo be propagated by ſeeds.

The fortieth ſort is an annual plant, and is only propagated by ſeeds, which ſhould be ſown upon a gentle hot-bed in the ſpring, to bring the plants forward; otherwiſe if the ſeaſon ſhould not prove very warm, the plants will not perfect their ſeeds in this country. When the plants are come up, and grown ſtrong enough to remove, they ſhould be each planted into a ſeparate ſmall pot, and plunged into a moderate hot-bed again, obſerving to ſhade them till they have taken new root; then they muſt be gradually hardened to bear the open air, into which they ſhould be removed in June; and when the plants have filled the ſmall pots with their roots, they ſhould be ſhaken out, and the ball of earth preſerved to their roots, and put into pots a ſize larger, in which they will flower and ripen ſeeds, and ſoon after the plants will decay.

The forty-ſecond ſort is alſo propagated by ſeeds, which may be either ſown upon a moderate hot-bed in the ſpring, or upon a bed of light earth in the open air, where the plants will come up very well, though they will not be ſo forward as thoſe on the hot-bed. Thoſe which are ſown in the open air will require no other care but to keep them clean from weeds, and thin the plants where they are too cloſe. Theſe plants will flower in July and Auguſt, and if the autumn proves favourable, the ſeeds will ripen in September; but if theſe ſhould fail, thoſe which were raiſed on the hot-bed will come earlier to flower, ſo there will be no danger of their perfecting ſeeds; and theſe plants, if they are in pots, may be preſerved through the winter, if they are plunged into an old tan-bed under a frame, and treated in the ſame manner as the tuberous-rooted ſorts before mentioned.

The ſhrubby ſorts muſt be looked over frequently during the winter, while they are in the green-houſe, to pick off all decayed leaves from them, which, if left on, will not only render the plants unſightly, but by their falling off, they will occaſion litter among the other plants; and if they are ſuffered to rot in the houſe, they will occaſion a foul, naſty, damp air, which will be very prejudicial to all the plants; therefore to avoid this, they ſhould be conſtantly picked off every week; and during the ſummer ſeaſon, they will require to be picked every fortnight or three weeks to keep them clean from dead leaves; for as the branches advance, and new leaves are produced on their top, the under ones as conſtantly decay; and if left on till they drop off, will render the plants very unſightly.

GERMANDER. See TEUCRIUM.

GEROPOGON. Goat's-beard.

The CHARACTERS are,

The empalement is ſingle, compoſed of many keel-ſhaped leaves which are longer than the corolla; the flower is compoſed of ſeveral hermaphrodite florets, which are imbricated and ſhorter than the empalement, and are of one petal, divided into five ſegments at the top. Theſe have each five ſhort ſtamina, terminated by cylindrical ſummits, and an oblong germen with a ſlender ſtyle, ſupporting two thread-like ſtigma which are recurved; the ſeeds are included in the empalement, and are crowned by five bearded ſpreading rays.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia Æqualis, the florets having five connected ſtamina, and are fruitful.

The SPECIES are,

1. GEROPOGON (*Glabrum*) foliis glabris. Lin. Sp. 1109. *Goat's-beard with ſmooth leaves.* Tragopogon gramineo folio glabrum, flore dilute incarnato. Raii Sup. 149.
2. GEROPOGON (*Hirſutum*) foliis piloſis. Lin. Sp. 1109. *Goat's-beard with hairy leaves.* Tragopogon gramineo folio, ſuave rubente flore. Col. Ecphr. 1. p. 232.

The firſt ſort grows naturally in Italy; this hath an erect ſtalk more than a foot high, garniſhed with ſmooth, Graſs-like, long leaves; the ſtalk branches upward into two or three diviſions, each being terminated by one fleſh-coloured flower, compoſed of ſeveral florets.

The ſecond ſort grows naturally in Italy and Sicily. This riſes with an erect ſtalk a foot high, garniſhed with hairy narrow leaves, and ſeldom divides into branches, but is terminated by one flower compoſed of four or five hermaphrodite florets, which are ſucceeded by ſo many bearded ſeeds.

Theſe plants require the ſame treatment as the TRAGOPOGON, to which article the reader is deſired to turn for their culture.

GESNERA. Plumier Nov. Gen. 27. tab. 9. Lin. Gen. Plant. 667. This plant was ſo named by father Plumier, who diſcovered it in America, in honour of Conrad Geſner, a very learned botaniſt, and natural hiſtorian.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five acute parts at the top, and is permanent, in which is ſituated the germen; the flower hath one petal which is tubulous, and firſt bent inward, and afterward out again like a bugle-horn; the brim is divided into five obtuſe ſegments which are equal; it hath four ſtamina which are ſhorter than the petal, terminated by ſingle ſummits; the germen which ſits under the petal ſupports a ſingle crooked ſtyle, crowned by a headed ſtigma. The germen afterward becomes a roundiſh capſule with two cells, filled with ſmall ſeeds, which are fixed on each ſide the partition.

This genus of plants is ranged in the ſecond ſection of Linnæus's fourteenth claſs, intitled Didynamia Angioſpermia, which includes thoſe plants whoſe flowers have two long and two ſhorter ſtamina, and the ſeeds are included in a capſule.

The SPECIES are,

1. GESNERA (*Tomentoſa*) foliis ovato-lanceolatis crenatis hirſutis, pedunculis lateralibus longiſſimis corymbiferis. Hort. Cliff. 318. *Geſnera with oval, hairy, crenated leaves, and long foot-ſtalks proceeding from the ſides of the ſtalks, ſupporting flowers in a corymbus.* Geſnera amplo digitalis folio tomentoſo. Plum Gen. 27.

2. GESNERA (*Humilis*) foliis lanceolatis ſerratis ſeſſilibus, pedunculis ramoſis multifloris. Lin. Sp. Plant. 612. *Geſnera with ſpear-ſhaped ſawed leaves ſitting cloſe to the ſtalks, and branching foot-ſtalks having many flowers.* Geſnera humilis flore flaveſcente. Plum. Nov. Gen. 27. *Low Geſnera with a yellowiſh flower.*

The firſt ſort grows naturally in the Weſt-Indies; the ſeeds of this were ſent me from Jamaica, which ſucceeded in the Chelſea garden; this riſes with a ſhrubby ſtalk to the height of ſix or ſeven feet, which divides into two or three irregular branches, covered with a ruſſet wool, and garniſhed with hairy leaves which are ſeven or eight inches long, and two and a half broad in the middle, having a ruſſet woolly midrib, and the edges are crenated; theſe are placed on every ſide the branches without order, and have ſhort foot-ſtalks; towards the end of the branches come out the foot-ſtalks of the flowers at every joint, ariſing from the wings of the ſtalk; they are naked, and nine inches in length, branching at the top into many ſmaller foot-ſtalks, each ſuſtaining a ſingle flower, having a ſhort crooked tube, indented at the top in five obtuſe parts, and of an obſolete purple colour. Theſe are ſucceeded by roundiſh capſules ſitting cloſe in the empalement, the diviſions of which ariſe above the capſule; which Dr. Linnæus, from Plumier's figure, has taken for the empalement ſitting upon the capſule, whereas the capſule is dictinct from the empalement and is incloſed by it. The capſule is divided into two cells which are filled with ſmall ſeeds. It flowers here in July and Auguſt, but hath not ripened ſeeds.

The ſecond ſort is a plant of humbler growth; this ſeldom riſes more than three feet high; the leaves are much ſmaller, are ſawed on their edges, and ſit cloſe to the ſtalk; the flowers ſtand upon branching foot-ſtalks, each ſuſtaining many yellowiſh flowers, which are deeper cut at their brims than thoſe of the firſt ſort. This was found growing naturally by the late Dr. Houſtoun at Carthagena in New Spain.

There is a third ſpecies of this genus mentioned by Plumier, which grows to to a tree, and hath ſpotted and fringed flowers; but this I have not ſeen in any of the Engliſh gardens. Theſe plants are propagated by ſeeds, which muſt be procured from the countries where they grow naturally; theſe ſhould be brought over in their capſules, which is the beſt way to preſerve the ſeeds good; for as they are very ſmall and light, ſo when they are ſeparated from the partition to which they adhere, they ſoon loſe their vegetative quality; for I have received the ſeeds ſeveral times from America, which were taken out of the veſſels, but not one of them grew, till I procured ſome to be ſent in their veſſels, which ſucceeded very well.

The ſeeds ſhould be ſown in pots filled with light earth, and plunged into a hot-bed of tanners bark as ſoon as they arrive, for they ſometimes lie long in the ground; thoſe which I have ſown in autumn, came up the following ſpring; therefore when they happen to arrive here at that ſeaſon, the pots in which the ſeeds are ſown ſhould be plunged into the tan-bed in the ſtove, and during the winter the earth ſhould be now and then gently watered to prevent its drying too much, but it muſt not be too moiſt. In the ſpring the pots ſhould be removed out of the ſtove, and plunged into a freſh hot-bed, which will bring up the plants ſoon after. When theſe are fit to remove, they ſhould be each planted into a ſeparate pot, and plunged into a good hot-bed of tan, obſerving to ſhade them till they have taken new root; then they muſt be treated in the ſame way as other tender plants from the ſame countries.

In autumn they muſt be plunged into the tan-bed in the ſtove, where, during the winter, they ſhould have but little water given to them; for if they receive much wet, it will deſtroy them. In this ſtove the plants muſt conſtantly remain, for they will not thrive if they are kept out of the tan. In the ſummer, they ſhould have free air admitted to them at all times when the weather is warm; and they muſt be frequently refreſhed with water during that ſeaſon, but it muſt not be given to them in too great plenty. As the plants advance in growth they will require larger pots, but there muſt be care taken not to over-pot them, for they will not thrive in large pots. With this management the plants will flower the ſecond year, and may be continued three or four years, but they are not of long duration in their native country.

GEUM. Lin. Gen. Plant. 561. Caryophyllata. Tourn. Inſt. R. H. 294. tab. 151. Avens, or Herb Bennet; in French, *Benoite.*

The CHARACTERS are,

The flower hath a one-leaved empalement, cut at the top into ten ſegments, which are alternately ſmaller than the other. The flower has five roundiſh petals, which are narrow at their baſe, where they are inſerted in the empalement; it hath a great number of awl-ſhaped ſtamina, which are the length of the empalement, into which they are inſerted, and are terminated by broad obtuſe ſummits. In the center of the flower is ſituated a great number of germen collected into a head; theſe have ſtyles inſerted in their ſides, which are long, hairy, and crowned by ſingle ſtigmas. The germen afterward become ſo many flat rough ſeeds, which are hairy, and have the ſtyle which is bent like a knee adhering to them; theſe ſit in the common empalement.

This genus of plants is ranged in the fifth ſection of Linnæus's twelfth claſs, intitled Icoſandria Polygynia, in which he places thoſe plants whoſe flowers have more than twenty ſtamina, and have many ſtyles inſerted into the empalement.

The SPECIES are,

1. GEUM (*Urbanum*) floribus erectis, fructu globoſo, ariſtis uncinatis nudis, foliis lyratis. Hort. Cliff. 195. *Geum with erect flowers, a globular fruit, naked hooked beards, and harp-ſhaped leaves.* Caryophyllata vulgaris. C. B. P. 321. *Common Avens, or Herb Bennet.*

2. GEUM (*Rivale*) floribus nutantibus, fructu oblongo, ariſtis plumoſis. Hort. Cliff. 195. *Geum with nodding flowers, and an oblong fruit with feathery beards.* Caryophyllata aquatica, nutante flore. C. B. P. 321. *Aquatic Herb Bennet with a nodding flower.*

3. GEUM (*Pyrenaicum*) floribus nutantibus, fructu globoſo, ariſtis nudis, foliis lyratis, foliolis rotundioribus. *Geum with nodding flowers, a globular fruit with naked beards, and harp-ſhaped leaves with rounder lobes.* Caryophyllata Pyrenaica, ampliſſimo & rotundiori folio, nutante flore. Tourn. Inſt. R. H. 295. *Pyrenean*

Avens with a very large and rounder leaf, and a nodding flower.

4. Geum (*Montanum*) flore erecto ſolitario fructu oblongo, ariſtis plumoſis. Lin. Sp. Plant. 501. *Geum with a ſingle upright flower, and an oblong fruit with feathery beards.* Caryophyllata montana flore luteo magno. J. B. 2. p. 398. *Mountain Avens with a large yellow flower.*

5. Geum (*Alpinum*) flore ſolitario erecto, fructu globoſo, ariſtis tenuioribus nudis. *Geum with a ſingle erect flower, and a globular fruit with narrower naked beards.* Caryophyllata alpina minor. C. B. P. 322. *Smaller Alpine Avens.*

6. Geum (*Virginianum*) floribus erectis, fructu globoſo, ariſtis uncinatis nudis, foliis ternatis. Hort. Cliff. 195. *Geum with upright flowers, a globular fruit with naked beards and trifoliate leaves.* Caryophyllata Virginiana, albo flore minore, radice inodorâ, H. L. 111. *Virginia Avens with a ſmaller white flower, and a root without ſcent.*

The firſt ſort grows plentifully by the ſide of hedges, and in woods, in moſt parts of England, ſo is rarely admitted into gardens. This ſtands in the liſt of medicinal plants; the root is the only part uſed, which is eſteemed cephalic and alexipharmic, and is manifeſtly of a binding nature, ſo is uſeful in all fluxes, &c.

The ſecond ſort grows naturally in moiſt meadows in the northern parts of England. This is of an humbler growth than the firſt, the lower leaves have two pair of ſmall lobes at bottom, and three large ones at the top, that which terminates being the largeſt. The leaves upon the ſtalks are compoſed of three acute lobes which ſit cloſe to the ſtalk; the flowers are of a purpliſh colour, and nod on one ſide; they appear in May, and the ſeeds ripen in July.

The third ſort grows upon the Alps, and alſo on the mountains in the north; this hath ſome reſemblance to the ſecond, but the leaves are much larger and rounder, and are indented on their edges; the flowers are larger and of a gold colour. This flowers about the ſame time as the ſecond.

The fourth ſort grows naturally upon the Alps; this hath leaves much larger than either of the other ſpecies; the lower leaves are compoſed of three or four pair of ſmall irregular pinnæ ſet along the midrib, which is terminated by one very broad roundiſh lobe, which is crenated on the edge. The flowers are large, of a bright yellow colour, ſtanding ſingle on the top of the ſtalk, which ſeldom riſes more than five or ſix inches high. It flowers in May and June.

The fifth ſort grows naturally on the Alps; it is a very low plant, the flower-ſtalks are about three inches long, and bend on one ſide; they are each terminated by one bright yellow flower, about the ſize of thoſe of the common ſort. This flowers about the ſame time as the former.

The ſixth ſort grows naturally in North America; the ſtalks of this ſort riſe a foot and a half or two feet high, and branch out at the top into ſmall footſtalks, each being terminated by a ſmall white flower; the leaves of this ſort are trifoliate, and the root has no ſcent. Theſe are all very hardy plants which require a ſhady ſituation, but will thrive in any ſoil; they may be eaſily propagated by ſeeds, which ſhould be ſown in autumn; for when they are ſown in the ſpring, they do not grow the ſame year.

GILLIFLOWER, or JULY-FLOWER. See Dianthus.

GILLIFLOWER, or STOCK-GILLIFLOWER. See Cheiranthus.

GILLIFLOWER, the Queen's or Dame's Violet. See Hesperis.

GINGER. See Amomum.

GINGIDIUM. See Artedia.

GLADE is an open and light paſſage made through a wood, by lopping off the branches of trees along that way.

GLADIOLUS. Lin. Gen. Plant. 55. Tourn. Inſt. R. H. 365. tab. 190. [takes its name of Gladius, *Lat.* ſword; q. d. little ſword; becauſe the leaves of this plant reſemble a ſword.] Cornflag; in French, *Glaieul.*

The Characters are,

The flowers are included in ſheaths, which ſtand at a diſtance from each other; the petal of the flower is cut into ſix parts, three of the upper are near together, the three under ſpread open, but they all form a ſhort incurved tube with their baſe; they have three awl-ſhaped ſtamina, which are inſerted into every other petal, and all of them aſcend to the upper petals, and are terminated by oblong ſummits. The germen is ſituated below the flower, ſupporting a ſingle ſtyle the length of the ſtamina, crowned by a concave trifid ſtigma. The germen afterward becomes an oblong, ſwelling, three-cornered capſule, with three cells, opening with three valves, filled with roundiſh ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's third claſs, intitled Triandria Monogynia, which includes thoſe plants whoſe flowers have three ſtamina and one ſtyle.

The Species are,

1. Gladiolus (*Communis*) foliis enſiformibus, floribus diſtantibus, Lin. Sp. Plant. 36. *Cornflag with Swordſhaped leaves and flowers ſtanding at a diſtance.* Gladiolus floribus uno verſu diſpoſitis. C. B. P. 41. *Cornflag with flowers diſpoſed on one ſide the ſtalk.*

2. Gladiolus (*Italicus*) foliis enſiformibus, floribus ancipitibus. *Cornflag with ſword-ſhaped leaves, and flowers ſtanding on both ſides the ſtalk.* Gladiolus utrinque floribus. C. B. P. 41. *Cornflag with flowers on each ſide the ſtalk.*

3. Gladiolus (*Byzantinus*) foliis enſiformibus, ſpathis longioribus. *Cornflag with ſword-ſhaped leaves and longer ſheaths to the flowers.* Gladiolus major Byzantinus. C. B. P. 41. *Greater Cornflag of Byzantium.*

4. Gladiolus (*Indicus*) foliis enſiformibus, floribus maximis incarnatis. *Cornflag with ſword-ſhaped leaves, and very large incarnate flowers.* Gladiolus maximus Indicus. C. B. P. 41. *Greateſt Indian Cornflag.*

5. Gladiolus (*Anguſtis*) foliis linearibus floribus diſtantibus, corollarum tubo limbis longiore. Lin. Sp. Plant. 37. *Cornflag with very narrow leaves, flowers ſtanding at a diſtance from each other, and the tube longer than the margins of the petal.* Gladiolus Africanus, folio gramineo, floribus carneis, maculam rhomboideam inſcriptis uno verſu poſitis. Boerh. Ind. alt. 2. 127. *African Cornflag, with a graſſy leaf, and fleſh-coloured flowers, marked with a purple rhomboid ſpot ranged all on one ſide the ſtalk.*

6. Gladiolus (*Triſtis*) foliis lineari cancellatis corollis campanulatis. *Cornflag with very narrow channelled leaves, and a ſtalk bearing bell-ſhaped flowers.* Lilio-Gladiolus bifolius & biflorus, foliis quadrangulis. Trew. tab. 39. *Lily Cornflag with two leaves and flowers, and four-cornered leaves.*

The firſt ſort grows naturally in arable land in moſt of the warm countries in Europe, and was formerly cultivated in the Engliſh gardens, where the roots have multiplied ſo greatly as to become a moſt troubleſome weed, and are very difficult to eradicate; this hath a round, compreſſed, tuberous root, which is of a yellowiſh colour, covered with a brown furrowed ſkin, like thoſe of the large yellow vernal Crocus; from the root ariſe two flat ſword-ſhaped leaves, which embrace each other at their baſe, and between theſe ariſe the flower-ſtalk, which grows near two feet high, having one or two narrow leaves embracing it like a ſheath; the ſtalks are terminated by five or ſix purple flowers, ſtanding above each other at ſome diſtance, and ranged on one ſide of the ſtalk; each of theſe has a ſpatha (or ſheath) which covers the flower-bud before it expands, but ſplits open lengthways when the flowers blow, and ſhrivel up to a dry ſkin, remaining about the ſeed-veſſel till the ſeeds are ripe. The flower hath one petal, which is cut almoſt to the bottom in ſix parts, ſo as to appear like a flower of ſix petals; the three upper ſegments ſtand near together, and riſe like a labiated flower; the under one turns downward, and the two ſide ſegments form the chaps of the flower, and ſpread open at the top, but

but are curved downward at the bottom. They are ranged along one ſide of the ſtalk, and are of a purpliſh red colour. This flowers the latter end of May, and in June, and the ſeeds ripen the beginning of Auguſt; it requires no care, for when it is once planted in a garden, it will multiply too faſt, ſo as to become a troubleſome weed.

There is a variety of this with white flowers, and another with fleſh-coloured flowers, which have accidentally riſen from ſeeds, ſo are not different ſpecies.

The ſecond ſort differs from the firſt, in having the flowers ranged on both ſides the ſtalk, but in other reſpects it is very like to that; and of this there is a variety with white flowers, but theſe are not ſo common in the Engliſh gardens as the former.

The third ſort hath larger roots than either of the former, but are of the ſame form; the leaves are alſo much broader and longer, the veins or channels of the leaves are deeper, the flower-ſtalks riſe higher; the flowers are much larger, and of a deeper red colour than thoſe of the former ſorts, and the ſheaths are longer. This plant makes a fine appearance in flower, ſo is worthy of a place in every good garden; and the rather, becauſe the roots do not increaſe ſo faſt as to become troubleſome in the borders. This is propagated by offsets, which are ſent off from the roots in the ſame manner as Tulips. The roots may be taken out of the ground the end of July, when their ſtalks decay, and may be kept out of the ground till the latter end of September, or the beginning of October; at which time they ſhould be planted in the borders of the flower-garden, where they will thrive in any ſituation, and being intermixed with other flowers of the ſame growth, they will add to the variety.

The fourth ſort grows naturally at the Cape of Good Hope, from whence I have ſeveral times received the ſeeds. This has been many years cultivated in the Engliſh gardens, but very rarely flowers here; for in near thirty years that I have cultivated this ſort, I have never ſeen it but once in flower, though I have kept it in all ſituations, and planted it in various ſoils. The roots increaſe very faſt, but will not live in the open air through the winter in this country. The roots of this ſort are broader and flatter than thoſe of any of the other ſorts, and are covered with a netted ſkin; the leaves come out in the ſame manner, embracing each other like the former ſorts; they are longer, ſmoother, and of a brighter green, than any of the others; theſe begin to appear in September, and continue growing in ſize till after Chriſtmas; they begin to decay in March, and the latter end of June are quite withered, when the roots may be taken up, and kept out of the ground till Auguſt; the time of its flowering is in January. The flowers of this ſort are placed on each ſide the ſtalk, and ſit cloſe to it, like the grains of the flat Barley; the ſheaths between the flowers are not ſo long as thoſe of the other ſorts, and form a kind of ſcaly covering to them. The flowers are of a pale red colour without, but the three lower ſegments are yellow within toward their baſe, with a few red ſtripes. The flowers do not all open at the ſame time, but the lower ones decay before thoſe on the upper part of the ſpike are in beauty; however, they make a good appearance at a ſeaſon when all flowers are valuable.

This ſort propagates by offsets very faſt; theſe ſhould be planted in a warm border of kitchen-garden earth, and in winter they ſhould be covered with glaſſes or mats to guard them from froſt; for I have with a ſlight ſhelter preſerved thoſe which were in pots under a common frame, and ſome which were planted in the full ground, when the froſt has not been ſevere; and I have always found that thoſe plants which were hardily treated, grew much ſtronger than thoſe which were placed in a moderate degree of warmth; ſo that where there is a conveniency of covering a warm border with glaſſes in the winter, if theſe roots are planted in the full ground, where they may be protected from the froſt, there will be a greater probability of their flowering, than in any other method of culture.

The fifth ſort grows naturally at the Cape of Good Hope, from whence I received the ſeeds, which ſucceeded in the Chelſea garden, where the plants annually produce their beautiful flowers.

This hath a round, ſmooth, bulbous root, which is covered with a thin dark-coloured ſkin, from which come out in autumn two or three very narrow graſſy leaves, folded over each other at their baſe, but open flat above, and riſe near two feet high. In the ſpring of the year ariſes a ſingle ſtalk from between the leaves about two feet long, which always bend on one ſide; toward the upper part of this come out two or three flowers, ranged on one ſide of the ſtalk, ſtanding upright, each having a narrow ſpatha, or hood, and long ſlender tubes, which ſwell large upward, and are divided into ſix parts, which are nearly equal. The flower is of a duſky fleſh colour, and each ſegment of the petal has a rhomboidal mark of a dark red, or purple colour; afterward the tube of the flower opens, and the deep diviſion of the petals is ſeen, and the three ſtamina with their ſummits appear, attended by the ſtyle with its trifid ſtigma, ariſing from the germen. This plant flowers in May and the beginning of June; as this plant is a native of a warm country, it requires protection from the froſt in winter; therefore the bulbs ſhould be planted in pots filled with light earth, and placed in the green-houſe in winter; or, where there is not ſuch conveniency, they may be put under a hot-bed frame during that ſeaſon, where they may have air in mild weather, and be ſcreened from the froſt; in ſuch ſituations I have had them thrive and flower very well.

This is propagated by offsets from the root in the ſame manner as the laſt, and alſo by ſeeds, which are frequently perfected in England; theſe ſhould be ſown the latter end of Auguſt, in pots filled with light earth, and placed in a ſhady ſituation till the middle of September; then the pots ſhould be removed where they may have the ſun great part of the day, and in October they muſt be placed under a hot-bed frame, where they may be protected from froſt and great rains, but enjoy the free air in mild weather. In the ſpring the young plants will appear, when they will require a little water once in eight or ten days; but it ſhould be given them ſparingly, for too much wet will rot theſe tender bulbs. In May, when the danger of froſt is over, the pots ſhould be removed to a ſheltered ſituation, where they may have the morning ſun till noon; and, if the ſeaſon proves dry, they muſt be now and then refreſhed with water. Toward the latter end of June, the leaves of theſe plants will decay; then the roots ſhould be taken up, and may be mixed with ſand, and kept in a dry room till the end of Auguſt, when they ſhould be planted again; and as the roots are ſmall, four or five may be planted in each halfpenny pot, filled with light earth; theſe ſhould be placed where they may have only the forenoon ſun, till the middle of September, when they ſhould have a warmer ſituation; and in October they muſt be placed under a hot bed frame as before, and treated in the ſame way during the winter ſeaſon; and in the ſpring they muſt be placed in the open air till their leaves decay, when they may be again taken out of the ground, and treated in the ſame manner as before; but as the roots will have grown to a larger ſize, ſo when they are planted again, they ſhould each have a ſeparate half-penny pot, becauſe now they will be large enough to flower, ſo may be treated as the old roots.

The ſixth ſort is alſo a native of the Cape of Good Hope, from whence I have ſeveral times received the ſeeds; the root of this ſort is oval, not compreſſed as thoſe of the common ſorts. The leaves are very long and narrow, having two deep furrows running the whole length, the midrib riſing very prominent, ſo as to have the appearance of a four-cornered leaf. The leaves are ſingle, and wrapped cloſe about the flower-ſtalk at their baſe to a conſiderable length; there are ſeldom more than two of theſe leaves from one root; the ſtalk is ſlender and round, and riſes about two feet high; and the top is garniſhed with two flowers, which are placed two inches and a half aſunder on the ſame ſide of the ſtalk, each having a ſhort ſpatha, or ſheath, embracing the germen and the baſe of the tube, which is long, narrow, and recurved, but enlarges greatly before it is divided. The upper part of the flower is cut into ſix equal ſegments, which end in acute points of a purpliſh colour, which form a ſtripe through the middle of each ſegment. The petal is of a cream colour, and fades to a ſulphur colour before it decays. This flowers in June, and ſometimes the ſeeds ripen well in England. This may be propagated by offſets from the root, or by ſeeds in the ſame manner as the fifth ſort, and the plants require the ſame treatment.

GLANDIFEROUS trees, are ſuch trees as bear maſt, as Acorns, &c.

GLANDULOUS roots, are ſuch roots as grow kernel-wiſe.

GLANS is that ſort of fruit which is contained within a ſmooth, but hard bark, having but one ſeed; its hinder parts covered with a kind of cup, the fore-part being bare, as Acorns; but it is properly the fruit without the cup.

GLASTENBURY THORN. See Mespilus.

GLAUCIUM. See Chelidonium.

GLAUX, Sea Chickweed, or Milkwort, and black Saltwort, is a low trailing perennial plant, with leaves ſomewhat like Chickweed, but of a thicker conſiſtence, which ſit cloſe to the ſtalks. The flowers come out from the boſom of the leaves; they are white, and like thoſe of Chickweed. This is ſeldom cultivated in gardens, ſo I ſhall not trouble the reader with a further account of it. This grows upon the ſea-ſhores in moſt parts of England.

GLECHOMA. Ground Ivy, Gill go by the Ground, Ale-hoof, or Turn-hoof.

This plant grows naturally under hedges, and upon the ſides of banks in moſt parts of England, ſo is rarely cultivated in gardens, for which reaſon I ſhall paſs over it, with barely mentioning it here.

GLEDITSIA. Lin. Gen. Plant. 1025. Acacia. Raii Meth. 161. Honey Locuſt, or three-thorned Acacia.

The Characters are,

It hath male and hermaphrodite flowers in the ſame katkin, and female flowers in different plants. The male katkins are long, compact, and cylindrical, and have each a three-leaved ſmall empalement; they have three roundiſh petals, which ſpread open in form of a cup; theſe have a turbinated nectarium, whoſe mouth afterward grows to the parts of fructification; they have ſix ſlender ſtamina, which are longer than the petals, terminated by oblong compreſſed ſummits. The hermaphrodite flowers in the ſame katkin, are ſituated at the end; theſe have empalements, petals, and ſtamina like the male, and have a germen, ſtyle, and ſeeds like the female, which are ſituated on different trees, and are diſpoſed in a looſe katkin; theſe have a five-leaved empalement, and have five oblong petals, with two ſhort thread-like nectariums, and a broad germen longer than the petals, ſupporting a ſhort reflexed ſtyle, crowned by a thick ſtigma. The germen afterward becomes a large flat pod, with ſeveral tranſverſe partitions, having a pulp in each diviſion, ſurrounding one hard roundiſh ſeed.

This genus of plants is ranged in the ſecond ſection of Linnæus's twenty-third claſs, intitled Polygamia Diœceia, which includes thoſe plants which have male and hermaphrodite flowers in the ſame plant, and female flowers in different plants.

The Species are,

1. Gleditsia (*Triacanthus*) ſpinis triplicibus axillaribus. Lin. Sp. 1509. *Gleditſia with three thorns on the ſide of the branches.* Acacia Americana Abruæ folio triacanthos, ſive ad axillas foliorum, ſpinâ triplici donatâ. Pluk. Mant. 1. *Three-thorned American Acacia.*
2. Gleditsia (*Inermis*) ſpinis paucioribus, foliis bipinnatis, ſiliquis ovalibus. *Gleditſia with fewer ſpines, winged leaves, and oval pods.* Acacia Abruæ folio triacanthos, capſulâ ovali unicum ſemen claudente. Cateſb. Car. 1. p. 43. *Three-thorned Acacia with an Abrus leaf, and an oval pod containing one ſeed.*

Theſe trees grow naturally in America; the firſt ſort is very common in moſt parts of North America, where it is known by the title of Honey Locuſt; this has been many years cultivated in the Engliſh gardens, and is known among the gardeners by the title of three-thorned Acacia. It riſes with an erect trunk to the height of thirty or forty feet, and is armed with long ſpines, which have two or three ſmaller coming out from the ſide, and are frequently produced in cluſters at the knots on the ſtems of the trees; they are ſometimes three or four inches long. The branches of this tree are alſo armed with the ſame ſort of ſpines, and are garniſhed with winged leaves, compoſed of ten pair of ſmall leaves which ſit cloſe to the midrib, and are of a lucid green. The flowers come out from the ſide of the young branches in katkins; they are of an herbaceous colour, ſo make no figure. The hermaphrodite flowers are ſucceeded by pods near a foot and a half long, and two inches broad, divided into many cells by tranſverſe partitions, each containing one ſmooth, hard, oblong ſeed, ſurrounded by a ſweet pulp.

The leaves of this tree ſeldom come out till June in this country, and the flowers appear the latter end of July, but they do not flower till they are of a large ſize: there was one tree in the Chelſea garden which produced flowers ſeveral years, and there is one now growing in the Biſhop of London's garden at Fulham, which produced pods in the year 1728, and came to their full ſize, but the ſeeds did not ripen.

The ſecond ſort hath much the appearance of the firſt, but it hath fewer ſpines. The leaves are ſmaller, and the pods are oval, containing but one ſeed; this was diſcovered by the late Mr. Cateſby, in Carolina, from whence he ſent the ſeeds to England, by the title of Water Acacia, by which it is known in the gardens.

Theſe trees are propagated by ſeeds, which muſt be procured from America, where the trees grow naturally; thoſe of the firſt ſort are annually ſent to England in plenty, by the title of Locuſt, or Honey Locuſt, to diſtinguiſh it from the falſe Acacia, which is frequently called Locuſt-tree in America; theſe ſeeds may be ſown upon a bed of light earth in the ſpring, burying them half an inch deep; and if the ſpring ſhould prove dry, they muſt be frequently watered, otherwiſe the plants will not come up the firſt year, for I have ſometimes had the ſeeds remain two years in the ground before they have come up; therefore thoſe who are deſirous to ſave time, ſhould ſow the ſeeds as ſoon as they arrive, and plunge the pots into a moderate hot-bed, obſerving to water them frequently; by this method moſt of the plants will come up the ſame ſeaſon, but theſe ſhould be gradually inured to bear the open air, for if they are continued in the hot-bed, they will draw up weak; during the ſummer ſeaſon, thoſe plants in pots will require frequent waterings, but thoſe in the full ground will not dry ſo faſt, therefore need no water, unleſs the ſeaſon ſhould prove very dry. In autumn, thoſe in the pots ſhould be placed under a hot-bed frame to protect them from froſt, for theſe young plants generally keep growing late in the ſummer, ſo the upper part of their ſhoots is tender, and the early froſts of the autumn often kill the ends of them, if they are not protected, and this frequently occaſions great part of the ſhoots decaying in winter; for which reaſon thoſe plants in the full ground ſhould be covered with mats in autumn, on the firſt appearance of froſt; for a ſmall froſt in autumn will do more miſchief to theſe young ſhoots which are full of ſap, than ſevere froſt when the ſhoots are hardened.

The following ſpring the plants may be tranſplanted into nurſery-beds, at a foot diſtance row from row, and ſix inches aſunder in the rows; but this ſhould not be performed till April, after the danger of hard froſt is over; for as the plants do not put out their leaves till very late, ſo there will be no hazard in removing them any time before May. If the ſeaſon ſhould prove dry, they muſt be watered; and if the ſurface of the beds is covered with moſs, or mulch, to prevent the earth from drying, it will be of great ſervice to the plants. In theſe beds the plants may remain two years, during which time they muſt be conſtantly kept clean from weeds; and in the winter there ſhould be ſome rotten tan, or other mulch, ſpread over the ſurface of the ground to keep out the froſt. If the plants thrive well, they will be fit to tranſplant to the places where they are to remain after two years growth, for they do not bear removing when large; the beſt ſeaſon for tranſplanting of theſe trees, is late in the ſpring; they thrive beſt in a light deep ſoil, for in ſtrong ſhallow ground they become moſſy, and never grow large; they ſhould alſo have a ſheltered ſituation, for when they are much expoſed to winds, their branches are frequently broken in the ſummer ſeaſon, when they are fully clothed with leaves.

GLOBULARIA. Lin. Gen. Plant. 106. Tourn. Inſt. R. H. 466. tab. 265. *Blue Daiſy.*

The Characters are,

It hath a flower compoſed of many florets, which are included in one common ſcaly empalement; each floret has an empalement of one leaf, which is tubulous, and cut into five ſegments at the top. The florets have one petal, whoſe baſe is tubulous, but the brim is cut into four parts; the upper ſegment, which is the leaſt, is reflexed; they have four ſtamina the length of the petal, terminated by diſtinct ſummits; in the bottom of the tube is ſituated an oval germen ſupporting a ſingle ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes an oval ſeed, ſitting in the common empalement.

This genus of plants is ranged in the firſt ſection of Linnæus's fourth claſs, intitled Tetandria Monogynia, which includes thoſe plants whoſe flowers have four ſtamina and one ſtyle.

The Species are,

1. Globularia (*Vulgaris*) caule herbaceo, foliis radicalibus tridentatis, caulinis lanceolatis. Flor. Suec. 109. *Globularia with an herbaceous ſtalk, the lower leaves divided into three points, and thoſe on the ſtalks ſpear-ſhaped.* Globularia vulgaris. Tourn. 467. *Common Globularia.*
2. Globularia (*Nudicaulis*) caule nudo, foliis integerrimis lanceolatis. Lin. Sp. Plant. 97. *Globularia with a naked ſtalk, and ſpear-ſhaped entire leaves.* Globularia Pyrenaica, folio oblongo, caule nudo. Tourn. 467. *Pyrenean Globularia, with an oblong leaf and naked ſtalk.*

Cor. 35. *Eaſtern Globularia with flowers ſcattered along the ſtalks.*

The firſt of theſe plants grows plentifully about Montpelier, as alſo at the foot of the mountains Jura and Saleva, and in many other parts of Italy, and in Germany; this plant hath leaves very like thoſe of the Daiſy, but are thicker and ſmoother. The flower-ſtalks riſe about ſix inches high, ſupporting a globular head of flowers, compoſed of ſeveral florets, which are included in one common ſcaly empalement; they are of a fine blue colour, and appear in June; theſe are ſucceeded by ſeeds, which ſit in the empalement, and ripen in autumn.

The ſecond ſort grows plentifully in the woods, near the convent of the Carthuſians, and on the Pyrenean mountains; this is much larger than the former, and hath a ſhrubby ſtalk a foot and a half high; the foot-ſtalk is quite naked. The leaves are narrower, and much longer.

The firſt ſort may be propagated by parting of the roots after the manner of Daiſies. The beſt ſeaſon for parting and tranſplanting of the plants is in September, that they may take new root before the froſty weather comes on. They ſhould be planted in a ſhady ſituation, and require a moiſt loamy ſoil, in which they will thrive much better than in a light ground and an open ſituation; but the plants ſhould not be removed oftener than every other year, if they are required to flower ſtrong.

The third ſort grows about Montpelier in France, and in Valentia, and ſeveral other parts of Spain. This has a hard woody ſtem, which riſes about two feet high, having many woody branches, beſet with leaves like thoſe of the Myrtle-tree. On the top of the branches the flowers are produced, which are of a blue colour, and globe-ſhaped; this plant may be propagated by cuttings, which ſhould be cut off in April, juſt before they begin to make new ſhoots; the cuttings ſhould be planted into pots filled with light freſh earth, and then placed into a very moderate hot-bed, obſerving to water and ſhade them until they have taken root, when they may be taken out of the bed, and inured to bear the open air by degrees. In ſummer theſe plants may be expoſed with other hardy exotic plants, and in winter they ſhould be placed under a hot-bed frame, where they may enjoy the free air in mild weather, but ſhould be ſcreened from hard froſt, which will deſtroy them, if they are expoſed thereto, but in mild winters they will live in the open air. This plant never produces good ſeeds in this country.

The fourth ſort was found in the mountains of Granada, by Dr. Albinus; this plant is of low growth, and may be propagated as the firſt; as may alſo the fifth ſort, which is the leaſt of all the ſorts, and the moſt hardy; therefore ſhould have a ſhady ſituation, and a cool moiſt ſoil.

The ſixth ſort was found by Dr. Tournefort in the Levant; this is ſomewhat tender, and ſhould be ſheltered from the froſt in winter, under a frame, but in ſummer it ſhould be expoſed with other hardy exotic plants, and will require to be frequently watered in dry weather. This may be propagated by ſeeds, or by parting of their roots, as was directed for the firſt ſort.

GLORIOSA. Lin. Gen. Plant. 374. Methonica. Tourn. Acad. R. Scien. 1706. *The Superb Lily.*

The Characters are,

The flower hath no empalement; it hath ſix long ſpear-ſhaped petals, which are waved, and reflexed to the foot-ſtalk. It hath ſix ſtamina, which ſpread open each way, and are terminated by proſtrate ſummits. In the center is ſituated a globular germen, ſupporting a ſlender inclining ſtyle, crowned by an obtuſe triple ſtigma. The germen afterward becomes an oval thin capſule having three cells, filled with globular ſeeds, diſpoſed in a double range.

This genus of plants is ranged in the firſt ſection of Linnæus's ſixth claſs, intitled Hexandria Monogynia, which includes the plants whoſe flowers have ſix ſtamina and one ſtyle.

1. Glorioſa (*Superba*) foliis longioribus capreolis terminalibus. *Superb Lily with longer leaves ending with claſpers.*

claſpers. Methonica Malabarorum. Hort. Lugd. 688. *Methonica of Malabar*, and the Lilium Zeylanicum ſuperbum. Hort. Amſt. 1. p. 69. *Superb Lily of Ceylon.*

2. Gloriosa (*Cærulea*) foliis ovato-lanceolatis acutis. *Superb Lily with oval, ſpear-ſhaped, acute leaves.*

The firſt ſort grows naturally on the coaſt of Malabar, and alſo in Ceylon, from whence it was firſt brought to the gardens in Holland, where it has been many years cultivated; this hath a long fleſhy root of a whitiſh colour, and a nauſeous bitter taſte, from the middle of which ariſes a round weak ſtalk, which requires ſupport to prevent its trailing on the ground. The ſtalks grow to the height of eight or ten feet, garniſhed with leaves placed alternate on every ſide, which are ſmooth, about eight inches long, and one inch and a half broad at the baſe, growing narrower till within two inches of the end, which runs out in a narrow point, ending with a tendril, or claſper, by which it faſtens to the neighbouring plants for ſupport. At the upper part of the ſtalk the flower is produced from the ſide, ſtanding upon a ſlender foot-ſtalk; it is compoſed of ſix oblong petals, ending with acute points, which, on their firſt opening, are of an herbaceous colour, and ſpread wide open; the flower hanging downward as the Crown Imperial and Fritillary, but afterward the petals turn quite back, and change to a beautiful red flame colour, their acute points meeting at the top; theſe petals are finely waved on their edges. The ſix ſtamina ſpread out every way almoſt horizontal, and are terminated by proſtrate ſummits. In the center of the flower is ſituated a roundiſh germen, ſupporting an inclining ſtyle, crowned by a triple ſtigma. This plant flowers in June and July, but ſeldom perfects ſeeds in this country. The ſtalks decay in autumn, and the roots remain inactive all the winter, and the new ſtalks come out in March. The roots and every part of this plant is very poiſonous, ſo ſhould not be put in the way of children.

The ſeeds of the ſecond ſort were ſent me by Monſ. Richard, gardener to the French king at Trianon; theſe were brought from Senegal by Monſ. Adanſon, who diſcovered this plant growing there naturally; this is ſaid to have a blue flower, but the plants which are in the Chelſea garden have not yet flowered. This hath a climbing ſtalk, which is garniſhed with ſmooth leaves about three inches long, and two broad, ending in acute points, but have no tendril or claſper. The ſtalks as yet have not grown more than two feet high here, but have the appearance of climbing like the other ſort. The leaves have a ſtrong diſagreeable ſcent on being handled, ſo as to be troubleſome to the head if too near, or long ſmelt to.

As theſe plants rarely produce ſeeds in this country, they are generally propagated by their roots; thoſe of the firſt ſort creep and multiply pretty faſt, but the ſecond hath not as yet put out any offſets; but as the plants are young, we cannot as yet ſay how they may increaſe when they are of a proper age. Theſe roots may be taken out of the ground when their ſtalks are decayed, and preſerved in ſand during the winter ſeaſon, but they muſt be kept in the ſtove, or a warm room, where they can receive no injury from the cold; and in the ſpring they muſt be planted in pots filled with light earth, and plunged into the tan-bed in the ſtove; but others chuſe to let the roots continue in the ground all the winter, keeping the pots always in the tan-bed: where this is practiſed, the roots ſhould have very little water in the winter; for as they are then in an inactive ſtate, ſo moiſture at that time frequently rots the roots.

Toward the latter end of March, or the beginning of April, their ſtalks will appear, when there ſhould be ſome tall ſticks put down by them to ſupport them, otherwiſe they will trail over the neighbouring plants, and the firſt ſort will faſten to the plants by the tendrils, which are at the end of the leaves. The ſtalks of this ſort will riſe ten or twelve feet high, if the roots are ſtrong, and ſome of the ſtalks will produce two or three flowers, which come out from the wings of the ſtalk near the top; theſe flowers make a fine appearance in the ſtove, during their continuance, which is ſeldom more than ten days or a fortnight. In ſummer, when the plants are growing, they will require frequently to be watered, but they muſt not have it in too large quantities, for they are very ſubject to rot with much wet at any ſeaſon. Thoſe roots which are not taken out of the pots in winter, ſhould be tranſplanted and parted the beginning of March, before they put out new fibres, or ſtalks, for they muſt not be removed when they are in a growing ſtate; the pots in which theſe roots are planted ſhould not be too large; for unleſs they are confined, they will not put out ſtrong ſtalks; the largeſt roots may be planted in twopenny pots, but the ſmall ones will require only pots of about five or ſix inches over at the top.

GLYCINE. Lin. Gen. Plant. 797. Apios. Boer. Ind. alt. *Knobbed-rooted Liquorice Vetch.*

The Characters are,

The empalement of the flower is of one leaf, divided into two lips at the top, the upper lip being obtuſe and indented; the lower lip is longer, trifid, and acute, the middle indenture being extended beyond the other. The flower is of the butterfly kind. The ſtandard is heart-ſhaped, deflexed on the ſides, gibbous on the back, and indented at the point. The wings are ſmall, oblong, and oval toward their end, and bend backward. The keel is narrow, ſickle-ſhaped, turning upward with its point to the ſtandard, where it is broadeſt. It hath ten ſtamina, nine of which are joined in one body, and the other ſtands ſingle, terminated by ſingle ſummits. In the center is ſituated an oblong germen ſupporting a ſpiral cylindrical ſtyle, crowned by an obtuſe ſtigma. The germen afterward becomes an oblong pod with two cells, incloſing kidney-ſhaped ſeeds.

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, which includes the plants whoſe flowers have ten ſtamina joined in two bodies. Tournefort places the firſt ſort under this genus of Aſtragalus, which is ranged in the fifth ſection of his tenth claſs, which includes the herbs with a butterfly flower, whoſe pointal turns to a pod with two cells.

The Species are,

1. Glycine (*Apios*) foliis impari-pinnatis ovato-lanceolatis. Hort. Upſal. 227. *Glycine with oval, ſpear-ſhaped, winged leaves.* Aſtragalus tuberoſus ſcandens, Fraxini folio. Tourn. Inſt. 415. *Climbing tuberous Milk Vetch with an Aſh leaf*; and the Apios Americana. Cornut. 200.
2. Glycine (*Fruteſcens*) foliis impari-pinnatis caule perenni. Hort. Cliff. 361. *Glycine with winged leaves and a perennial ſtalk.* Phaſeoloides fruteſcens, Caroliniana, foliis pinnatis, floribus cæruleis conglomeratis. Hort. Angl. tab. 15. *Carolina Kidney-bean-tree, with winged leaves, and blue flowers growing in whorls.*

Plant. 754. *Glycine with woolly trifoliate leaves, and very ſhort ſpikes of flowers proceeding from the ſides of the ſtalks, with pods containing two ſeeds.* Anonis phaſeoloides ſcandens, floribus flavis ſeſſilibus. Hort. Elth. 30. tab. 26. *Climbing Reſt-Harrow like Kidney-bean, with yellow flowers ſitting cloſe to the ſtalks.*

The firſt ſort grows naturally in Virginia; this hath roots compoſed of ſeveral knobs, or tubers, which hang to each other by ſmall ſtrings; from theſe come out in the ſpring ſlender twining ſtalks, which riſe to the height of eight or ten feet, garniſhed with winged leaves, compoſed of three pair of oval ſpear-ſhaped lobes, terminated by an odd one. The flowers come out in ſhort ſpikes from the ſide of the ſtalks; they are of a Pea-bloſſom kind, of a dirty fleſh-colour, having little ſcent. Theſe appear in Auguſt, but do not produce ſeeds in England. The ſtalks decay in autumn, but the roots continue; this is propagated by parting of the roots, each of the tubers being ſeparated from the principal root, will grow; the beſt time for this is about the end of March, or the beginning of April, before they put out ſhoots. The roots ſhould be planted in a warm ſituation, and in hard froſt covered with tan or mulch to protect them, otherwiſe they will not live abroad in this country: where they have been planted againſt a ſouth wall, they have thriven and flowered extremely well, which they ſeldom do in any other ſituation; and thoſe roots which are planted in pots rarely flower, nor do their ſtalks riſe near ſo high as thoſe which are planted in the full ground; ſome ignorant perſons call this the Twickenham Climber.

The ſecond ſort was brought from Carolina, but has been ſince obſerved in Virginia, and ſome other places in North America; this ſort has woody ſtalks, which twiſt themſelves together, and alſo twine round any trees that grow near, and will riſe to the height of fifteen feet, or more. The leaves are winged, and in ſhape ſomewhat like the Aſh-tree, but have a greater number of pinnæ. The flowers are produced in cluſters from the wings of the leaves, which are of a purple colour; theſe are ſucceeded by long cylindrical pods, ſhaped like thoſe of the ſcarlet Kidney-bean, containing ſeveral kidney-ſhaped ſeeds, but theſe are never perfected in England.

This climbing ſhrub is propagated in ſeveral nurſeries near London, where it is known by the name of Carolina Kidney-bean-tree. It is increaſed by laying down the young branches in October, which will be rooted well by that time twelvemonth (eſpecially if they are duly watered in dry weather) and may then be tranſplanted, either in a nurſery for a year to get ſtrength, or to the place where they are to remain for good, which ſhould be in a warm light ſoil and a ſheltered ſituation, where they will endure the cold of our ordinary winters very well; and if their roots are covered with ſtraw, Fern, Peas-haulm, or any other light covering, there will be no danger of their being deſtroyed by the froſt.

The third ſort grows naturally in both Indies, and alſo in Egypt. This is a perennial plant, with ſlender twining ſtalks, which twiſt about any neighbouring ſupport, and riſe to the height of eight or ten feet, garniſhed with winged leaves, compoſed of ſixteen pair of ſmall, oblong, blunt lobes, ſet cloſe together; theſe have the taſte of Liquorice, from whence the inhabitants of the Weſt-Indies have given it the name of Wild Liquorice, and uſe the herb for the ſame purpoſe as the Liquorice in Europe. The flowers are produced from the ſide of the ſtalks in ſhort ſpikes or bunches; they are of a pale purple colour, and ſhaped like thoſe of the Kidney-bean; theſe are ſucceeded by ſhort pods, each containing three or four hard round ſeeds of a ſcarlet colour, with a black ſpot or eye on that ſide which is faſtened to the pod. The ſeeds of this plant are frequently ſtrung, and are worn as ornaments by the natives of thoſe countries, where the plants grow naturally: they are frequently brought to England from the Weſt-Indies, and are wrought into various forms, with ſhells and other hard ſeeds.

This plant is propagated by ſeeds, which muſt be ſown upon a good hot-bed in the ſpring; but as the ſeeds are very hard, ſo unleſs they are ſoaked in water twelve or fourteen hours before they are ſown, they frequently lie in the ground a whole year before they vegetate; but when ſoaked, the plants will appear in a fortnight after the ſeeds are ſown, if they are good, and the bed in a proper temperature of heat. When the plants are two inches high, they ſhould be each tranſplanted into a ſeparate pot, filled with light earth, and plunged into a hot-bed of tanners bark, where they ſhould be ſhaded from the ſun till they have taken new root; after which they muſt be treated in the ſame manner as other tender plants from the ſame countries, always keeping them in the bark-ſtove, for they are too tender to thrive in any other ſituation in England. This ſort will flower the ſecond year from ſeeds, and ſometimes ripens ſeeds here.

There are two other varieties of this plant, one with a white, and the other a yellow ſeed, but the plants do not differ from the other in leaf or ſtalk; but as theſe have not as yet flowered in England, I do not know how their flowers may differ.

The fourth ſort hath a perennial root and an annual ſtalk, which decays in the autumn. This riſes from two to three feet high, with ſlender herbaceous ſtalks, which are garniſhed with trifoliate hairy leaves, ſitting cloſe to the ſtalks; the ſmall leaves or lobes, are of the oval ſpear-ſhape, ending in acute points. The flowers come out from the ſide of the ſtalks, at the foot-ſtalk of the leaves; the naked part of the foot-ſtalk is about two inches long, and the ſpike of flowers is about the ſame length, and is recurved; the flowers are of a Pea-bloſſom kind, ſitting cloſe together. They are ſmall, and of a fine blue colour, coming out the beginning of June, and are ſometimes ſucceeded by ſeeds in England, which ripen in Auguſt.

This ſort grows naturally in North America, and is hardy enough to live in the open air in England. It may be propagared by ſeeds, or parting of the roots; the former is the beſt method, where good ſeeds can be obtained: theſe may be ſown on a bed of light earth in the ſpring, and if the ſeaſon ſhould prove dry, they muſt be frequently refreſhed with water, otherwiſe they will remain a long time in the ground before they vegetate: when the plants come up, they muſt be kept clean from weeds in the ſummer, and in the autumn when their ſtalks are decayed, if ſome rotten tanners bark is ſpread over the ſurface of the ground, it will protect the roots from being injured by the froſt. In the ſpring, the roots ſhould be tranſplanted to the places where they are deſiged to remain, which muſt be in a warm ſheltered ſituation, but not too much expoſed to the ſun, and in a light ſoil, where they will thrive and produce flowers annually. If this is propagated by parting of the roots, it ſhould be done in the ſpring, before the roots begin to ſhoot, which is the beſt ſeaſon for tranſplanting the plants: but theſe roots ſhould not be parted oftener than every third year, for if they are often removed they will not flower ſo ſtrong.

The fifth ſort hath a perennial root and a climbing ſtalk, which riſes near four feet high, garniſhed with woolly trifoliate leaves: the flowers come out in ſhort bunches from the ſide of the ſtalks; they are ſmall, of a yellow colour, and are ſucceeded by ſhort pods, which contain two roundiſh ſeeds in each. This flowers in June, and the ſeeds ripen in autumn. It grows naturally in America, but is too tender to live in the open air in England. This is propagated in the ſame manner, and requires the ſame treatment as the third ſort.

GLYCYRRHIZA. Lin. Gen. Plant. 788. Tourn. Inſt. R. H. 389. tab. 210. [ſo called of γλυκὺς, ſweet, and ῥίζα, *Gr.* a root, q. d. ſweet root: the ancients called it Scythian Root, becauſe the Scythians firſt brought it into uſe.] Liquorice; in French, *Regliſſe.*

The Characters are,

The flower hath a permanent tubulous empalement of one leaf, divided into two lips; the upper lip is cut into three parts, the middle one being broad and bifid, the under lip is ſingle. The flower hath four petals, is of the butterfly kind, having a long erect ſtandard, with *oblong wings, and a two-leaved keel which is acute. It hath ten ſtamina, nine joined and one ſtanding ſingle; they are longer than the keel, and terminated by roundiſh ſummits. In the bottom is ſituated a ſhort germen, ſupporting an awl-ſhaped ſtyle the length of the ſtamina, crowned by a riſing obtuſe ſtigma. The germen afterward becomes an oblong, or oval compreſſed pod with one cell, including two or three kidney-ſhaped ſeeds.*

This genus of plants is ranged in the third ſection of Linnæus's ſeventeenth claſs, intitled Diadelphia Decandria, which includes thoſe plants which have ten ſtamina joined in two bodies.

The SPECIES are,

1. GLYCYRRHIZA (*Glabra*) leguminibus glabris. Hort. Cliff. 490. *Liquorice with ſmooth pods.* Glycyrrhiza ſiliquoſa, vel Germanica. C. B. P. *Common Liquorice.*
2. GLYCYRRHIZA (*Echinata*) leguminibus echinatis. Prod. Leyd. 386. *Liquorice with prickly pods.* Glycyrrhiza capite echinato. C. B. P. *Rough-podded Liquorice.*
3. GLYCYRRHIZA (*Hirſuta*) leguminibus hirſutis. Prod. Leyd. 386. *Liquorice with hairy pods.* Glycyrrhiza Orientalis, ſiliquis hirſutiſſimis. Tourn. Cor. *Eaſtern Liquorice with hairy pods.*

The firſt ſort is that which is commonly cultivated in England for medicine; the other two kinds are preſerved in curious botanic gardens for variety, but their roots are not ſo full of juice as the firſt, nor is the juice ſo ſweet; though the ſecond ſort ſeems to be that which Dioſcorides has deſcribed and recommended, but I ſuppoſe the goodneſs of the firſt has occaſioned its being ſo generally cultivated in Europe.

The roots of this run very deep into the ground, and creep to a conſiderable diſtance, eſpecially where they are permitted to ſtand long unremoved; from theſe ariſe ſtrong herbaceous ſtalks, four or five feet high, garniſhed with winged leaves, compoſed of four or five pair of oval lobes, terminated by an odd one; the leaves and ſtalks are clammy, and of a dark green; the flowers come out in ſpikes from the wings of the ſtalks, ſtanding erect; they are of a pale blue colour, and are ſucceeded by ſhort compreſſed pods, each containing two or three kidney-ſhaped ſeeds. It flowers the latter end of July, but the ſeeds do not ripen in England.

This plant delights in a light ſandy ſoil, which ſhould be three feet deep at leaſt, for the goodneſs of Liquorice conſiſts in the length of the roots: the greateſt quantity of Liquorice which is propagated in England, is about Pontefract in Yorkſhire, and Godalmin in Surry; though of late years there hath been a great deal cultivated in the gardens near London: the ground in which you intend to plant Liquorice, ſhould be well dug and dunged the year before you plant it, that the dung may be perfectly rotted, and mixed with the earth, otherwiſe it will be apt to ſtop the roots from running down; and before you plant it, the ground ſhould be dug three ſpades deep, and laid very light; when your ground is thus well prepared, you ſhould furniſh yourſelf with freſh plants taken from the ſides or heads of the old roots, obſerving that they have a good bud or eye, otherwiſe they are ſubject to miſcarry; theſe plants ſhould be about ten inches long, and perfectly ſound.

The beſt ſeaſon for planting them is in the beginning or middle of March, which muſt be done in the following manner, viz. Firſt ſtrain a line croſs the ground in which you would plant them, then with a long dibble made on purpoſe, put in the ſhoot, ſo that the whole plant may be ſet ſtrait into the ground, with the head about an inch under the ſurface in a ſtrait line, about a foot aſunder, or more, in the rows, and two feet diſtance row from row; and after having finiſhed the whole ſpot of ground, you may ſow a thin crop of Onions, which being plants that do not root deep into the ground, nor ſpread much above, will do the Liquorice no damage the firſt year; for the Liquorice will not ſhoot very high the firſt ſeaſon, and the hoeing of the Onions will alſo keep the ground clear from weeds; but in doing of this you muſt be careful not to cut off the top ſhoots of the Liquorice plants when they appear above ground; which would greatly injure them; and alſo obſerve to cut up all the Onions which grow near the heads of the Liquorice; and after your Onions are pulled up, you ſhould carefully hoe and clean the ground from weeds; and in October, when the ſhoots of the Liquorice are decayed, you ſhould ſpread a little very rotten dung upon the ſurface of the ground, which will prevent the weeds from growing during the winter, and the rain will waſh the virtue of the dung into the ground, which will greatly improve the plants.

In the beginning of March following you ſhould ſlightly dig the ground between the rows of Liquorice, burying the remaining part of the dung; but in doing of this, you ſhould be very careful not to cut the roots. This ſtirring of the ground will not only preſerve it clean from weeds a long time, but alſo greatly ſtrengthen the plants.

The diſtance which I have allowed for planting theſe plants, will, I doubt not, by ſome, be thought too great; but in anſwer to that, I would only obſerve, that as the largeneſs of the roots is the chief advantage to the planter, ſo the only method to obtain this, is by giving them room; and beſides, this will give a greater liberty to ſtir and dreſs the ground, which is of great ſervice to Liquorice; and if the plantation deſigned were to be of an extraordinary bigneſs, I would adviſe the rows to be made at leaſt three feet diſtant, whereby it will be eaſy to ſtir the ground with a breaſt plough, which will greatly leſſen the expence of labour.

Theſe plants ſhould remain three years from the time of planting, when they will be fit to take up for uſe, which ſhould not be done until the ſtalks are perfectly decayed; for when it is taken up too ſoon, it is ſubject to ſhrink greatly, and loſe of its weight.

The ground near London being rich, increaſes the bulk of the root very faſt; but when it is taken up, it appears of a very dark colour, and not near ſo ſightly as that which grows upon a ſandy ſoil in an open country.

The ſecond ſort grows naturally in ſome parts of Italy, and in the Levant; the ſtalks and leaves of this are very like thoſe of the firſt, but the flowers are produced in ſhorter ſpikes, and the pods which ſucceed them are very ſhort, broad at their baſe, ending in acute points, and are armed with ſharp prickles. This flowers about the ſame time as the firſt, and in warm ſeaſons will perfect ſeeds in England.

The third ſort grows naturally in the Levant, from whence the ſeeds were ſent to the royal garden at Paris, by Dr. Tournefort. This hath much the appearance of the other two ſpecies, but the pods of it are hairy, and longer than thoſe of the other. Both theſe ſorts may be propagated in the ſame manner as the firſt, or from ſeeds, which may be ſown in the ſpring on a bed of light earth; but as neither of theſe are uſed, ſo they are ſeldom propagated unleſs for the ſake of variety.

GNAPHALIUM. Lin. Gen. Plant. 850. Elichryſum. Tourn. Inſt. R. H. 452. tab. 259. Goldylocks, or Eternal Flower; in French, *Immortelle.*

The CHARACTERS are,

It hath a compound flower, made up of hermaphrodite florets and female half florets, included in one ſcaly empalement; the hermaphrodite florets are tubulous, funnel-ſhaped, and cut into five parts at the brim, which are reflexed; theſe have five ſhort hairy ſtamina, terminated by cylindrical ſummits. In the center is ſituated a germen, ſupporting a ſlender ſtyle the length of the ſtamina, crowned by a bifid ſtigma; the germen afterward becomes a ſingle ſeed, which in ſome ſpecies is crowned with a hairy down, and in others a feathery down. The female flowers which are intermixed with theſe have no ſtamina, but a germen ſupporting a ſlender ſtyle, crowned by a bifid reflexed ſtigma. Theſe are in ſome ſpecies fruitful, and in others they are barren. The empalement of the flower is permanent and ſhining.

This genus of plants is ranged in the firſt ſection of Linnæus's nineteenth claſs, which includes thoſe plants which have hermaphrodite and female flowers incloſed in one common empalement, and are fruitful.

The Species are,

1. Gnaphalium (*Stæchas*) fruticoſum foliis linearibus, ramis virgatis, corymbo compoſito. Hort. Cliff. 401. *Goldylocks with a ſhrubby ſtalk garniſhed with very narrow leaves, and a compound corymbus of flowers.* Elichryſum ſeu ſtœchas citrina anguſtifolia. C. B. P. 264. *Caſſidony, or narrow-leaved Goldylocks.*

2. Gnaphalium (*Anguſtiſſimum*) foliis linearibus, caule fruticoſo ramoſo, corymbo compoſito. Hort. maximis, ſarmentis procumbentibus. Lin. Sp. Plant. 850. *Goldylocks with a ſimple ſtalk, large oval leaves at bottom, and trailing runners.* Gnaphalium plantaginis folio, Virginianum. Pluk. Alm. 171. *Virginia Goldylocks with a Plantain leaf.*

23. Gnaphalium (*Obtuſifolium*) herbaceum foliis lanceolatis, caule tomentoſo paniculato terminalibus glomeratis conicis. Lin. Sp. Plant. 851. *Goldylocks with ſpear-ſhaped leaves, a woolly ſtalk, terminated by a conical cluſter of flowers.* Elichryſum obtuſifolium, capitulis argenteis conglobatis. Hort. Elth. 130. *Blunt-leaved Goldylocks, with ſilvery heads growing in cluſters.*

24. Gnaphalium (*Spicatum*) foliis lanceolatis decurrentibus tomentoſis, floribus ſpicatis terminalibus lateralibuſque. *Goldylocks with ſpear-ſhaped, woolly, running leaves, and flowers growing in ſpikes at the ends and ſides of the ſtalks.* Elichryſum caule alato, floribus ſpicatis. Sloan. Cat. Jam. 125. *Goldylocks with a winged ſtalk and ſpiked flowers.*

The firſt ſort hath a ſhrubby ſtalk, which riſes about three feet high, branching out into long ſlender ſtalks irregularly; the lower branches are garniſhed with obtuſe leaves, two inches and a half long, and an eighth of an inch broad at the point, but thoſe upon the flower-ſtalks are very narrow, ending in acute points; the whole plant is very woolly: the flowers terminate the ſtalks in a compound corymbus; their empalements are of a ſilvery colour at firſt, and very neat, but afterward turn of a yellowiſh ſulphur colour. If theſe are gathered before the flowers are much opened, the heads will continue in beauty many years, eſpecially if they are kept from the air and duſt. The plants begin to flower in June, and there is a ſucceſſion of flowers all the ſummer, ſome of which will continue in beauty moſt part of the winter. This is generally ſuppoſed to be the true golden Caſſidony of the ſhops, but the ſecond ſort is uſually ſubſtituted for it in England.

It is propagated by ſlips or cuttings, which may be planted in June or July, in a bed of light earth, and covered with glaſſes, or ſhaded with mats, obſerving to refreſh them frequently with water, but it muſt not be given in large quantities; theſe cuttings will put out roots in ſix or eight weeks, then they ſhould be taken up and planted in pots filled with light earth, and placed in a ſhady ſituation till they have taken new root, when they may be removed to an open ſituation, and placed among other hardy exotics, till about the middle or end of October; at which time they ſhould be placed under a common frame, where they may be protected from froſt, but in mild weather they ſhould be expoſed to the open air. With this management in winter, the plants will be much ſtronger than thoſe which are kept in the green-houſe, where they generally draw too weak; for this ſort only wants to be ſheltered from hard froſt, being ſo hardy as in very mild winters to live abroad in warm borders near walls, with little ſhelter.

The ſecond ſort hath a ſhrubby ſtalk, which divides into many ſlender branches, covered with a white bark; theſe form a thick buſhy under ſhrub, and riſe near three feet, garniſhed with very narrow leaves, hoary on their under ſide, but green on their upper, placed without order on every ſide the ſtalks; the flowers are produced in a compound corymbus at the end of the branches; their heads are ſmall, and are of a yellow colour when fully blown; theſe are continued in ſucceſſion moſt part of ſummer. This grows naturally in France and Germany, and is hardy enough to live in the open air in England. It is propagated by ſlips or cuttings, which may be planted in a ſhady border during any of the ſummer months, and in the autumn they may be tranſplanted into the places where they are deſigned to remain. This ſhould have a dry undunged ſoil, in which it is rarely injured unleſs in the moſt ſevere froſt.

The third ſort is an annual plant, which grows naturally in Italy and Sicily; this hath an herbaceous ſtalk, which riſes little more than a foot high, garniſhed with acute indented leaves, which are hoary on their under ſide; the flowers ſtand upon long foot-ſtalks, which riſe far above the branches, each ſuſtaining one ſmall whitiſh flower. Theſe appear in July, and the ſeeds ripen in September. It is propagated by ſeeds, which ſhould be ſown in autumn upon a bed of light earth, where the plants are deſigned to remain; and when the plants come up in the ſpring, they ſhould be thinned where they are too cloſe, and kept clean from weeds, which is all the culture they require.

The fourth ſort is an annual plant with woolly leaves, which riſe with woolly ſtalks about eight inches high, garniſhed with oblong leaves which embrace the ſtalks with their baſe; the flowers grow in cloſe cluſters at the top, and from the ſide of their ſtalks, which are included in dry ſilvery empalements.

There is another ſpecies of this with narrower leaves, not quite ſo woolly; the ſtalks riſe higher, and are more branched; the flowers grow in cloſe bunches on the top of the ſtalks, and are of a pale yellow colour. Both theſe ſorts will come up better from the ſcattered ſeeds, than when they are ſown by art; but if the ſeeds are ſown, it muſt be ſoon after they are ripe, otherwiſe they will not ſucceed. The plants require no other care but to keep them clean from weeds, and thinned where they are too cloſe. They flower in July, and the ſeeds ripen in autumn.

The fifth ſort is an annual plant, which grows naturally in many parts of England, on places which are covered with water in the winter; this is a low branching plant, with ſilvery leaves and dark heads of flowers, but being of no uſe is not cultivated in gardens.

The ſixth ſort is alſo an annual plant with narrow leaves, which are hoary on their under ſide; the ſtalks grow erect about a foot high, and at every joint is produced a ſhort ſpike of white flowers, with dark-coloured empalements. This is found growing naturally in ſome parts of England, ſo is not often admitted into gardens. If the ſeeds of this ſort are permitted to ſcatter, the plants will come up in the ſpring with greater certainty than if ſown, and they will require little culture. Theſe flower in July, and the plants decay ſoon after they have ripened their ſeeds.

The ſeventh ſort grows naturally in the northern parts of England, upon the tops of hills and mountains, where the ſhoots which are ſent out from every ſide of the plant put out roots, whereby it is propagated in great plenty: the leaves of this grow cloſe to the ground, they are narrow at their baſe, but rounded at the end where they are broad; they are near an inch long, and hoary on their under ſide; the ſtalks are ſingle, and riſe about four inches high, terminated by a corymbus of flowers which is ſingle. This flowers in May and June.

There are two varieties of this, one with a purple and the other a variegated flower, which have riſen accidentally from ſeeds, but continue their difference in the gardens. They are eaſily propagated by offſets, which ſhould be planted in the autumn, in a ſhady ſituation, where they will require no other care but to keep them clean from weeds. This plant is called Pes Cati, or *Catsfoot.*

The eighth ſort grows naturally on the Alps. This is a low plant, with under leaves like the laſt mentioned; the ſtalks are ſingle, and riſe about ſix inches high, garniſhed with very ſmall acute leaves, and terminated by four or five oblong flowers, which in ſome plants are white, and in others of a purpliſh colour. They appear about the ſame time as the former ſort, and the plants may be propagated and treated in the ſame manner.

The ninth ſort grows naturally in Spain and Italy. This is a low plant with a ligneous ſtalk, which ſeldom riſes more than ſix inches high, garniſhed with very narrow leaves, white on their under ſide; the flowers are produced from the ſide of the ſtalks, each ſtanding upon a ſeparate foot-ſtalk; their empalements are ſcaly and long, ending in acute ſtiff points, and are of a purpliſh colour. This ſort flowers in July, but ſeldom perfects ſeeds in this country.

The tenth ſort is ſuppoſed to have been brought firſt from India to Portugal, where it has been long propagated for the beauty of its golden heads of flowers, which, if gathered before they are too open, will continue in beauty ſeveral years; ſo that in the winter ſeaſon they ornament their churches with theſe flowers, and many of them are annually brought to England, and ſold for ornaments to the ladies. Theſe plants have a ſhort ſhrubby ſtalk, ſeldom riſing more than three or four inches high, putting out many heads; the leaves are narrow and woolly on both ſides, and come out without order; the flower-ſtalks ariſe from theſe heads; they grow eight or ten inches high, are garniſhed all the way with narrow hoary leaves, and terminated by a compound corymbus of bright yellow flowers with large heads. Theſe begin to flower in May, and there is a ſucceſſion of them moſt part of ſummer. This is propagated by ſlipping off the heads during any of the ſummer months, and after ſtripping off the lower leaves, they ſhould be planted in a bed of light earth, covering them with hand-glaſſes, which muſt be ſhaded every day when the ſun is warm; and the cuttings muſt be ſupplied with water, which ſhould be often repeated, but not in too great quantities; when theſe are rooted they ſhould be planted in pots, and treated in the ſame manner as hath been directed for the firſt ſort. Theſe plants in mild winters will live abroad in a very warm border with little ſhelter, and the hardier they are treated, the greater number of flowers they will produce; for when they are drawn weak in a green-houſe, they never flower ſo ſtrong.

The eleventh ſort hath very woolly ſtalks and leaves, which are much longer than thoſe of the tenth; the ſtalks riſe a foot high, ſending out a few ſide branches; theſe are terminated by a compound corymbus of flowers, whoſe heads are ſmall, and of a gold colour, changing a little red as they fade. This is propagated by ſlips in the ſame manner as the laſt mentioned, but the plants will live in the open air, if they are planted on a dry ſoil.

The twelfth ſort grows naturally in North America, but has been long in the Engliſh gardens. This hath a creeping root, which ſpreads far in the ground, ſo as to become a troubleſome weed very often, unleſs it is kept within bounds; the ſtalks of this are woolly, riſing a foot and a half high, garniſhed with long leaves ending in acute points, which are placed alternate, and are woolly on their under ſide; the upper part of the ſtalk branches into two or three diviſions, each being terminated by a cloſe corymbus of flowers, with pretty large ſilvery empalements, which, if gathered and properly dried, will retain their beauty ſeveral years. This ſort will thrive in almoſt any ſoil or ſituation, and is eaſily propagated by its creeping roots. It flowers in June and July, and the ſtalks decay in autumn.

The thirteenth ſort grows naturally at the Cape of Good Hope. This is an annual plant, which ſends out many oblong blunt leaves near the root; the ſtalks riſe a foot and a half high, garniſhed with leaves placed alternate, which are broad at their baſe where they embrace the ſtalks, but end in acute points; they are woolly, and when handled, emit a very rank odour; the ſtalks are terminated by a corymbus of flowers, in large ſilvery empalements, which will retain their beauty ſeveral years.

The fourteenth ſort grows naturally at the Cape of Good Hope, and is an annual plant, very like the former ſort, but the leaves are of a yellowiſh green on their upper ſide, and woolly on their under; the ſtalks branch, and the heads of flowers are of a bright yellow colour, and theſe differences are permanent. Both theſe plants are propagated by ſeeds, which, if ſown in the autumn on a warm border, will more certainly ſucceed, than when they are ſown in the ſpring; or if the ſeeds are permitted to ſcatter, the plants will come up without care, and may be tranſplanted while they are young, to the places where they are deſigned to remain: when the plants have taken root, they will require no other care but to keep them clean from weeds. They flower in July, and the ſeeds ripen in autumn.

The fifteenth ſort grows in Africa, and alſo in North America, from both theſe countries I have received the ſeeds. It is an annual plant, with oblong leaves at the bottom, which are a little waved, and hoary on their under ſide. The ſtalks riſe about a foot high, and are garniſhed with acute-pointed leaves; from their baſe runs a border or wing along the ſtalk; the whole plant has a diſagreeable odour. The flowers grow in a corymbus on the top of the ſtalks, they are white, and appear in July. The ſeeds ripen in the autumn, which, if permitted to ſcatter, the plants will come up without care, as the two former ſorts.

The ſixteenth ſort riſes with a ſhrubby ſtalk three or four feet high, ſending out many branches from the lower part, garniſhed with narrow ſpear-ſhaped leaves, which half embrace the ſtalks with their baſe; they are of a dark green on their upper ſide, but are hoary on their under; the ſtalks are terminated by a compound corymbus of yellow flowers, whoſe heads are ſmall: theſe continue in ſucceſſion great part of the ſummer, but are rarely ſucceeded by ſeeds in England. It is eaſily propagated by cuttings in any of the ſummer months, which may be planted in a ſhady border, and duly watered. Theſe will take root in a month or five weeks, and may then be taken up and planted in pots, placing them in a ſhady ſituation till they have taken freſh root; then they may be removed to a ſheltered ſituation, and placed with other hardy green-houſe plants till autumn, when they muſt be carried into the green-houſe, where, during the winter ſeaſon, they ſhould have as much free air as poſſible in mild weather, for they only require protection from froſt, ſo they ſhould be treated in the ſame manner as other hardy green-houſe plants.

The ſeventeenth ſort is an annual plant, which grows naturally in France, Italy, and Spain. This hath a woolly herbaceous ſtalk, which riſes ſix or eight inches high, garniſhed with obtuſe, ſpear-ſhaped, woolly leaves. The flowers are produced in ſhort ſpikes from the ſide, and at the top of the ſtalks; they are of a ſilvery colour, and appear in June and July. The ſeeds ripen in autumn, which, if permitted to ſcatter, the plants will come up without care, and require no other culture, but to keep them clean from weeds.

The eighteenth ſort grows naturally at the Cape of Good Hope; this riſes with a ſlender ſhrubby ſtalk, which ſends out many lateral branches below; theſe are garniſhed with very narrow leaves, which are hoary on their under ſide. The flowers are produced in a compound corymbus at the end of the branches; they are at their firſt appearance of a pale red colour, but afterward change to a gold colour; the empalements of this ſort are ſmall, and dry like the other ſpecies of this genus. This ſort is propagated by cuttings, in the ſame manner as the ſixteenth, and the plants require the ſame treatment.

The nineteenth ſort grows naturally in Egypt and Paleſtine. This is a perennial plant, whoſe under leaves ſpread near the ground; they are woolly on their under ſide; the ſtalks riſe about ſix inches high; the leaves upon theſe are ſpear-ſhaped, ending in acute points; the ſtalks and leaves are woolly, and the ſtalk is terminated by a large corymbus of flowers ſitting very cloſe; theſe are of a fine ſoft red colour, ſo make a pretty appearance in the month of June, when they are in beauty.

This ſort is propagated by offſets in the ſame manner as the ſeventh and eighth ſorts, but this doth not produce them in plenty, ſo is very uncommon in the Engliſh gardens at preſent: it requires a drier ſoil than the ſeventh, and a warmer ſituation, but not too much expoſed to the mid-day ſun, ſo ſhould be planted to a ſouth-eaſt aſpect.

The twentieth ſort grows naturally at the Cape of Good Hope, but has been long preſerved in many curious gardens in Europe; the ſtalk riſes three or four feet high, ſending out ſeveral long irregular branches, which are terminated by a compound corymbus of flowers. The heads of this ſort are compoſed of leaves, which are much longer than thoſe of any other ſort; the heads of the flowers are of a bright ſilver colour. This is propagated by cuttings, which ſhould be planted in the ſame manner as hath been directed for the tenth ſort, and the plants ſhould alſo be treated in the ſame way.

The twenty-firſt ſort was raiſed from ſeeds in the Chelſea garden, which came from the Cape of Good Hope; the lower leaves of this are oblong and blunt. The ſtalks are ſhrubby, and divide into many irregular branches, which riſe about three feet high; theſe are garniſhed with oblong blunt-pointed leaves, hoary on their under ſide, but of a dark green above; from the baſe of the leaves runs a border along the ſtalk, like a wing, of the ſame conſiſtence with the leaves, ſo is what the former botaniſts termed a winged ſtalk, but Dr. Linnæus calls it a running leaf. The ſtalks are terminated by a compound corymbus of flowers, which are very cloſely joined together, and are of a bright gold colour, but the flowers are ſmall, and change to a darker colour as they fade; there is a ſucceſſion of theſe flowers moſt part of the ſummer, and the early flowers are frequently ſucceeded by ſeeds in England. This ſort may be propagated by ſlips, or cuttings, in the ſame manner as the tenth, and the plants may be treated in the ſame manner as is directed for that. It is engraven in the 131ſt plate of the figures of plants.

The twenty-ſecond ſort grows naturally in North America, from whence the ſeeds have been brought to England; this is a perennial plant, whoſe lower leaves are large and oval; from the main ſtalk there come out runners, which take root in the ground, and have young plants at their extremity. The ſtalks are ſingle, and garniſhed with narrower woolly leaves, placed alternate. The flowers are produced at the top of the ſtalks in a corymbus, they are of a white colour and ſmall. They appear in June and July, and ſometimes are ſucceeded by ſeeds, but the plants propagate ſo faſt by offſets, that the ſeeds are little regarded; this will thrive in the open air, if planted in a dry ſoil and a warm ſituation.

The twenty-third ſort grows naturally in North America; it is an annual plant, with woolly obtuſe leaves. The ſtalks are ſingle, and riſe about nine inches high. The flowers grow in ſpikes from the ſide of the ſtalks; they are of a dirty white colour, ſo make no great appearance. If the ſeeds of this are permitted to ſcatter, the plants will riſe without trouble, and only require to be kept clean from weeds.

The twenty-fourth ſort grows naturally in Jamaica, and other of the hot parts of America; this riſes with a ſhrubby ſtalk about two feet high, garniſhed with leaves about the ſize and ſhape of thoſe of Sage, but woolly on their under ſide, and much veined; from the baſe of each leaf runs a border along the ſtalk. The flowers are produced in ſpikes from the ſide, and at the end of the ſtalk; theſe are long, and cloſely joined in the ſpike. It flowers in July and Auguſt, but never perfects ſeeds in England.

It is propagated by ſeeds, which ſhould be ſown on a hot-bed in pots, becauſe the plants do not often riſe the ſame year; therefore when it ſo happens, the pots ſhould be placed in the ſtove in winter, and the following ſpring put upon a freſh hot-bed to bring up the plants; when theſe appear they muſt be planted into pots, and kept conſtantly in the hot-bed, otherwiſe they will not thrive in England.

GNAPHALODES. See MICROPUS.

GNIDIA.

The CHARACTERS are,

It hath a funnel-ſhaped empalement of one coloured leaf, with a long tube divided into four ſegments; the flower hath four plain petals ſhorter than the empalement inſerted to it, and eight briſtly erect ſtamina, terminated by ſimple ſummits, and an oval germen ſupporting a ſlender ſtyle on the ſide inſerted with the ſtamina, crowned by a ſtinging ſtigma; the germen afterward becomes one oval oblique-pointed ſeed, incloſed in the empalement.

This genus of plants is ranged in the firſt order of Linnæus's eighth claſs, intitled Octandria Monogynia, the flower having eight ſtamina and one ſtyle.

We have but one SPECIES of this genus, viz.

1. GNIDIA (*Pinifolia*) foliis ſparſis lineari-ſubulatis, floribus verticillatis, aggregatis terminalibus. Lin. Sp. 512. *Gnidia with linear awl-ſhaped leaves, and flowers placed cloſely in whorls terminating the branches.* Rapunculus foliis nervoſis linearibus, floribus argenteis non galeatis. Burm. Afr. 112.

This plant grows naturally in Æthiopia. It hath a low ſhrubby ſtalk, which riſes three or four feet high, ſending out a few ſide branches, garniſhed with narrow, oblong, acute-pointed leaves, which are green on their upper ſide, but pale on their under, with a ſtrong longitudinal nerve, reſembling the leaves of Roſemary: the flowers come out almoſt in whorls from between the leaves on the extremity of the branches, ſtanding on ſhort foot-ſtalks; they have long ſlender tubes, and are divided at the top into four ſegments which ſpread horizontally, having eight very ſhort ſtamina in the bottom of the tube, and an oval germen with a ſlender ſtyle faſtened to the ſide of the ſtamina; the germen is afterward ſucceeded by one oval-pointed ſeed. There are two varieties of this, one with a white, and the other hath a blue flower.

This is uſually propagated here by cuttings, which if carefully planted during the ſummer months, in pots filled with light earth, plunged into a very moderate hot-bed, covering the pots cloſely with either bell or hand-glaſſes to exclude the air, being careful to ſhade the glaſſes daily, the cuttings will put out roots in ſix weeks, when they ſhould be gradually inured to the open air. In winter the plants ſhould be placed in a dry airy glaſs-caſe, where they may enjoy free air in mild weather, but protected from froſt and damp air.

GOMPHRENA. Lin. Gen. Plant. 279. Amaranthoides. Tourn. Inſt. R. H. 654. tab. 420.

The CHARACTERS are,

The flower hath a large three-leaved empalement, which is coloured and permanent. The petal is erect, and cut into five parts at the top; it hath a cylindrical tubulous empalement the length of the petal, cut into five ſmall parts at the brim, which ſpread open; it hath five ſtamina ſcarcely diſcernible, ſituated in the brim of the nectarium, terminated by ſummits, ſhut up in the mouth of the nectarium. In the center is ſituated an oval-pointed germen, with two ſmall ſtyles, crowned with ſingle ſtigma the length of the ſtamina. The germen afterward becomes one large roundiſh ſeed, incloſed in a thin cruſted capſule with one cell.

This genus of plants is ranged in the ſecond ſection of Linnæus's fifth claſs, intitled Pentandria Digynia, which includes the plants whoſe flowers have five ſtamina and two ſtyles.

The SPECIES are,

1. GOMPHRENA (*Globoſa*) caule erecto, foliis ovato-lanceolatis, capitulis ſolitariis, pedunculis diphyllis. Hort. Cliff. 86. *Gomphrena with an erect ſtalk, oval ſpear-ſhaped leaves, ſingle heads, and foot-ſtalks having two leaves.* Amaranthoides Lychnidis folio, capitulis purpureis. Tourn. Inſt. R. H. 654. *Globe Amaranthus with purple heads.*
2. GOMPHRENA (*Serrata*) caule erecto, ſpicâ interruptâ. Prod. Leyd. 419. *Gomphrena with an erect ſtalk, and an interrupted ſpike of flowers.*
3. GOMPHRENA (*Perennis*) foliis lanceolatis, capitulis diphyllis, floſculis perianthio proprio diſtinctis. Lin. Sp. Plant. 224. *Gomphrena with ſpear-ſhaped leaves, two leaves to the heads, and each floret having its proper empalement.* Amaranthoides perenne, floribus ſtramineis radiatis. Hort. Elth. 24. tab. 20. *Perennial Globe Amaranthus with radiated ſtraw-coloured flowers.*

The firſt ſort grows naturally in India, from whence the ſeeds were brought to Europe, and the plants have been many years cultivated in all the curious gardens: it is an annual plant, which riſes with an upright branching ſtalk about two feet high, garniſhed with ſpear-ſhaped leaves placed oppoſite. The branches alſo come out oppoſite, and the foot-ſtalks of the flowers, which are long and naked, having two ſhort leaves, cloſe under each head of flowers ariſes from the forks of the branches. The heads at their firſt appearance are globular, but as they increaſe in ſize become oval; theſe are compoſed of dry ſcaly leaves or petals, placed imbricatim like the ſcales of fiſh; under each of theſe is ſituated a tubulous flower, which juſt peeps out of the covering, but theſe are not much regarded by the generality of people; for the ſcaly empalement which covers them is ſo beautiful, and theſe if gathered before they are too much faded, will retain their beauty ſeveral years. After the flowers are paſt, the germen, which is ſituated in the bottom of each, becomes a large oval ſeed, incloſed in a chaffy covering, which ripens late in autumn, and the plants decay ſoon after.

There are two varieties of this ſort, one with fine bright purple heads, the other hath white or ſilvery heads, and theſe never alter from ſeeds, ſo that they are permanent varieties, though in other reſpects they do not differ: there is alſo one with mixed colours, but whether this aroſe accidentally from the ſeeds of either of the former, I cannot determine, for this variety continues from ſeeds, and the other two I have cultivated more than thirty years, and have never found either of them vary.

There are alſo two varieties of theſe which grow naturally in the Weſt-Indies, one with purple, and the other with white heads, which are much ſmaller and rounder than thoſe before-mentioned. The plants grow much larger, and ſpread more into branches, and they are later before they flower, ſo that in cold ſeaſons the ſeeds rarely ripen in England; theſe are called Bachelors Buttons by the inhabitants of America, but whether they are ſpecifically different from the others, I cannot with certainty determine.

The ſecond ſort hath much ſlenderer ſtalks than the firſt, which grow taller, and are irregular. The leaves are ſmaller, but of the ſame ſhape. The flowers grow in ſpikes at the end of the branches, which are broken, or divided into three or four parts with ſpaces between them. The ſpikes are ſmall, and of a pale purple colour. The ſeeds of this ſort were ſent me by the late Dr. Houſtoun from Campeachy.

The third ſort hath ſlender upright ſtalks, which are garniſhed with ſpear-ſhaped leaves placed oppoſite; they are hairy, and ſit cloſe to the ſtalks, which alſo are hairy, and terminated by ſmall heads of flowers, which ſpread open from each other, ſo as that the empalement appear diſtinct; theſe are of a pale ſtraw colour, and appear in July. The ſeeds ſometimes will ripen in England, but the plants will live two or three years, if they are preſerved in a ſtove.

The two ſorts with large heads of flowers which are firſt mentioned, one with purple, and the other which is ſilver-coloured, are very ornamental plants in gardens, and are now very commonly cultivated in the Engliſh gardens. In Portugal, and other warm countries, they are cultivated to adorn their churches in the winter; for if theſe are gathered when they are fully grown, and dried in the ſhade, they will retain their beauty a long time, eſpecially if they are not expoſed to the air; theſe plants are annual, ſo are only propagated by ſeeds, which ſhould be ſown on a good hot-bed the beginning of March; but if the ſeeds are not taken out of their chaffy covering, it will be proper to ſoak them in water for twelve hours before they are ſown, which will greatly facilitate their growing. When the plants are come up an inch high, they ſhould be tranſplanted on a freſh hot-bed, at about four inches diſtance, obſerving to ſhade them till they have taken root; then they ſhould have freſh air admitted to them every day, in proportion to the warmth of the ſeaſon; they will alſo require to be frequently refreſhed with water. In about a month's time, if the hot-bed is of a proper warmth, the plants will have grown ſo large, as to nearly meet, therefore they will require more room, otherwiſe they will draw up weak; then a freſh hot-bed ſhould be prepared, into which there ſhould be a ſufficient number of three farthing pots plunged, filled with light rich earth, and when the bed is in a proper temperature of warmth, the plants ſhould be carefully taken up with balls of earth to their roots, and each planted into a ſeparate pot, obſerving to ſhade them till they have taken new root, afterward they muſt be treated in the ſame manner as other tender exotic plants. When the plants have filled theſe pots with their roots, they ſhould be ſhaken out of the pots, and their roots on the outſide of the ball of earth muſt be carefully pared off; then they ſhould be put into pots a ſize larger, and when there is conveniency of a deep frame, to plunge the pots into another gentle hot-bed, it will bring the plants early to flower, and cauſe them to grow much larger than thoſe which are placed abroad. In July the plants ſhould be inured gradually to bear the open air, into which they may be removed about the middle of that month, and intermixed with other annual plants to adorn the pleaſure-garden; but it will be proper to keep a plant or two of each ſort in ſhelter for ſeeds, becauſe when the autumn proves cold or wet, thoſe plants which are expoſed abroad, ſeldom produce good ſeeds.

GOOSEBERRY. See GROSSULARIA.

GORTERIA.

The CHARACTERS are,

The empalement of the flower is ſtiff, ſcaly, ending in briſtly ſpines; the flower is compoſed of hermaphrodite florets in the diſk, and female in the rays or border; the hermaphrodite florets are funnel-ſhaped, five-pointed, having five ſhort ſtamina terminated by cylindrical ſummits, with a hairy germen ſupporting a ſlender ſtyle, crowned by a bifid ſtigma; the germen afterward becomes one roundiſh ſeed, ſurrounded by fine hairs. The female florets are tongue-ſhaped, have no ſtyle or ſtigma, and are barren.

This genus of plants is ranged in the third ſection of Linnæus's nineteenth claſs, intitled Syngeneſia Polygamia fruſtranea, the flowers being compoſed of hermaphrodite florets in the diſk which are fruitful, and female florets in the border, having neither ſtyle or ſtigma, ſo are barren.

The SPECIES are,

1. GORTERIA (*Ringens*) ſcapis unifloris, foliis lanceolatis pinnatifidis, caule depreſſo. Amœn. Acad. 6. p. 86. *Gorteria with one flower on each foot-ſtalk, ſpear-ſhaped, wing-pointed leaves, and a depreſſed ſtalk.* Arctotis ramis decumbentibus, foliis lineari-lanceolatis rigidis ſubtus argenteis. Ed. prior.
2. GORTERIA (*Fruticoſa*) foliis lanceolatis integris dentato-ſpinoſis ſubtus tomentoſis, caule fruticoſo. Lin. Sp. 1284. *Gorteria with entire ſpear-ſhaped leaves, whoſe indentures end in ſpines, woolly on their under ſide, and a ſhrubby ſtalk.* Carthamus Africanus fruteſcens, folio ilicis, flore aureo. Walth. Hort. 13. tab. 7.

The firſt ſort grows naturally at the Cape of Good Hope; it is a low ſpreading plant, with ligneous ſtalks ſix or eight inches long trailing on the ground, having two or three ſide branches, each terminating in a cloſe head of leaves, which are narrow, green on their upper ſide, but ſilvery on their under, cut into three or five ſegments at their ends. The foot-ſtalks of the flowers ariſe from the heads, and are ſix inches long, naked, ſupporting one large Orange-coloured flower at the top, compoſed of ſeveral hermaphrodite florets in the diſk, which are fruitful; but the female half florets on the border are tongue-ſhaped, ſpreading open, each having a dark mark toward their baſe, with a white ſpot intermixed. The flowers appear in May and June, but are ſeldom ſucceeded by ſeeds in England.

This plant is eaſily propagated by cuttings planted in a ſhady border during any of the ſummer months, and the plants muſt be afterward treated as is directed for ARCTOTIS.

The ſecond ſort grows naturally at the Cape of Good Hope. This riſes with a ſhrubby ſlender ſtalk three feet high, ſending out a few weak branches, garniſhed with oblong leaves ſitting cloſe to the branches; they are ſmooth on their upper ſide, woolly underneath, and indented on their edges, each indenture ending with a weak ſpine. The flowers terminate the ſtalks, having leafy empalements ending with ſpines; the flowers are yellow, and appear in the ſummer months, but are not ſucceeded by ſeeds in England.

It is propagated by planting of the ſmall heads at the end of the branches, in June or July, which muſt be cloſely covered with either bell or hand-glaſſes, or they will not ſucceed, and ſhould be carefully ſcreened from the ſun. When theſe are well rooted, they ſhould be put each into a ſmall pot, and in winter ſhould be placed in an airy glaſs-caſe ſecure from damps.

GORZ. See Ulex.

GOSSYPIUM. Lin. Gen. Plant. 755. Xylon. Tourn. Inſt. R. H. 101. tab. 27. Cotton.

The Characters are,

The flower has a double empalement; the outer is large, of one leaf, and cut half way into three ſegments; the inner is cup-ſhaped, of one leaf, cut into five obtuſe ſegments at the top. It hath five plain heart-ſhaped petals, which join at their baſe, and ſpread open. It hath a great number of ſtamina, which are joined at bottom in a column, but are looſe above, and inſerted into the petals; theſe are terminated by kidney-ſhaped ſummits. It hath a round germen, ſupporting four ſtyles, joined in the column, and are the ſame length of the ſtamina, crowned by four thick ſtigmas. The germen afterward becomes a roundiſh capſule, ending in a point, having four cells, which are filled with oval ſeeds, wrapped up in down.

This genus of plants is ranged in the third ſection of Linnæus's ſixteenth claſs, intitled Monodelphia Polyandria, which includes the plants whoſe flowers have many ſtamina, which are joined together with the ſtyles in one column or body.

The Species are,

1. Gossypium (*Herbaceum*) foliis quinquelobis, caule herbaceo lævi. Hort. Upſal. 203. *Cotton with leaves having five lobes, and a ſmooth herbaceous ſtalk.* Goſſypium. Camer. Epit. 203. *The common herbaceous Cotton.*
2. Gossypium (*Barbadenſe*) foliis trilobis integerrimis ſubtus biglandulosis. Hort. Upſal. 205. *Cotton-tree with entire leaves, having three lobes with three glands under their ſide.* Goſſypium fruteſcens annuum, folio trilobo Barbadenſe. Pluk. Alm. 172. tab. 188. *Shrubby annual Barbadoes Cotton, with leaves having three lobes.*
3. Gossypium (*Arboreum*) foliis palmatis, lobis lanceolatis, caule fruticoſo. Lin. Sp. Plant. 693. *Cotton with hand-ſhaped leaves, having five ſpear-ſhaped lobes, and a ſhrubby ſtalk.* Xylon arboreum, flore flavo. Tourn. Inſt. R. H. 101. *Tree Cotton with a yellow flower.*
4. Gossypium (*Hirſutum*) foliis trilobis & quinquelobiſque acutis, caule ramoſo hirſuto. *Cotton with leaves having three and five lobes, ending in acute points, and a hairy branching ſtalk.* Xylon Americanum præſtantiſſimum, ſemine vireſcente. Lign. Tourn. Inſt. R. H. 101. *Fineſt American Cotton with a green ſeed.*

The firſt ſort is the common Levant Cotton, which is cultivated in ſeveral Iſlands of the Archipelago, as alſo in Malta, Sicily, and the kingdom of Naples; it is ſown in tilled ground in the ſpring of the year, and is ripe in about four months after, when it is cut down in harveſt as Corn is in England; the plants always periſh ſoon after the ſeeds are ripe: this plant grows about two feet high, with an herbaceous ſtalk, garniſhed with ſmooth leaves divided into five lobes. The ſtalks ſend out a few weak branches upward, which are garniſhed with leaves of the ſame form but ſmaller. The flowers are produced near the extremity of the branches, at the foot-ſtalks of the leaves; theſe have two large empalements, the outer is cut into three parts, and the inner into five. The petals of the flower are of a pale yellow colour, inclining to white; theſe are ſucceeded by oval capſules, which open in four parts, having four cells, which are filled with ſeeds wrapped up in down, which is the Cotton.

The ſecond ſort grows naturally in ſeveral iſlands of the Weſt-Indies; this riſes with a ſhrubby ſmooth ſtalk four or five feet high, ſending out a few ſide branches, which are garniſhed with ſmooth leaves, divided into three lobes. The flowers are produced toward the end of the branches, which are ſhaped like thoſe of the former ſort, but are larger, and of a deeper yellow colour. The pods are larger, and the ſeeds are black.

The third ſort hath a perennial ſhrubby ſtalk, which riſes ſix or eight feet high, and divides into many ſmooth branches, garniſhed with hand-ſhaped leaves, having four or five lobes. The flowers are produced toward the end of the branches; theſe are larger than thoſe of the two former ſorts, and are of a deep yellow colour. The pods of this ſort are larger than thoſe of the former.

The fourth ſort is a native of the Eaſt and Weſt-Indies, from whence the ſeeds have been brought to Europe; this is alſo an annual plant, which periſhes ſoon after the ſeeds are ripe. It riſes to the height of three feet or more, and ſends out many lateral branches, which extend to a great diſtance, where they are allowed room to grow; theſe are hairy, and garniſhed with leaves, having in ſome three, and others five acute-pointed lobes, with ſhort hairy down on their ſurface. The flowers are produced from the ſide, and at the end of the branches; theſe are large, of a dirty ſulphur colour, each petal having a large purple ſpot at the baſe, and are ſucceeded by oval pods, which open into four cells, which are filled with oblong green ſeeds wrapped up in a ſoft down. Where the plants have room to ſpread, their branches will produce four or five pods of Cotton upon each, ſo that from a ſingle plant, thirty or more pods may be produced; and each of theſe are as large as middling Apples, ſo there will be a much greater produce from this than from any other ſort, and the ſtaple is much finer; therefore it is well worth the attention of the inhabitants of the Britiſh colonies in America to cultivate and improve this ſort, ſince it will ſucceed in Carolina, where it it has been cultivated for ſome years; and might be a commodity worthy of encouragement by the public, could they contrive a proper gin to ſeparate the Cotton from the ſeeds, to which this ſort adheres much cloſer than any of the other ſorts, the Cotton from this ſhrub being preferable to any other yet known.

All theſe ſorts are very tender plants, therefore will not thrive in the open air in England, but they are frequently ſown in curious gardens for variety: the firſt and fourth ſorts will produce ripe ſeeds in England, if their ſeeds are ſown early in the ſpring, upon a good hot-bed; and when the plants are come up, planted each into ſeparate pots, and plunged into a hot-bed of tanners bark to bring them forward; and when they are grown too tall to remain under the frames, removed into the tan-bed in the ſtove, and ſhifted into larger pots, when their roots have filled the other; with this management I have had their flowers appear in July, and toward the end of September the ſeeds have been perfectly ripe, and the pods as large as thoſe produced in the Eaſt and Weſt-Indies; but if the plants are not brought forward early in the ſpring, it will be late in the ſummer before the flowers will appear, and there will be no hopes of the pods coming to perfection.

The Shrub-cotton will riſe from the ſeeds very eaſily, if they are ſown upon a good hot-bed; and when they are ſown early in the ſpring, and brought forward in the ſame manner as hath been directed for the former ſorts, the plants will grow to be five or ſix feet high the ſame ſummer; but it is difficult to preſerve the plants through the winter, unleſs they are hardened gradually in Auguſt during the continuance of the warm weather; for when they are forced on at that time, they will be ſo tender, as to render them incapable of reſiſting the leaſt injury. The plants of this ſort muſt be placed in the bark-ſtove in autumn, and kept in the firſt claſs of heat, otherwiſe they will not live through the winter in England.

GRAFTING is the taking a ſhoot from one tree, and inſerting it into another, in ſuch a manner, as that both may unite cloſely, and become one tree; this is called by the ancient writers in huſbandry and gardening, inciſion, to diſtinguiſh it from inoculating, or budding, which they call inſerere oculos.

The uſe of grafting is to propagate any curious ſorts of fruits, ſo as to be certain of the kinds, which cannot be done by any other method; for as all the good fruits have been accidentally obtained from ſeeds, ſo the ſeeds of theſe, when ſown, will many of them degenerate, and produce ſuch fruit as are not worth cultivating; but when ſhoots are taken from ſuch trees as produce good fruit, theſe will never alter from their kind, whatever be the ſtock, or tree, on which they are grafted; for though the grafts receive their nouriſhment from the ſtocks, yet their varieties are never altered by them, but continue to produce the ſame kind of fruit as the tree from which they were taken; the only alteration is, that when the ſtocks on which they are grafted do not grow ſo faſt, and afford a ſufficient ſupply of nouriſhment to the grafts, they will not make near ſo great progreſs as they otherwiſe would do, nor will the fruit they produce be ſo fair, and ſometimes not ſo well flavoured.

Theſe ſhoots are termed cions, or graffs; in the choice of theſe the following directions ſhould be carefully obſerved. 1ſt, That they are ſhoots of the former year, for when they are older, they never ſucceed well. 2dly, Always to take them from healthy fruitful trees, for if the trees are ſickly from whence they are taken, the grafts very often partake ſo much of the diſtemper as rarely to get the better of it, at leaſt for ſome years; and when they are taken from young luxuriant trees, whoſe veſſels are generally large, they will continue to produce luxuriant ſhoots, and are ſeldom ſo fruitful as thoſe which are taken from fruitful trees, whoſe ſhoots are more compact, and the joints cloſer together; at leaſt it will be a great number of years before the luxuriant grafts begin to produce fruit, if they are managed with the greateſt ſkill. 3dly, You ſhould prefer thoſe grafts which are taken from the lateral, or horizontal branches, to thoſe from the ſtrong perpendicular ſhoots, for the reaſons before given.

Theſe grafts, or cions, ſhould be cut off from the trees before their buds begin to ſwell, which is generally three weeks or a month before the ſeaſon for grafting; therefore, when they are cut off, they ſhould be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a ſmall joint of the former year's wood is cut off with the cion, it will preſerve it the better, and when they are grafted, this may be cut off; for at the ſame time the cions muſt be cut to a proper length before they are inſerted in the ſtocks; but, till then, the ſhoots ſhould remain their full length, as they were taken from the tree, which will preſerve them better from ſhrinking; if theſe cions are to be carried to a conſiderable diſtance, it will be proper to put their ends into a lump of clay, and to wrap them up in moſs, which will preſerve them freſh for a month, or longer; but theſe ſhould be cut off earlier from the trees than thoſe which are to be grafted near the place where the trees are growing.

Having given directions for the cions and grafts, we next come to that of the ſtock, which is a term applied to the trees intended for grafting; theſe are either ſuch old trees as are already growing in the places where they are to remain, whoſe fruit is intended to be changed, or young trees, which have been raiſed in a nurſery for a ſupply to the garden; in the former caſe there is no other choice, but that of the branches, which ſhould be ſuch as are young, healthy, well ſituated, and have a ſmooth bark; if theſe trees are growing againſt walls, or eſpaliers, it will be proper to graft ſix, eight, or ten branches, according to the ſize of the trees, by which they will be much ſooner furniſhed with branches again, than when a leſs number of cions are put in; but in ſtandard-trees, four, or at moſt ſix cions will be ſufficient.

In the choice of young ſtocks for grafting, you ſhould always prefer ſuch as have been raiſed from the ſeed, and that have been once or twice tranſplanted. Next to theſe, are thoſe ſtocks which have been raiſed from cuttings, or layers, but thoſe which are ſuckers from the roots of other trees ſhould always be rejected, for theſe are never ſo well rooted as the others, and conſtantly put out a great number of ſuckers from their roots, whereby the borders and walks of the garden will be always peſtered with them during the ſummer ſeaſon, which is not only unſightly, but they alſo take off part of the nouriſhment from the trees.

If theſe ſtocks have been allowed a proper diſtance in the nurſery where they have grown, the wood will be better ripened, and more compact than thoſe which have grown cloſe and have been there drawn up to a greater height; the wood of theſe will be ſoft, and their veſſels large, ſo that the cions grafted into them will ſhoot very ſtrong, but they will be leſs diſpoſed to produce fruit than the other; and when trees acquire an ill habit at firſt, it will be very difficult to reclaim them afterward.

Having directed the choice of cions and ſtocks, we come next to the operation, in order to which you muſt be provided with the following tools.

1. A neat ſmall hand-ſaw to cut off the heads of large ſtocks.
2. A good ſtrong knife with a thick back, to make clefts in the ſtocks.
3. A ſharp penknife to cut the grafts.
4. A grafting chiſſel and a ſmall mallet.
5. Baſs ſtrings, or woollen yarn, to tie the grafts with, and ſuch other inſtruments and materials as you ſhould find neceſſary, according to the manner of grafting you are to perform.
6. A quantity of clay, which ſhould be prepared a month before it is uſed, and kept turned and mixed, like mortar every other day, which is to be made after the following manner:

Get a quantity of ſtrong fat loam (in proportion to the quantity of trees intended to be grafted, then take ſome new ſtone-horſe dung, and break it in amongſt the loam, and if you cut a little ſtraw, or hay, very ſmall, and mix amongſt it, the loam will hold together the better; and if there be a quantity of ſalt added, it will prevent the clay from dividing in dry weather; theſe muſt be well ſtirred together, putting water to them after the manner of making mortar; it ſhould be hollowed like a diſh, and filled with water, and kept every other day ſtirred; but it ought to be remembered, that it ſhould not be expoſed to the froſt, or drying winds, and the oftener it is ſtirred and wrought the better.

Of late years ſome perſons have made uſe of another compoſition for grafting, which they have found to anſwer the intention of keeping out the air, better than the clay before deſcribed. This is compoſed of turpentine, bees-wax, and roſin, melted together, which, when of a proper conſiſtence, may be put on the ſtock round the graft, in the ſame manner as the clay is uſually applied; and though it be not above a quarter of an inch thick, yet it will keep out the air more effectually than the clay; and as cold will harden this, there is no danger of its being hurt by froſt, which is very apt to cauſe the clay to cleave, and ſometimes fall off; and when the heat of ſummer comes on, this mixture will melt, and fall off without any trouble. In uſing of this, there ſhould be a tin, or copper-pot, with conveniency under it to keep a very gentle fire with ſmall-coal, otherwiſe the cold will ſoon condenſe the mixture; but you muſt be careful not to apply it too hot, leſt you injure the graft. A perſon who is a little accuſtomed to this compoſition, will apply it very faſt, and it is much eaſier for him than clay, eſpecially if the ſeaſon ſhould prove cold.

There are ſeveral ways of grafting, the principal of which are four:

1. Grafting in the rind, called alſo ſhoulder-grafting, which is only proper for large trees; this is called crown-grafting, becauſe the grafts are ſet in form of a circle, or crown, and is generally performed

formed about the latter end of March, or the beginning of April.

2. Cleft-grafting, which is alſo called ſtock, or ſlit-grafting; this is proper for trees or ſtocks of a leſſer ſize, from an inch, to two inches or more diameter; this grafting is to be performed in the months of February and March, and ſupplies the failure of the eſcutcheon way, which is practiſed in June, July, and Auguſt.

3. Whip-grafting, which is alſo called tongue-grafting; this is proper for ſmall ſtocks of an inch, half an inch, or leſs, diameter; this is the moſt effectual way of any, and which is moſt in uſe.

4. Grafting by approach, or ablactation; this is to be performed when the ſtock you would graft on, and the tree from which you take your graft, ſtand ſo near together, that they may be joined; this is to be performed in the month of April, and is alſo called inarching, and is chiefly uſed for Jaſmines, Oranges, and other tender exotic trees.

We come next to the manner of performing the ſeveral ways of grafting.

The firſt method, which is termed rind, or ſhoulder-grafting, is ſeldom practiſed but on large trees, where either the head, or the large branches, are cut off horizontally, and two or four cions put in, according to the ſize of the branch, or ſtem; in doing of this, the cions are cut flat on one ſide, with a ſhoulder to reſt upon the crown of the ſtock; then the rind of the ſtock muſt be raiſed up, to admit the cion between the wood and the bark of the ſtock, which muſt be inſerted about two inches, ſo as the ſhoulder of the cion may meet, and cloſely join the crown of the ſtock; and after the number of cions are inſerted, the whole crown of the ſtock ſhould be well clayed over, leaving two eyes of the cions uncovered therewith, which will be ſufficient for ſhooting; this method of grafting, was much more in practice formerly than at preſent; the diſcontinuance of it was occaſioned by the ill ſucceſs it was attended with; for as theſe cions were placed between the rind of the ſtock and the wood, ſo they are frequently blown out by ſtrong winds, after they had made large ſhoots, which has ſometimes happened after five or ſix years growth; ſo that whenever this method is practiſed, there ſhould be ſome ſtakes faſtened to ſupport the cions, until they have almoſt covered the ſtock.

The next method is termed cleft, or ſtock-grafting; this is practiſed upon ſtocks, or trees, of a ſmaller ſize, and may be uſed with ſucceſs, where the rind of the ſtock is not too thick, whereby the inner bark of the cion will be prevented joining to that of the ſtock; this may be performed on ſtocks, or branches, which are more than one inch diameter; in the doing of this, the head of the ſtock, or branch, muſt be cut off with a ſlope, and a ſlit made the contrary way, in the top of the ſlope, deep enough to receive the cion, which ſhould be cut ſloping like a wedge, ſo as to fit the ſlit made in the ſtock, being careful to leave that ſide of the wedge, which is to be placed outward, much thicker than the other; and in putting the cion into the ſlit of the ſtock, there muſt be great care taken to join the rind of the cion to that of the ſtock; for if theſe do not unite, the grafts will not ſucceed: when this method of grafting is uſed to ſtocks which are not ſtrong, it will be proper to make a ligature of baſs, to prevent the ſlit of the ſtock from opening; then the whole ſhould be clayed over, to prevent the air from penetrating the ſlit, ſo as to deſtroy the grafts, only leaving two eyes of the cions above the clay for ſhooting.

The third method is termed whip, or tongue-grafting, which is the moſt commonly practiſed of any by the nurſerymen near London, eſpecially for ſmall ſtocks, becauſe the cions much ſooner cover the ſtocks in this method than in any other.

This is performed by cutting off the head of the ſtocks ſloping; then there muſt be a notch made in the ſlope toward the upper part downward, a little more than half an inch deep, to receive the cion, which muſt be cut with a ſlope upward, and a ſlit made in this ſlope like a tongue, which tongue muſt be inſerted into the ſlit made in the ſlope of the ſtock, and the cion muſt be placed on one ſide of the ſtock, ſo as that the two rinds of both cion and ſtock may be equal, and join together exactly; then there ſhould be a ligature of baſs to faſten the cion, ſo as that it may not be eaſily diſplaced; and afterward clay it over, as in the former methods.

The fourth ſort of grafting is termed inarching, grafting by approach, or ablactation. This is only to be performed when the ſtocks, which are deſigned to be grafted, and the tree from which the graft is to be taken, ſtand ſo near together, or may be brought ſo near together, as that their branches may be united; this method of grafting is commonly practiſed on tender exotic plants, and ſome other ſorts which do not ſucceed in any of the other methods.

In performing this operation, a part of the ſtock, or branch, muſt be ſlit off about two inches in length, obſerving always to make choice of a ſmooth part of the ſtock; then a ſmall notch ſhould be made in this ſlit of the ſtock downward, in the ſame manner as hath been directed for whip-grafting; then the branch of the tree deſigned to be inarched, ſhould have a part ſlit off in like manner as the ſtock, and a ſlit made upward in this, ſo as to leave a tongue; which tongue ſhould be inſerted into the ſlit of the ſtock, obſerving to join their rinds equally, that they may unite well together; then make a ligature of baſs, to keep them exactly in their ſituation, and afterward clay this part of the ſtock over well, to keep out the air; in this method of grafting, the cion is not ſeparated from the tree, until it is firmly united with the ſtock, nor is the head of the ſtock, or branch, which is grafted, cut off till this time, and only half the wood pared off with a ſlope, about three inches in length, and the ſame of the cion, or graft.

This method of grafting is not performed ſo early in the ſeaſon as thoſe of the other, it being done in the month of April, when the ſap is flowing, at which time the cion and ſtock will join together, and unite much ſooner than at any other ſeaſon.

The Walnut, Fig, and Mulberry, will take by this method of grafting, but neither of theſe will ſucceed in any of the other methods; there are alſo ſeveral ſorts of Evergreens, which may be propagated by this method of grafting; but all the trees which are grafted in this way are weaker, and never grow to the ſize of thoſe which are grafted in the other methods; therefore this is rarely practiſed, but on ſuch ſorts of trees as will not take by the other methods.

The next thing which is neceſſary to be known, by thoſe who would practiſe this art, is, what trees will take and thrive by being grafted upon each other; and here there have been no ſure directions given by any of the writers on this ſubject, for there will be found great miſtakes in all their books, in relation to this matter; but as it would ſwell this article too great, if all the ſorts of trees were to be here enumerated, which will take upon each other by grafting, I ſhall only mention ſuch general directions, as, if attended to, will be ſufficient to inſtruct perſons, ſo as they may ſucceed.

All ſuch trees as are of the ſame genus, i. e. which will agree in their flower and fruit, will take upon each other: for inſtance, all the Nut-bearing trees may be ſafely grafted on each other, as may all the Plumb-bearing trees, under which head I reckon not only the ſeveral ſorts of Plumbs, but alſo the Almond, Peach, Nectarine, Apricot, &c. which agree exactly in their general characters, by which they are diſtinguiſhed from all other trees; but as many of theſe are very ſubject to emit large quantities of gum from the parts of the trees as are deeply cut and wounded, ſo the tender trees of this kind, viz. Peaches and Nectarines, which are moſt ſubject to this, it is found to be the ſureſt method to bud or inoculate theſe ſorts of fruits, for which ſee Inoculation.

Then all ſuch trees as bear cones will do well upon each other, though they may differ in one being evergreen, and the other ſhedding its leaves in winter; as is obſervbale in the Cedar of Libanus, and the Larch-tree, which are found to ſucceed upon each other very well; but theſe muſt be grafted by approach, for they abound with a great quantity of reſin which is apt to evaporate from the graft, if ſeparated from the tree before it is joined with the ſtock, whereby they are often deſtroyed; as alſo the Laurel on the Cherry, or the Cherry on the Laurel. All the maſt-bearing trees will alſo take upon each other, and thoſe which have a tender ſoft wood will do well if grafted in the common way; but thoſe that are of a more firm contexture, and are ſlow growers, ſhould be grafted by approach.

By ſtrictly obſerving this rule, we ſhall ſeldom miſcarry, provided the operation be rightly performed, and at a proper ſeaſon, unleſs the weather ſhould prove very bad, as it ſometimes happens, whereby whole quarters of fruit-trees miſcarry; and it is by this method that many kinds of exotic trees are not only propagated, but alſo rendered hardy enough to endure the cold of our climate in the open air; for, being grafted upon ſtocks of the ſame ſort which are hardy, the grafts are rendered more capable to endure the cold, as hath been experienced by moſt of our valuable fruits now in England, which were formerly tranſplanted here from more ſoutherly climates, and were at firſt too impatient of our cold to ſucceed well abroad; but have been, by budding or grafting upon more hardy trees, rendered capable of reſiſting our ſevereſt cold.

And theſe different graftings ſeem to have been greatly in uſe among the ancients, though they were certainly miſtaken in the ſeveral ſorts of fruits which they mention to have ſucceeded upon each other; as the Fig upon the Mulberry, the Plumb upon the Cheſtnut, with many others of the like kind; moſt of which I have already tried, and find they will not ſucceed; therefore what has been advanced on this head by the ancients, is not founded on experience; or at leaſt they did not mean the ſame plants, which at preſent are called by thoſe names; though I cannot help thinking we are apt to pay too much deference to the writings of the ancients, in ſuppoſing them ſeldom to be miſtaken, or to aſſert a falſhood; whereas, if their works are carefully examined, it will be found, that they have often copied from each other's writings, without making experiments to prove the truth of their aſſertions: and it is well known, that the ranging of plants before Cæſalpinus's time (which is about 170 years ſince) was, by their outward appearance, or from the ſuppoſed virtues of them, which method is now juſtly exploded; and it hath been obſerved, from many repeated trials, that however plants may reſemble each other in the ſhape and make of their leaves, manner of ſhooting, &c. unleſs they agree in their fruit, and their other diſtinctive characters, they will not grow upon each other, though performed with ever ſo much art.

GRAMEN. Tourn. Inſt. R. H. 516. tab. 297. Raii Meth. Plant. 171. Graſs; in French, *Chien-dent*.

To enumerate all the ſpecies of Graſs which are found growing naturally in England, would ſwell this article greatly beyond the deſign of the work; therefore I ſhall only take notice of a few ſpecies, which are either uſed in medicine, or cultivated for fodder; for there is ſcarce a paſture in this country, where at leaſt twenty different ſpecies are not to be found intermixed, and in moſt of them more than twice that number. Theſe were, by the former writers on botany, all included under the common denomination of Gramen, but were divided into different ſections. Mr. Ray has ranged them in the following order, Gramen Triticum, i. e. Wheat-graſs. Gramen Secalinum, i. e. Rye-graſs. Gramen Loliaceum, i. e. Darnel-graſs. Gramen Paniceum, i. e. Panic-graſs. Gramen Phalaroides, i. e. Canary-graſs. Gramen Alopecuroides, i. e. Fox-tail-graſs. Gramen Typhinum, i. e. Cat's-tail-graſs. Gramen Echinatum, i. e. Hedgehog-graſs. Gramen Criſtatum, i. e. Creſted-graſs. Gramen Avenacium, i. e. Oat-graſs. Gramen Dactylon, i. e. Cock's-foot-graſs. Gramen Arundinaceum, i. e. Reed-graſs. Gramen Milleacem, i. e. Millet-graſs. And under each of theſe ſections there are many ſpecies. And there are many others, which, by older writers, were included under this general title, ſome of which have no relation to this claſs; but there are others which are near nearly allied to it, as the Cyperus and Cypreſs Graſſes, &c. Theſe Dr. Linnæus has divided into genera; but by this method of claſſing them, he has ſeparated them to a great diſtance from each other; for all thoſe whoſe flowers have three ſtamina, are ranged in his third claſs; and others which have male and female flowers, are removed to his twenty-firſt claſs. However, it would have been much better to have kept them together, as Dr. Van Royen has done in the Prodromus of the Leyden garden, under one general title to the claſs of Graminea.

As the ſeveral genera under which the different ſpecies of Graſs are ranged, have different characters by which they are diſtinguiſhed, ſo it would be to little purpoſe to give them all in this work; and as there are no general characteriſtics by which the whole claſs can be known, ſo I ſhall not trouble the reader with any of them here, but proceed to enumerate a few of the ſpecies.

1. GRAMEN ſpicâ triticeâ repens vulgare, caninum dictum. Raii Syn. 2. p. 247. *Common creeping Graſs with a ſpike like Wheat, called Dog-graſs.* Triticum calycibus ſublatis trifloris acuminatis. Lin. Sp. Plant. *Wheat with an awl-ſhaped pointed empalement including three flowers, commonly called Couch, Couch-graſs, or Quick-graſs.*
2. GRAMEN loliaceum, anguſtiore folio & ſpicâ. C. B. P. *Darnel-graſs, with a narrower leaf and ſpike.* Lolium ſpicâ muticâ. Lin. Sp. Plant. 83. *Darnel with a chaffy ſpike, commonly called Ray, or Rye-graſs.*
3. GRAMEN pratenſe, paniculatum majus anguſtiore folio. C. B. P. 2. *Meadow-graſs with larger panicles and a narrower leaf.* Poa paniculâ diffuſa, ſpiculis quadrifloris pubeſcentibus, culmo erecto tereti. Flor. Suec. 77. *Poa with a diffuſed panicle, the ſmaller ſpikes having four hairy flowers, and a taper erect ſtraw.*
4. GRAMEN pratenſe, paniculatum majus, latiore folio. C. B. P. 2. *Meadow-graſs with a larger panicle and broader leaf.* Poa paniculâ diffuſâ ſpiculis trifloris glabris, culmo erecto tereti. Flor. Suec. 76. *Poa with a diffuſed panicle, ſmall ſpikes with three flowers, and an upright ſtraw.*
5. GRAMEN avenacium pratenſe elatius paniculâ flaveſcente, locuſtis parvis. Raii Syn. 407. *Taller Meadow Oat-graſs, with a yellowiſh panicle and ſmall huſks.* Avena paniculâ laxâ, calycibus trifloris brevibus, floſculis omnibus ariſtatis. Prod. Leyd. 66. *Oat-graſs with a looſe panicle, three flowers in each empalement, which is ſhort, and all the flowers having awns.*
6. GRAMEN ſecalinum. Ger. Emac. lib. 1. cap. 22. n. 4. *Tall Meadow Rye graſs.*
7. GRAMEN tremulum maximum. C. B. P. 2. *Greateſt Quaking-graſs, or Cowquakes.* Briza ſpiculis cordatis, floſculis ſeptendecim. Hort. Cliff. 23. *Briza with heart-ſhaped little ſpikes, and ſeventeen flowers in each.*

The firſt ſort of Graſs is that which is directed to be uſed in medicine; the roots of this are chiefly uſed, and are accounted aperitive and diuretic, opening obſtructions of the reins and bladder, provoking urine, and are of ſervice againſt the gravel and ſtone. The juice of the leaves and ſtalks was greatly eſteemed by Dr. Boerhaave, who generally preſcribed this in all caſes where he ſuppoſed there were any obſtructions in the bile conduit.

This hath a creeping root, which ſpreads far in the ground, and is a very troubleſome weed in gardens and arable land; for every ſmall piece of the root will grow and multiply exceedingly, ſo it is very difficult to extirpate where it once gets poſſeſſion: in gardens, the common method of deſtroying it is, to fork out the roots as often as the blades appear above ground; where this is two or three times carefully repeated, it may be totally rooted out; but when the ſurface of the ground is very full of the roots of this Graſs, the ſhorteſt way of deſtroying it, is to trench the ground two ſpits and a ſhovelling deep, turning all the couch into the bottom, where it will rot, and never ſhoot up; but this can only be practiſed, where there is a ſufficient depth of ſoil; for in ſhallow ground the roots cannot be buried ſo deep, as to lie below the depth to which they naturally ſhoot.

Where the roots of this Graſs get poſſeſſion in arable fields, it is very difficult to root out again; the uſual method is by laying the land fallow in ſummer, and frequently harrowing it well over to draw out the roots: where this is carefully practiſed, the ground may be ſo well cleaned in one ſummer, as that the roots cannot much injure the crop which may be ſown upon it; but ſuch land ſhould be cropped with Beans, Peas, or ſuch things as require the horſe-hoeing culture; for where the land can be frequently ſtirred and harrowed afterward, it will be of great ſervice in cleaning it from the roots of this Graſs and other bad weeds. The blade of this Graſs is ſo rough, that cattle will not feed upon it.

The ſecond ſort is frequently cultivated, eſpecially in ſtrong cold land, upon which this Graſs will ſucceed better than any other ſpecies, and is an earlier feed in the ſpring; but this is a very coarſe Graſs, and unleſs it is cut very early for hay, it becomes hard and wiery in the ſtalks, ſo that few cattle care to eat it; for this ſpecies has but few leaves, running all to ſtalk, ſo is uſually called Bents, and in ſome counties Bennet; when this graſs is fed, it will be proper to mow off the Bents in the beginning of June, otherwiſe they will dry upon the ground, and have the appearance of a ſtubble field all the latter part of ſummer; ſo that it will not only be very diſagreeable to the ſight, but alſo be troubleſome to the cattle that feed on it, by tickling their noſtrils; ſo that the want of better paſture only, will force them to eat of the young Graſs which ſprings up between theſe Bents, for thoſe they will not touch; therefore thoſe who ſuppoſe that theſe are eaten in ſcarcity of feed by the cattle, are greatly miſtaken; for I have many years cloſely attended to this, and have always found theſe Bents remaining on the ground untouched, till the froſt, rain, and winds, deſtroy it in winter; and, by permitting theſe to ſtand, the after-growth of the Graſs is greatly retarded, and the beautiful verdure is loſt for three or four months; ſo that it is good huſbandry to mow them before they grow too dry, and rake them off the ground: if theſe are then made into the hay, it will ſerve for cart-horſes or cows feed in winter, and will pay the expence of mowing it.

There is another ſpecies of this Graſs called Red Darnel, which is of a worſe nature than the firſt, the ſtalks growing hard much ſooner, and having narrower leaves. This is very common in moſt paſture grounds, for as it comes early to flower, ſo the ſeeds are generally ripe before the hay is cut, and from the falling ſeeds the ground is ſupplied with plenty of this ſort; therefore thoſe who are deſirous to keep their paſtures as clear from this Graſs as poſſible, ſhould always mow it before the ſeeds are ripe.

This Graſs is uſually ſown with Clover, upon ſuch lands as are deſigned to be ploughed again in a few years, and the common method is to ſow it with Spring Corn; but from many repeated trials, I have always found, that by ſowing theſe ſeeds in Auguſt, when there has happened a few ſhowers to bring up the Graſs, that the crop has anſwered much better than any which has been ſown in the common way; for the Graſs has often been ſo rank, as to afford a good feed the ſame autumn; and the following ſpring there has been a ton and a half of hay per acre mowed very early in the ſeaſon, and this has been upon cold ſour land; ſo that I am convinced of that being the beſt ſeaſon for ſowing theſe Graſſes, though it will be very difficult to perſuade thoſe perſons to alter their practice, who have been long wedded to old cuſtoms. The quantity of ſeeds which I allow to an acre is about two buſhels, and eight pounds of the common Clover, which, together, will make as good plants upon the ground as can be deſired; but this is not to be practiſed upon ſuch lands where the beauty of the verdure is principally regarded, therefore is fit for thoſe who have only profit in view.

The third and fourth ſorts are the two beſt ſpecies of Graſs for paſtures, ſo that if the ſeeds of theſe were carefully collected and ſown ſeparately without any other mixture of Graſs-ſeeds, they would not only afford a greater quantity of feed on the ſame ſpace of land, but the Graſs would alſo be better, the hay ſweeter, and the verdure more laſting than of any other ſorts; but there requires ſome attention to the ſaving of theſe ſeeds pure without mixture. I have tried to ſave the ſeeds of ſeveral ſpecies of Graſs ſeparately, in order to determine their qualities, but have found it very difficult to keep them diſtinct in gardens where the ſeeds of other ſorts of Graſs have been ſcattered: the only method in which I could ſucceed, was by ſowing each ſpecies in a diſtinct pot, and when the plants came up, to weed out all the other kinds of Graſs which came up in the pots; by this means I preſerved a great variety of the graſſy tribe ſeveral years, but not having ground enough to propagate the moſt uſeful ſpecies in any quantity, I was obliged to abandon the purſuit: but I muſt recommend this to perſons of leiſure and ſkill who have a ſufficient quantity of land for the purpoſe, to carry this project into execution, which may be of ſingular benefit to the public; for we have an inſtance of the advantage which the inhabitants of the Netherlands have made, by ſaving the ſeeds of the White Clover, or Honeyſuckle Trefoil, which is a plant common to moſt of the Engliſh paſtures; yet few perſons in this country ever gave themſelves the trouble to collect the ſeeds from the fields for ſowing, but have purchaſed vaſt quantities of this ſeed annually, at a conſiderable price from Flanders, where the peaſants have been ſo induſtrious, as to collect the ſeeds and ſow great quantities of land with it, with a view of ſale to this country only. This is not an inconſiderable article in huſbandry, but deſerves the attention of all thoſe, who, by choice or otherwiſe, are engaged in the buſineſs of agriculture; for one acre of land will produce as much ſeeds of this ſpecies of Trefoil, as will ſell for 12 l. where it is well planted and ſaved from the ſpring crop; and if the Graſs-ſeeds before-mentioned were ſeparately ſown, and carefully weeded from all other ſpecies, and permitted to ſtand till their ſeeds were ripe, it might be of equal advantage with the other, eſpecially now, when every gentleman is endeavouring to improve the verdure near their habitations.

The fifth and ſixth ſorts are alſo very good Graſſes for paſtures, and have perennial roots, ſo are the next beſt ſorts for ſowing to thoſe before-mentioned, which, in my opinion, deſerve the preference to all the other; but as it will be difficult to ſave a ſufficient quantity of ſeeds of thoſe alone, to ſupply the demand which may be for their ſeeds; ſo theſe two ſpecies may be admitted in aid of the other, as they are very leafy kinds of Graſs, and their ſtalks do not become ſtiff and harſh like many other ſpecies, but with proper care may be made very fine; and, if duly rolled, their roots will mat and form a very cloſe ſward, therefore theſe ſhould be included in the number of ſown Graſſes.

The ſeventh ſort is mentioned for the ſake of variety, and not for uſe; this hath an annual root, which ſends up many broad hairy leaves, between which ariſe ſlender ſtiff ſtalks from a foot to near two two feet high, dividing upward into a large looſe panicle, garniſhed with heart-ſhaped ſmall ſpikes, each having about ſeventeen ſmall floſcules or florets; theſe, after the flowers are paſt, have a ſingle ſeed ſucceeding them; the heads hang by ſlender long foot-ſtalks, which are moved by every wind, ſo that they generally appear ſhaking, from whence it had the title of Quaking Graſs. There are four ſpecies of this Graſs, two of them grow naturally in England; and theſe Graſſes coming to head in May, occaſioned the following

Engliſh proverb, *May come ſhe early come ſhe late, makes the cow quake.* The large ſort here mentioned, grows naturally in the ſouth of France and Italy, and is only preſerved in ſome Engliſh gardens for the ſake of variety.

If the ſeeds of this ſort are ſown in the autumn, or permitted to ſcatter when ripe, the plants will come up ſtronger, and flower much earlier, than when they are ſown in the ſpring, ſo good ſeeds may always be expected from them, which can ſeldom be attained from the ſpring plants in England; and as two or three plants of this ſort will be full enough in a garden for variety, ſo theſe ſhould be allowed to ſpread; for where they grow at a diſtance from each other, the roots will ſend out a great number of ſtalks, which will be ſtronger, and produce much larger panicles than thoſe which are too near together.

The Cock's-foot Graſs, Capon's-tail Graſs, and Millet Graſſes are too coarſe to deſerve attention in England, though ſome of their ſpecies are very uſeful in the warm parts of America, where there is a great ſcarcity of finer Graſs; and ſome of theſe are much better adapted to thoſe warm countries, than any of our European Graſſes, for many of them lie flat on the ground, and emit roots from their joints, ſo are well prepared for heat; their ſtalks are large and juicy, ſo will live in heat where few of the European Graſſes can be made to thrive.

The land on which Graſs-ſeed is intended to be ſown, ſhould be well ploughed, and cleared from the roots of noxious weeds, ſuch as Couch-graſs, Fern, Ruſhes, Heath, Gorſe, Broom, Reſt-harrow, &c. which, if left in the ground, will ſoon get the better of the Graſs, and over-run the land. Therefore in ſuch places where either of theſe weeds abound, it will be a good method to plough up the ſurface in April, and let it lie ſome time to dry; then harrow the roots into ſmall heaps, and burn them. The aſhes ſo produced, when ſpread on the land, will be a good manure for it. The method of burning the roots is particularly directed under the article LAND, which ſee: but where Couch-graſs, Fern, or Reſt-harrow is in plenty, whoſe roots run far under ground, the land muſt be ploughed two or three times pretty deep in dry weather, and the roots carefully harrowed off after each ploughing, which is the moſt ſure method to deſtroy them. Where the land is very low, and of a ſtiff clayey nature, which holds water in winter, it will be of ſingular ſervice to make ſome under-ground drains to carry off the wet; which, if detained too long on the ground, will render the Graſs ſour. The method of making theſe drains is preſcribed under the article LAND, which ſee.

Before the ſeed is ſown, the ſurface of the ground ſhould be made level and fine, otherwiſe the ſeed will be buried unequal. When the ſeed is ſown, it muſt be gently harrowed in, and the ground rolled with a wooden roller, which will make the ſurface even, and prevent the ſeeds being blown in patches. When the Graſs comes up, if there ſhould be any bare ſpots, where the ſeed has not grown, they may be ſown again, and the ground rolled, which will fix the ſeeds; and the firſt kindly ſhowers will bring up the Graſs, and make it very thick.

Where the land is deſigned to continue in paſture, it ſhould be ſown with the beſt ſorts of Graſs-ſeeds, and white Dutch Clover, or what is commonly called Honeyſuckle Graſs in many parts of England, but there is a great difficulty of procuring hay-ſeeds which are good; for in all the good paſtures near London, which abound with the beſt ſorts of Graſs, the hay is commonly cut before the ſeeds of the Graſs are ripe; ſo that thoſe ſeeds which are procured from the ſtables where the horſes are fed with the beſt ſort of hay, are little more than chaff, or at beſt are only ſuch as are of the early kinds of Graſs, with a great quantity of Plantain and other weeds: which has diſcouraged many gentlemen from ſowing them, nor has any one attempted to ſave theſe ſeeds properly; and as it requires longer time, and more attention, to ſave a quantity of ſeeds of the purer ſort of Graſs than the generality of people care to beſtow, ſo I would recommend the ſetting ſome of thoſe upland paſtures, which are cleaneſt from weeds, and have the ſweeteſt herbage aſide, to ſtand for ſeeds; and although by ſo doing the hay will be leſs valuable, yet from the ſale of the ſeeds, it may anſwer better to the poſſeſſor, than to mow it merely for the hay; for any gentleman who has regard to the beauty of his land, had better give ſix times the price for ſuch ſeeds, as is uſually paid for the ordinary ſeeds, ſince the firſt expence of ſeeds is not to be put in competition with the beauty and advantage of having ſuch as are good; for when the land is brought to a good ſward (which may be done in one year, where it is properly prepared and ſown with good ſeeds) it may be kept in good order, and by good management improved annually, and will continue ſo, as long as proper care is taken of it. I know ſome land which was ſown in the method hereafter directed above forty years ago, which are now as good paſtures as any I have ſeen, and may be always continued ſo.

Theſe grounds abounded with many bad weeds, ſo they had a winter and ſummer's fallow, in which time they were five times ploughed and ten times harrowed in order to deſtroy the weeds, and make the ſurface of the ground fine; in Auguſt they were ſown with the beſt Graſs-ſeeds as could be procured, three buſhels of this, and nine pounds of the white Dutch Clover-ſeeds were allowed to each acre; as there happened rains ſoon after the ſeeds were ſown, ſo the Graſs came up well; but among it were a great number of weeds, which were drawn up and carried off the ground, and in the beginning of October the fields were rolled with a Barley roller; in the ſpring the fields were again weeded, and afterward rolled, and that ſummer there was more than two tons of hay per acre mowed off the land; and by conſtant weeding twice a year, ſweeping it with a buſh harrow, rolling and dreſſing of the land, the Graſs has been greatly improved ſince, and is now as good paſture as any in England: and ſince I have laid down great quantities of land in the ſame manner, and with equal ſucceſs; therefore from many years experience can recommend it, as the ſureſt method of having good paſtures.

But I know the generality of farmers will object to the firſt loſs of their crop, and alſo to the after expence of weeding, rolling, &c. as too great for common practice: however, I am well ſatisfied from experience, that whoever will be at the expence, will find their account in it; for the crops of hay will be ſo much better, and the after paſture alſo, that it will more than pay the expence, as from many exact accounts, which have been kept of the whole, is ſufficiently demonſtrated, and the verdure of theſe paſtures is charming to all thoſe who have any taſte of natural beauties.

The proper management of paſture land is the leaſt underſtood of any part of agriculture; the farmers never have attended to this, being more inclined to the plough, though the profits attending that have not of late years been ſo great as to encourage them in that part of huſbandry; but theſe people never think of laying down land for paſture, to continue longer than three years, at the end of which time they plough it up again, to ſow it with grain.

There is a ſort of ſtriped Graſs which is preſerved in many gardens for the beauty of its variegated leaves, which continue freſh the greateſt part of the ſummer. This ſort is eaſily propagated by parting the roots, either in ſpring or autumn, for every offſet will increaſe to be a large root in one year's time. It will grow on any ſoil or in any ſituation, therefore may be planted in any abject part of the garden, where it will thrive, and afford an agreeable variety. This ſort is by many perſons called Ribband-graſs, from the ſtripes of white and green, which run the whole length of the blade, like the ſtripes in ſome ribbands.

For the further management of Graſs in fields, ſee PASTURE and MEADOW; and for that in gardens, ſee GRASS.

GRASS. The Engliſh Graſs is of ſo good a quality for walks or Graſs-plats, that if they be kept in good order, they have that exquiſite beauty that they cannot come up to in France, and ſeveral other countries. But green walks and green plats are, for the moſt part, not made by ſowing the Graſs-ſeed, but by laying turfs; and, indeed, the turfs from a fine common or down, are much preferable to ſown Graſs.

In ſowing a fine green plat, there is a difficulty in getting good ſeed; it ought not to be ſuch as is taken out of the hay-loft without diſtinction; for that ſeed ſhooting too high and making large ſtalks, the lower part will be naked and bare; and although it be mowed ever ſo often, it will never make handſome Graſs; but, on the contrary, will come to nothing but tufts of weeds and Quick-graſs, very little better than that of the common fields.

If walks or plats be made by ſowing, the beſt way is to procure the ſeed from thoſe paſtures where the Graſs is naturally fine and clear, or elſe the trouble of keeping it from ſpiry and benty Graſs will be very great, and it will ſcarce ever look handſome.

In order to ſow Graſs-ſeed, the ground muſt be firſt dug or broken up with a ſpade; and when it has been dreſſed and laid even, it muſt be very finely raked over, and all the clods and ſtones taken off, and covered over an inch thick with good mould, to facilitate the growth of the ſeed; this being done, the ſeed is to be ſown pretty thick, that it may come up cloſe and ſhort; and it muſt be raked over again to bury and cover the ſeed, that if the weather ſhould happen to be windy, it may not be blown away.

As to the ſeaſon of ſowing Graſs, the middle or latter end of Auguſt is a good time, becauſe the ſeed naturally requires nothing but moiſture to make it grow: if be not ſown till the latter end of February, or the beginning of March, if the weather proves dry, it will not ſo ſoon make the walks or quarters green. It is alſo beſt to ſow it in a mild day, and inclining to rain; for that, by ſinking down the ſeed in the earth, will cauſe it to ſhoot the ſooner. But where Graſs is ſown in gardens, either for lawns or walks, there ſhould always be a good quantity of the White Trefoil or Dutch Clover ſown with it, for this will make a fine turf much ſooner than any other ſown Graſs, and will continue a better verdure than any of the Graſs tribe.

After the ſeed is well come up, and the Graſs is very thick and of a beautiful green, it will require a conſtant care to keep it in order: this conſiſts in mowing the Graſs often, for the oftener it is mowed, the thicker and handſomer it grows; it muſt alſo be rolled with a cylinder or roller of wood, to level it as much as poſſible.

If Graſs be neglected, it will run into Quick-graſs and weeds; and if it does ſo, there is no way to recover it, but either by ſowing it, or laying it over again, and that once in every two years; but if the ground be well cleared from the roots of ſtrong weeds, and the turf be taken from a fine level common, it will continue handſome for ſeveral years, provided it be well kept.

In order to keep Graſs-plats or walks handſome and in good order, in autumn you may ſow ſome freſh ſeed over any places that are not well filled, or where the Graſs is dead, to renew and furniſh them again; but there is nothing which improves Graſs ſo much as conſtant rolling and polling it, to deſtroy wormcaſts, and thereby the turf is rendered fine.

It is a general practice when turf is laid in gardens, to cover the ſurface of the ground under the turf, either with ſand or very poor earth; the deſign of this is to keep the Graſs fine, by preventing its growing too rank. This is proper enough for very rich ground, but is not ſo for ſuch land as is but middling or poor; for when this is practiſed in ſuch places, the Graſs will ſoon wear out, and decay in patches.

When turf is taken from a common or down, there ſhould be regard had to the cleanneſs of it, and not to take ſuch as is full of weeds: for it will be a very tedious piece of work, to weed them out after the turf is laid; and unleſs this is done, the Graſs will never appear handſome.

Where turf is deſigned to remain for years without renewing, there ſhould be dreſſing laid upon it every other year, either of very rotten dung, aſhes, or, where it can be eaſily procured, very rotten tan, is a good dreſſing for Graſs; but theſe dreſſings ſhould be laid on early in winter, that the rain may waſh them into the ground, before the drought of the ſpring comes on, otherwiſe they will occaſion the Graſs to burn when the warmth of ſummer begins. Where Graſs is ſo dreſſed, and kept well rolled and mowed, it may be kept very beautiful for many years; but where it is not dreſſed or fed with ſheep, it will rarely continue handſome more than eight or ten years.

GRATIOLA. Lin. Gen. Plant. 27. Raii Meth. Plant. 90. Digitalis. Tourn. Inſt. R. H. 165. Hedge Hyſſop.

The CHARACTERS are,

The flower hath a permanent empalement, which is cut into five parts; it hath one petal of the grinning kind, with a tube longer than the empalement, cut at the top into four ſmall ſegments, the upper being broader and indented at the end where it is reflexed; the other three are erect and equal. It hath five awl-ſhaped ſtamina, three of which are ſhorter than the petal, and ſteril; the other two are longer, and adhere to the tube of the petal; theſe are fruitful in male duſt; they are terminated by roundiſh ſummits. In the center is ſituated a conical germen, ſupporting an erect ſtyle, crowned by a ſtigma with two lips, which cloſe after being fœcundated. The germen afterward becomes an oval capſule ending in a point, having two cells which are filled with ſmall ſeeds.

This genus of plants is ranged in the firſt ſection of Linnæus's ſecond claſs, intitled Diandria Monogynia, which includes thoſe plants whoſe flowers have but two ſtamina and one ſtyle, for he does not eſteem the three barren ſtamina as worthy notice.

The SPECIES are,

1. GRATIOLA (*Officinalis*) floribus pedunculatis, foliis lanceolatis ſerratis. Lin. Mat. Med. 18. *Hedge Hyſſop with flowers ſtanding on foot-ſtalks, and ſpear-ſhaped leaves.* Digitalis minima Gratiolata dicta. Mor. Hiſt. 2. 479. *Leaſt Foxglove, called Gratiola.*
2. GRATIOLA (*Virginiana*) foliis lanceolatis obtuſis ſub dentatis. Flor. Virg. 6. *Hedge Hyſſop with obtuſe indented leaves.*
3. GRATIOLA (*Peruviana*) floribus ſubſeſſilibus. Lin. Sp. Plant. 17. *Hedge Hyſſop with flowers ſitting cloſe to the branches.* Gratiola latiore folio flore albo. Feuill. Peruv.

The firſt ſort grows naturally on the Alps, and other mountainous parts of Europe. This hath a thick, fleſhy, fibrous, creeping root, which propagates very much when planted in a proper ſoil and ſituation, from which ariſe ſeveral upright ſquare ſtalks, near a foot high, garniſhed with narrow ſpear-ſhaped leaves placed oppoſite; the flowers are produced on the ſide of the ſtalks at each joint, they are ſhaped like thoſe of the Foxglove, but are ſmall, and of a pale yellowiſh colour. Theſe appear in July, but are ſeldom ſucceeded by ſeeds in England.

It is eaſily propagated by parting of the roots; the beſt time to do this is in the autumn, when the ſtalks decay; the plants ſhould have a moiſt ſoil and a ſhady ſituation, in which they will thrive exceedingly; but in dry ground they often decay in ſummer, unleſs they are plentifully watered.

This ſtands in the liſt of medicinal plants, but is very rarely uſed in England, though it is recommended by ſome good writers as a purger of ſerous and choleric humours.

The ſecond ſort grows naturally in North America, from whence I received the ſeeds. This grows naturally in moiſt places, where it riſes more than a foot high, but in England I have not ſeen it more than eight inches; the leaves are blunt, and indented at their extremities; the flowers are white, and come out from the ſide of the ſtalks, like thoſe of the other, but are not ſucceeded by ſeeds here. It may be propagated in the ſame manner as the firſt ſort, and requires the ſame treatment.

The ſeeds of the third ſort were ſent me from Carthagena, where it was found growing naturally in places where there had been ſtanding waters, which were then dried up; this plant grew about nine inches high, with a weak ſtalk, and the leaves placed oppoſite; they were about three quarters of an inch long, and half an inch broad, ſawed on their edges; the flowers came out ſingle on each ſide the ſtalk; they were white, and much ſmaller than thoſe of the firſt ſort, but were not ſucceeded by ſeeds, ſo the plant was loſt here.

GRAVEL and Graſs are naturally ornaments to a country-ſeat, and the glory of the Engliſh gardens, and things in which we excel all other nations, as France, Holland, Flanders, &c.

There are different ſorts of Gravel, but for thoſe who can conveniently have it, I approve of that Gravel on Blackheath, as preferable to moſt that we have in England; it conſiſting of ſmooth even pebbles, which, when mixed with a due quantity of loam, will bind exceeding cloſe, and look very beautiful, and continue handſome longer than any other ſort of Gravel which I have yet ſeen.

Some recommend a ſort of iron-mould Gravel, or Gravel with a little binding loam amongſt it, than which nothing, they ſay, binds better when it is dry; but in wet weather it is apt to ſtick to the heels of one's ſhoes, and will never appear handſome.

Sometimes loam is mixed with Gravel that is over ſandy or ſharp, which muſt be very well blended together, and let lie in heaps, after which it will bind like a rock.

There are many kinds of Gravel which do not bind, and thereby cauſe a continual trouble of rolling, to little or no purpoſe; as for ſuch,

If the Gravel be looſe or ſandy, you ſhould take one load of ſtrong loam, to two or three of Gravel, and ſo caſt them well together, and turn this mixture over three or four times, that they may be well blended together; if this is done in proper porportion, it will bind well, and not ſtick to the feet in wet weather.
